wheel, which, when released by the trigger, spun round, rubbing against the pyrites and causing sparks, which set fire to the priming. The wheel lock was, however, found to be complicated, expensive, and uncertain, so that the match-lock remained in use till the middle of the 17th century, when it was displaced by the flint lock, the earliest form of which, the "snaphammer," seems to have been invented about the end of the 16th century in Germany. In this lock the priming pan was provided with a steel cover and the cock held a flint, on pulling the trigger the cock fell, the flint struck the steel cover, forcing it back from the pan, evolving at the same time sparks, which fired the priming. During these developments of the lock the shape of the barrel was gradually changed, in 1621 the length of that of the musket was 4 feet, and the size of the bore such that twelve bullets weighed 1 lb. Soon after this the infantry soldier was supplied with a dagger,

FIG 1.—Hand Gun

which fitted into the muzzle and served as a pike. This was improved at Bayonne into the bayonet, and during the latter part of the 17th century was still further improved by the addition of a socket, so that the musket could be fired while the bayonet was fixed ready for use. Little change in firearms took place in the 18th century, but in 1807 a Scottish clergyman named Forsyth obtained a patent for priming with fulminating powder, an invention which, though it slumbered till 1834, was destined to cause a complete revolution in the mechanism of firearms. Early in the present reign its value was fully recognized, the magazine of detonating composition and the priming pan used by Mr Forsyth were improved into the cap and nipple, and the flint-lock was entirely superseded. At this point, the progress of invention renders it necessary for us to treat separately the two branches of the subject, and to divide shooting from military arms.

For sporting purposes smooth-bored shot-guns and grooved rifles are employed. Both are nearly always double-barrelled, and of late years the old muzzle-loaders have been almost entirely supplanted by the many breech-loading systems recently invented, which enable the sportsman to reload with greatly increased rapidity and uniformity, the latter quality being especially important in rifle shooting. The chief parts composing the arm are the barrel, the lock, and the stock. Barrels for sporting arms are made of four different kinds of material—Damascus twist, laminated steel, cast-iron, and mild cast-steel; besides these, common material is worked up into cheap barrels for exportation. Damascus twist consists of alternate rods of iron and steel placed one upon another, usually six of each kind are thus arranged, they are then forged and thoroughly welded to-

gether into a solid bar, which is afterwards rolled into rods, having a section about $\frac{1}{4}$ inch square. The rod thus formed is raised to a bright red heat, and one end of it is placed in a revolving chuck, while the other remains fixed; the turning of the chuck subjects the rod to a severe twisting throughout its whole length, so that at last it acquires the appearance of a screw having a very fine thread. Three of these rods are then placed together, the twist of one being in a contrary direction to that of the other two. They are then welded together into a bar, and rolled into a strip about $\frac{1}{4}$ inch in width. The thickness of this strip depends on the part of the barrel it is intended to form, if for the breech end it is made $\frac{1}{4}$ inch thick, it for the centre $\frac{1}{8}$ inch, if for the muzzle $\frac{3}{8}$ inch. These strips are now ready for coiling, which is performed by raising the strip to a bright red heat, fixing one end of it to a hook projecting from a taper mandril, which is placed in a machine and provided with a handle. On turning the handle the strip is wound round the mandril into a coil about 10 inches in length. The coil is then welded by about 3 inches at a time till the spirals unite to form a hollow cylinder, it is then hammered on a small mandril till the welding is complete. Three coils welded together end to end form a barrel, to which the three different thicknesses of metal above mentioned give a slightly conical form, approximating to the ultimate shape. About three-fourths of the material is cut away in the making, 1 lb of iron are used in the first instance to make a run of barrels, which weigh only 8 lb when the welding is finished, and only between 3 and 4 lb after boring and grinding. In the manufacture of laminated steel barrels the best quality of steel scrap, after thorough cleansing in a revolving drum, is mixed with a small proportion of charcoal iron. The mixture is heated in a furnace, and puddled into a ball, which is well worked up under a forge hammer. It is then drawn out under a tilt hammer, and rolled into strips of the required length and thickness, after which it is heated as above described. This material is much esteemed for its hardness and closeness of grain, but it does not possess the elegant marking and appearance of the Damascus twist. Steel iron for barrels was formerly made by putting a quantity of old horse-shoes or stube into an iron ring, welding them into a solid mass, and then rolling them out to strips of the requisite dimensions. Now a mixture of best wrought scrap, and sometimes steel scrap with stubs, is preferred, as giving more hardness and durability to the barrels. A description of the manufacture of cast-steel barrels will be found below, in connexion with military rifles. A sham-twist barrel is apt to impose on the purchaser, plain iron is cheaper than twisted iron, and sometimes a thin coil of twist is rolled round a plain inner tube, the whole is then welded together, and has all the appearance of a genuine twisted barrel. Other cheap barrels are made by rolling up strips of non-plate, and welding them together so that each barrel has a weld running down its whole length. As the breech end is thicker than the muzzle end, these barrels are usually made in two lengths.

In the rough state just described the barrels are sent Boring from the forge to the gunmaker, who bores them carefully and rings them out to nearly the finished size. He then turns them down at intervals, obtaining correct surfaces by means of inside and outside gauges. The barrels are then "stripped"—that is, turned down the whole length to correspond with the bore. For double guns two barrels are now bored together, near the muzzle and near the middle. At the breech the barrels are separated by a "steel lump." The axes of the barrels are not quite parallel to each other, but are usually adjusted to cross at about 40 yards from the gun. When packed together, a rib is soldered on down the entire length, and they are sent to be proved at the proof-

roof. house of the Company of Gunmakers at Whitechapel or Birmingham. The scale of proof is fixed by Act of Parliament, according to the size of the bore; it is considerably more than double the ordinary shooting charge. For the provisional proof, muzzle-loaders have the breech screwed in before firing; breech-loading barrels are pressed against a false breech. The second or definitive proof is less severe, and is carried out at a later stage, when the action of the breech-loader, or the percussion fitting of the muzzle-loader, is completed.

tools. The best stocks are made of English or Italian walnut, pieces of which reach the gunmaker roughly shaped. They are so cut that the grain shall run lengthways down the stock, and the wood is dried and seasoned to prevent warping. For expensive guns, much attention is paid to beauty of mothing and depth of colour. A considerable variety of tools is employed in shaping the stocks and cutting out the beds for locks, processes which, for Locks, sporting pieces, are performed by hand. All parts of the lock except the plate are of steel, and reach the gunmaker hammered into shape. The lock-plate is of wrought iron, case-hardened. The parts are worked to fit by hand with a number of special tools. Bar locks are those which have a forward action, arranged so that the main-spring fits under the bar below the breech end of the barrels; back-action locks have the spring reversed, so as to extend down

FIG. 2.—Early breech-loader. C, pinfire cartridge; S, single grip.

the hand or grip of the stock. The remaining portions of the gun are termed the furniture. They are the heel-plate which covers the butt, the break-off into which the breeching hooks for muzzle-loaders, the trigger plate, the trigger guard, the hammers, the escutcheons, and bolt fastening the barrel to the stock, &c. For breech-loaders the action is a most important part of the furniture. The ingenuity of gunmakers has devised an immense variety of actions, and every day sees progress made in strength and simplicity. M. Lefauchoux is entitled to the credit of inventing the modern sporting breech-loader. His first hit on the combination of a pair of barrels open at the breech, playing on a hinge and abutting against a false breech (fig. 2), with a strong-based cartridge-case containing powder and shot ready for firing, and supplied with its own means of ignition. His early guns were found weak in the fastening of the barrels to the stock, while the mode of igniting the charge was far from perfect.

It consisted of a pin passing through the upper part of the cartridge case, the point resting just above a percussion cap placed at the centre of the base of the charge; the hammer fell on the head of the pin, driving the point into

the cap, and exploding the detonating composition. The gas was found to escape through the pin hole, the extraction was sometimes difficult, and a fall on hard ground would occasionally explode the cartridge; for these reasons the pin system was superseded by the central-fire method (fig. 3), in which the base of the cartridge case was made to hold a small anvil, on to which the cap was driven by a needle or striker passing through the false breech, and receiving the blow of the hammer. Fig. 4 shows a central-fire gun, having the action considerably strengthened by the double grip. In this system the extraction is accomplished

FIG. 4.—Central-fire gun. C, central-fire cartridge; L, lever; W, washer; S, screw.

automatically, by a piece of steel fitting between the two barrels, and so cut as to clip the rims of both cartridges. To this extractor is attached a rod which runs down between the barrels through a hole in the steel lump as far as the hinge; on opening the joint the rod is driven backward, carrying with it the head and forcing the cartridge cases out of the barrels. Guns on the central-fire system afford no indication of being loaded; extraction and loading are, however, so rapid and easy that every sportsman should invariably withdraw the cartridges on laying down his gun, and reload on again taking the field. Hammers sometimes

FIG. 5.—Improved breech-loading action.

catch in the brambles, or even in the clothes of the shooter; even the double grip has been known to yield under the effect of the heavy charges now used. The latest guns leave little room for improvement in respect to the action. Fig. 5 shows one of the newest developments. The hammers are abolished altogether, the striker being a needle in the interior, which is driven against the cap of a central-fire cartridge by a spring when the trigger is pressed; a lever on the top is pushed aside by the thumb, liberating the catch which holds the barrels against the false breech; the barrels then drop from the hinge, and are open for loading. On raising the barrels, the action snaps to, and holds them fast; the dropping of the barrels causes an extractor to withdraw the empty cartridge cases. A key at the side regulates the cocking and safety of the lock and striker.

FIG. 3.—Central-fire cartridge.

The sizes of barrels are designated according to the weight of the solid spherical lead ball which will just fit them, and hence their diameters vary inversely as the cube roots of their numbers. In the case of No 12 bore, the ball fitting it weighs 12 to the pound, and measures 729 in in diameter. Once bullets (No 16) fit a bore of 663 in in diameter.

Barrels were formerly bored cylindrically, but the experiments of gunmakers led them to suppose that better shoot ing could be obtained by boring to shapes de parting in various ways from the simple cylinder. The first modification introduced consisted in enlarging the breech end slightly for about 10 inches, subsequently the last few inches at the muzzle were enlarged also, so that the barrel really consisted of two fusils of cones, having the smaller ends together,—the position of the narrowest part, like many other matters, was dependent on the fancy of the gunmaker. Of late an attempt has been made to reduce the interior form of the barrel to something like a system, and several kinds of "choke" boring have been introduced. The object to be attained with a shot-gun is to so arrange the charge that the pellets shall be uniformly and thickly distributed round the mean trajectory, and shall also

Form of barrel bore in shot guns

Fig 6

occupy a small space longitudinally. In fig 6 a side view of the charge as it passes through the gun is given, *ab* being the mean trajectory. Exact experiments to determine the proportions of the cloud of shot fired from different guns do not exist, but, judging from observation, they will usually not depart greatly from those of the figure.

In fig 7 is seen the appearance of the target after being struck by the charge. The test of excellence is regularity of pattern, combined with penetration, that is, a circle of 30 inches diameter should be so pitted by the shot at 40 yards range that gaps of the size of a small bird should nowhere exist, while the individual pellets should retain force enough to penetrate a certain number of sheets of brown paper. As the shot pass along a barrel driven violently forward by the powder gas, it is probable that the edges of the charge are retarded by friction against the sides of the bore, so that the centre portion extricates itself rather sooner than the edges, and travels with a slightly higher velocity. Supposing the charge to rotate at an average velocity, on reaching the object fired at, of 300 feet per second, and the leading pellets to have gained 10 feet on the hindmost ones, so that the charge is distributed over a length of 10 feet, a period of time of $\frac{1}{30}$ of a second will elapse between the blows of the first and last pellet. If the object be stationary, this interval will be almost imperceptible, and the pattern made on the target by the impact of the shot will exhibit no trace of it. But if the object be a bird flying across at the rate of 60

Fig 7

feet per second (about 40 miles an hour), it will traverse a space of 2 feet in the interval, and so will not receive the

charge at all in the manner shown on the target. Figs 8, 9, 10 show some of the choke bores fancied by different makers.

Fig 8—Plain choke

Fig 9—Double choke

Fig 10—Green's choke

The manufacture of sporting rifles does not greatly differ from that of shot guns. Greater strength and weight of rifle barrel are necessary to resist the pressure of the charge, withstand the wedging action of the bullet, and deaden the recoil. The breech-closing action also demands greater strength, but the general arrangements are not different in principle. Rifles for sporting purposes differ from military pieces in being double-barrelled, and in requiring accuracy and penetration at short ranges, instead of a flat trajectory at very considerable distances. Hence they generally resemble the shot guns in their action, and fire more powder in proportion to the weight of the bullet than military rifles.

In fig 11 the table grip snap action is shown as especially devised for rifles firing heavy charges. In addition to the holding power thus provided, a piece is sometimes made to extend from the rib between the barrels, terminating in a projection which catches in a recess in the top of the false

Fig 11—Table grip snap action

No scientific or crucial experiments have as yet been carried out to determine the true action of these forms, but the editor of *The Field* is now preparing mathematical and undeviating to approach the subject in a scientific manner. The general principles, so far as they can be gathered at present, are, that enlarging or relieving the barrel slightly reduces the friction and allows the shot to acquire greater velocity, while choking the barrel at the muzzle has the effect of directing the outer pellets inwards, and so concentrating the charge.

breech, when the barrels are closed; or the catch shown in fig. 5 may be adopted. Some makers, instead of using the hinge principle introduced by Lefaucheur, close the breech in other ways; thus in the Henry action the barrel does not move, but is closed at the breech end by a sliding vertical block, which is depressed for the admission of the cartridge by a lever underneath the trigger guard; the striker passes through this block, which on being lowered extracts the cartridge. The power of a modern rifle is limited only by the power of the shooter to withstand the effect of recoil and to use a heavy piece. The momentum of the bullet forwards up to the time of its leaving the muzzle is equal (neglecting the weight and motion of the gas generated by the powder charge) to that of the gun backwards at any instant. Supposing the gun to weigh 150 times as much as the bullet, it will acquire a velocity against the shoulder equal to the 150th part of that acquired by the bullet. Practically it is this velocity which measures the severity of the recoil, and the heavier the gun and the more powerful the shooter the more momentum can he afford to impart to his bullet. This momentum may be composed of high speed and low weight, or of low speed and high weight. A light bullet starting with a high velocity travels fast at first and drops but little at a short range; it especially, however, suffers retardation by the resistance of the air, and would soon be beaten by a heavier bullet of the same diameter starting with the same momentum. The Express rifles carry out this principle with great completeness, employing heavy powder charges and imparting very high speed to a light bullet, so that a range of about 130 to 180 yards is traversed with a drop not exceeding 1 foot. Fig. 12 shows the nature of bullet generally used for these pieces; the hollow in the centre permits the lead to expand and flatten out on striking, inflicting a wound of great severity. Explosive bullets are also employed by some sportsmen. In fig. 13 are

Fig. 12.

shown rifle cartridges loaded ready for use. The solid brass-drawn case is now almost universally adopted, both for sporting and military purposes. The Martini-Henry rifles used by the British army, however, still use the soft brass-crimped case.

FIG. 13.—Rifle cartridges.

shown rifle cartridges loaded ready for use. The solid brass-drawn case is now almost universally adopted, both for sporting and military purposes. The Martini-Henry rifles used by the British army, however, still use the soft brass-crimped case.

Military rifle.

Military Rifle.—The principle of rifling small arms seems to have been discovered about the beginning of the 16th century, but does not appear to have been employed for warlike purposes till the middle of the 17th. In 1680 each troop of life-guards was supplied with eight rifled carbines. In 1800 the 95th regiment, now the rifle brigade, was armed with a 20-bore muzzle-loading rifle. The difficulty of loading a rifle after firing a few rounds was the great obstacle to its use in the field. Several methods were devised of providing anvils at the bottom of the bore on which a loose ball dropped in could be hammered to fit the grooves, but the principle of expansion by the action of the

powder was not brought forward till 1836, when Mr Groomer submitted an egg-shaped bullet, having an opening at one end to receive a caual plug, which when driven home by the gas expanded the bullet into the grooves. Shortly after this the French chasseurs were armed with a rifle throwing an elongated bullet with a hollow-coned base. This was improved by Captain Minié, who added an iron cup to fit into the cone and expand it when forced home by the gas. For this cup a wooden plug was substituted in the three-grooved Enfield rifle in 1855. About this time Sir J. Whitworth brought forward his hexagonal rifling, the guiding idea of which was that every part of the hexagon except the actual corner should do its share of the work of giving rotation. He proposed for a barrel 39 inches long a bore of .45 inch, having one turn in 20 inches. This was intended to be suitable either for an expanding bullet, or for one possessing an easy mechanical fit. The length of the bullet was increased, and the form thus modified suffered much less from the resistance of the air than the previous patterns. The question of breech-loading for military weapons now began to assume importance. About 1841 the Prussians had adopted the needle gun, a breech-loader on the bolt principle. It was a rough weapon compared with the pieces lately introduced, but a great advance on any known at the time. A conical bullet rested on a thick wad behind which was packed the powder, the whole being enclosed in strong lubricated paper. The detonator was in the centre of the hinder surface of the wad, so that to explode it a needle had to be driven forward from the breech through the base of the cartridge and through the powder. This was accomplished by the action of a spiral spring, when set free by the pulling of the trigger. This arrangement possessed many defects: the gas escaped freely at the breech; the long needles rusted and broke; the springs failed; and the weight of the piece was excessive. Such failings caused the sterling merit of the principle to be underrated, and it was not till 1864 that a committee of officers recommended the introduction of breech-loading arms for general adoption in the British army. The triumph of Prussia in the Seven Weeks' War with Austria in 1866 at once drew attention to the urgency of the case, and caused all civilized powers to re-arm their troops. In England the Enfield rifles (three-grooved expanding bullet muzzle-loaders) were converted into breech-loaders by the adoption of the Snider method, which consisted in cutting away 2 inches of the upper part of the breech end of the barrel so as to admit the cartridge, which was pushed forward into a chamber formed by enlarging the end of the bore. A block, opening on a hinge, was then shut down to fill up the space behind, forming a false breech against which the base of the cartridge abutted. The striker consisted of a needle passing through this breech block; when struck from behind by the hammer it was driven against a cap in the base of the cartridge, exploding the charge. By this means the existing rifles were rapidly converted, and the army was provided with a breech-loader of satisfactory efficiency should any emergency arise. Proposals were then invited, and a number of inventions submitted, the result of which was that in 1869 the combination of the Martini breech action with the Henry barrel was decided on for future manufacture, and the whole of the British army is now provided with these weapons (see figs. 14, 15, 16, 17). The general principles of manufacture are the same for all kinds of military breech-loading rifles. It will be sufficient to give the details of one *in extenso*.

The manufacture of the Martini-Henry rifle, as carried out at the Government factory near Enfield, involves 2004 separate operations which have to be performed on each rifle before it is complete for issue. This number is subject to slight variations caused by changes of pattern from time

to time. It will be sufficient if the principle of those operations are described, without entering minutely into details.

The rifle is composed of three parts—the barrel, carrying the sights, the stock, into which fits the cleaning rod, the body, containing the lock and breech action. The soldier is also provided with a bayonet to fit on the muzzle.

FIG. 14—Mauser breech action (closed)

The barrel is made of mild steel manufactured on the Siemens principle. Cylinders of this material, 16 inches long and $1\frac{1}{2}$ in thick, are supplied by contract, and tests are made of a proportion from time to time. These cylinders are first rolled in the factory to a long cone, having slightly greater dimensions than the exterior of the

FIG. 15—Mauser breech action (open)

finished barrel. The cylinder is heated in the furnace and passed straight through a series of eight pairs of rolls, each pair is grooved to receive it, the grooves becoming narrower and shallower as each successive pair is reached. The pairs are alternately vertical and horizontal, when they are in full work they can roll about 250 cylinders per hour.

FIG. 16—Heavy barrel

The cone is next placed between friction rollers, these are set at a slight angle, so that as revolving they pass the cone along slowly. It emerges from their clutch polished with the compression, and showing their action by a close spiral traced on the surface. We have now a solid piece of mild steel, slightly thicker than the barrel, fairly straight and thoroughly well-consolidated.

The next step is to obtain true bearings for boring the interior and turning the exterior. The cone is placed in a clamp milling machine, and the ends milled down. This operation requires some judgment, the milling down of the ends must be so performed that the centres shall be approximately true centres, that is, the amount of metal to be subsequently turned down off the exterior of the barrel shall be about equal all round.

The ends, when milled down, serve for bearings by which the cone is next held horizontally, and drilled in a double acting machine for $1\frac{1}{2}$ in, these act as

centres when the barrel is placed vertically and drilled through from each end. These tools are used, the last being of slightly greater diameter than the others. A shoulder is left in the centre to avoid the inconvenience of the tools from opposite ends not exactly meeting in the middle, as might be the case with the long slender drills necessarily employed. This shoulder is removed by a square tapered tool or "bit." We have now a cone slightly larger than the barrel, with a hole through it 435 in diameter. This hole is then bored out to 444 inch. Having now got a true inside, the next step is to obtain a true outside from it.

The cone is placed vertically in a machine, the lower end fitting accurately on a pin, the upper end passing loosely through a hollow chuck, which revolves round a centre in truth with the centre of the pin and the axis of the bore of the cone, the exterior of the cone, being slightly irregular, will be out of truth, sulphur tinfoil is melted and poured into the hollow chuck, filling up the space between the interior of the chuck and the exterior of the cone, and hardening on cooling. The chuck then holds the cone by the outside in truth, and serves as a bearing. The cone is then placed in a lathe, and two or three short cuts taken off the outside as bearings for the rough turning. This is called "spotting." It is now rough and finish turned, the outside becoming concentric with the inside, and the cone becomes a barrel.

It is next tested for truth of interior. Two tests are being employed,—the first being that by *shading*. The barrel is placed in a rest, so arranged that the eye looking through

the tube sees the straight line of the top of a window cutting horizontally across the aperture a little above the centre. If the barrel is accurately straight and brightly polished, the shadow thrown by the dark window-frame down the tube appears as in fig 18. The interior circle shows the window as seen through the barrel, with the dark frame cutting across.

The next circle shows the shadow extending in a cone from A to B and C. This shadow is quite dark, and AB, AC are quite straight. BC is a portion of the arc cutting off the shadow sharply at a point half way down the barrel.

There are two outer circles extending to the eye, and approximately surrounding the sketch in shading. If the barrel is untrue in interior surface, or bent, the cone will at once lose its regularity, and therefore A, B, C, G will no longer be straight. Should they be irregular, the barrel is "set" by striking with a hammer or chisole mallet across a setting block.

The barrel is next placed in a machine, and a horizontal spindle is run through it, on this spindle are two close-fitting gauges, one in the centre and one at the end, the barrel is then caused to revolve on the spindle, and an indicator with a long arm recording small graduations is inserted at the free end between the spindle and the barrel, any irregularity of turning is multiplied 300 times by the long arm, and becomes at once apparent.

After passing these tests the barrel is finish-turned, the back sight is soldered on and screwed, and the fore sight is brazed on, the size of bore is then gauged, after which the process of polishing is completed and the barrel is ready for rifling.

Rifling. The rifling consists of seven grooves of the form shown in fig. 17. The twist is such that the bullet makes one complete revolution while travelling 22 inches, that is, one turn in 49 calibres of 0.45 in., to employ the phraseology generally applied to the rifling of cannon. Each groove is cut separately by a tool which acts when pulled, it forms the groove by five successive cuts, being forced to project a little more at each cut, it thus passes thirty-five times up and down the barrel to complete the rifling, which can be done in half an hour. The size of bore is now finally tested, it must be between 0.449 and 0.451 inch. The rifling is similarly tested, and the twist gauged.

Chambering. The breech end of the barrel is next chambered out to receive the cartridge, which is of the kind known as "bottle-shaped." The exterior of the breech end is of "Nocek's" form, the upper surface being a flat, true to the bore. This fit guides all the fittings, the barrel is placed in a machine true to the flat, and the sights are gauged for line and elevation. No allowance is made for the deflexion due to twist of rifling, it being very slight. The barrel is lastly screwed at the breech end to fit the body.

Proofing. Each barrel is twice subjected to proof by powder, once before rifling, once after. Sixteen are placed in a cast-iron frame, a temporary steel screw, furnished with a vent, closes each breech end, which rests against a leaden bar. The barrels are loaded from the muzzle, a train of powder ignited by a cap fires them simultaneously, the bullets are caught in a hollow cast iron receiving frame, shaped like the shell of a shell. The charge for the first proof is 7½ drs (= 205 grs) of powder and a bullet weighing 715 grs, secured by a half inch cork was forced down over it. The second proof is the same, except that only 5 drs (= 137 grs) of powder are used. The service charge is 85 grs of powder with a bullet of 180 grs.

The barrel when finished is browned by being coated with browning mixture, and caused to rust in a clean tank, it is then brushed with wire brushes. This process is repeated four times, after which the exterior is oiled over. The browning mixture consists of—

Spirits of wine	5 oz	Colicouze sublimate	4 oz
Spirits of nitre	8 "	Blue vitriol	4 "
Tincture of steel	8 "	" Water	1 gal
Nitric acid	4 "		

Stock. The stock is in two parts,—the butt and the fore-end. They are of Italian walnut wood, and are supplied roughly shaped. They are tested for straightness of grain, weight, as indicating strength, "shakes" or cracks, "galls," caused by injuries over which the wood has grown, softness (which would cause absorption of moisture and consequent rusting), by putting a shaving into a solution of nitrate of silver,

and also for appearance. Those accepted are thoroughly seasoned by keeping, or dried in a desiccating chamber, warmed by hot air, they then go to the shaping machine, where they are cut to size by revolving cutters, making 4000 revolutions per minute, and are afterwards turned in copying lathes, hollowed out by copying gonges, and bored to take the fittings. They are then tested, machined, hand-finished, and oiled up.

The body is of mild steel, it is stamped out from the Body bar, it is then drifted through by a slightly tapered bar carrying a succession of cutters on it. The front part of the body is then screwed to suit the screw on the barrel, so that when home it shall fit accurately to the breech end. The lever, and indeed all parts except screws and springs, are stamped out of solid bar. Each part is milled by machinery to a correct fit, every fitting is interchangeable, and nothing is marked for selection to fit anything else. Each part is browned in the same way as the barrels, or blued.

On completion all parts are taken to the assembling room, where they are fitted together, screwed up, and turned out as finished rifles, after which they are taken to the practice ground, and tested for accuracy and extraction of cartridge by being fired from a rest at a target, the range being 500 yards.

The bayonet consists of a steel blade welded to a Davenport wrought-iron socket. Steel of a superior quality being used, it is supplied in bars, is cut into lengths, and is welded by the aid of a box to a short rod of rolled iron. The two are set put together as to form a right angle, the steel bar is put into a "Ryding" machine, which gives it a great number of rapid blows, and shapes it roughly into a blade. It is then rolled and cooled gradually under charcoal and coal dust for annealing purposes. The socket is then drilled, and the blade ground. They are then bent into position and become a bayonet. Turning and finish-boring complete the sockets, while the blades are fine-ground, hardened, tempered, tested, and polished. The sockets are then browned and adjusted to the rifles.

About 1400 operatives are employed at the Government factory, each Martin-Henry rifle costs about 48s, all expenses included, and to render the establishment thoroughly remunerative, the out-turn should be about a rifle a week per man.

The systems of breech-loading muskets employed by different nations are shown in the following table.—

Country	Notice	No of Rounds	Action	Remarks
Austria	Wendel	5	Block rotating sideways	
Bavaria	Weder	4	Falling block	
Denmark	Remington	5	Block hinged to rear, supported by a cam	
England	Martin Henry	4	Falling block	
France	Gras	4	Sliding bolt	
Germany	Mausner	4	Do	
Italy	Vetterli	4	Do (magazine gun)	
Russia	Bedan	5	Block hinged to front (old)	
Spain	Remington	5	Sliding bolt (new)	
Sweden	Do	5	Block hinged to rear, supported by a cam	
Switzerland	Vetterli	4	Falling block (magazine gun)	
Turkey	Martin Henry	4	Falling block	
United States	Springfield	5	Block hinged to front	

It will be noticed that the Vetterli gun, used by the Italians and Swiss, is a repeater or magazine gun. It contains a supply of eleven cartridges arranged in a tube running under the barrel, and forced by a spring into the loading position one by one, as the previously fired empty one is extracted. The arm can thus fire twelve rounds with great rapidity without reloading, it can also be used as an

ordinary breech loader, a fresh cartridge being inserted at every round, and the magazine kept constantly full. Thus is no doubt a great advantage under certain circumstances, but entails grave inconveniences. Thus the Vetterli gun, with magazine full, weighs just half as much again as the Martini-Henry, and gives less energy to its bullet at the muzzle in the proportion of 5 to 8, a proportion which increases to the disadvantage of the magazine gun as the range increases. Still, for a *mêlée*, and at short ranges, the Vetterli is no doubt a very formidable piece.

These considerations have led the Government of the United States to make trials of a number of magazine guns, of which one, the Hotchkiss, has been selected for adoption. The working of it is shown in fig 19. The magazine is contained in the stock, and holds five cartridges, a sixth being in the chamber ready for firing. These cartridges are the same as those used for Government Springfield rifles, as they are pushed successively into the loading position by a spiral spring till the magazine is empty, or a fresh cartridge

FIG 19—Hotchkiss Magazine Gun

can be inserted after each round as in an ordinary breech-loader. The action of bringing the knob-handle upright and withdrawing the bolt extracts and throws out the emptied cartridge to the side, the next cartridge is then pushed up into the loading position by the spring, and is forced into the barrel when the handle presses the bolt forward, this action also cocks the piece, but the striker cannot reach the cartridge till the knob-handle is turned down, and the bolt thus locked in position. The weight of the piece fully loaded is 94 lb. Trials of this weapon are about to be made by the English Government.

Of all the military rifles adopted by the various Governments, the Martini-Henry is the most powerful, the practical test is underwent in Turkey, where a cheap gun of this pattern was supplied on contract by an American firm during the war of 1877-78, was most satisfactory.

Pistols—These handy little weapons were formerly made as single or double-barrelled smooth-bored muzzle-loaders, and their system involved no departure in principle from the ordinary firearm of the day. The introduction of the revolver as a practical weapon was a great step in advance, the idea is old, and roughly constructed weapons on the same plan have long existed in museums of old arms, Colonel Colt of the United States revived it, and is the father of the modern revolver. In his pistol a revolving muzzle-loading cylinder contains a number of chambers, usually five or six, bored from the front parallel to the axis, the back of the cylinder is left solid, and forms the breech, a nipple is screwed into each chamber. As the cylinder revolves, each chamber arrives at the top, and is then opposite to a barrel, the pistol is cocked by the thumb, an action which locks the chamber against the barrel, so that the two form a continuous bore, the trigger is pulled in the usual way, and the hammer brought down on the upper nipple, exploding the charge in the top chamber. The action of recocking brings the next chamber into

position. When on half-cock, the cylinder revolves freely. Since Colt's time great improvements have been made in these handy weapons, the trigger was made to cock the hammer, turn the cylinder, and fire the charge by one continuous draw, this arrangement enabled the shooter to fire all the shots very rapidly without lowering his hand, the strength of manning required, however, rendered it very difficult to shoot with any degree of accuracy, especially as the exact moment when the hammer would fall was hard to estimate. A second improvement gave the shooter the choice of cocking the hammer and firing it in the usual way, if he preferred it. The next step was to make the chambers breech-loading, by boring them right through, and packing the powder and bullet in a strong based cartridge, carrying its own ignition. In pistols constructed on this plan the chamber arriving at the top is brought against a false breech through which the striker is driven by the hammer. In the latest pattern of this pistol, the cylinder and barrel open away from the false breech on a hinge underneath, the action of opening throws out the empty cartridge cases. If the user is on horseback, he thrusts the barrel muzzle downwards into his breast, belt, or holster, the hinge remaining open, fresh cartridges are taken out of the pouch and placed in the chambers, the breech is closed sharply on the hinge and is held by a snap-catch, the pistol is then withdrawn ready for use. All this can be very quickly done with one hand at full gallop.

MACHINE GUNS

This term comprehends all weapons made to fire a rapid succession of bullets from a stand or carriage, so that, while requiring but two or three men to work them, they may throw in a fire equal to that of a detachment of infantry. In the Franco-German war of 1870 a species of *mitrailleuse* was largely employed, and when used under favourable conditions attained fair success. It consisted of a number of barrels (usually 25 or 37) secured in a frame round an axis, and parallel to it. The barrels were open at the breech, and were loaded by a disc placed to correspond with them containing a cartridge in each chamber. This disc was placed against the breech end of the barrels, the false breech containing the strikers was

FIG 20—Gatling Gun

held firmly against it, and the whole of the charges were exploded at once. This arrangement had many defects. The recoil of so many charges fired simultaneously required strength and weight, at short ranges the bullets all went to the same spot, the number of rounds could not be regulated at pleasure, and only volleys could be fired. The Gatling machine gun, which first appeared in the United States, was vastly superior to the *mitrailleuse*, and speedily obtained entrance into the armies of most of the civilized powers. Figs 20 to 26 show the general construction of the weapon. In fig 20 the Gatling is ready for firing. A block of ten barrels is secured round an axis, which is fixed in a frame *aa*. On turning the handle *b* (fig 21), the

spindle *gy* causes the worm *f* to act on the pinion *sz*, making the axis and barrels revolve. A drum *T* (figs. 20, 24, 25)

the carrier, which consists of ten grooves or chambers *M* (fig. 23) corresponding to the ten barrels. The construction of the lock is shown in fig. 28. It consists of a bolt, through

Fig. 21.

Fig. 22.

is placed on the top at the breech end of the barrels over a hopper, through a slot in which the cartridges drop into

Fig. 23.

Fig. 24.

Fig. 25.

which passes a striker driven by a spiral spring. *AAAA* is a cam, sloping as in the drawing, which it must be understood represents the circular construction opened out and laid flat. As the barrels, carrier, and locks revolve, the

FIG. 26.—Lock of Gatling Gun.

slope of the cam forces the locks forward and backward alternately. At position I, the cartridge has just fallen into the carrier, the lock and bolt are completely withdrawn. At positions II, III, IV, the cam is forcing them forward,

so that the bolt pushes the cartridge into the barrel. At IV, the cocking cam *R* begins to compress the spiral spring, releasing it at V. Position VI shows the cartridge just after firing; the extracting hook, omitted in the previous

positions, is here represented in the act of clutching the base of the cartridge case, which is withdrawn as the lock rotates down the slope of the cam, till at X it falls through an aperture to the ground. The line *ab* marks the commencement of the rilling. In fig 20 the drum T consists of a number of vertical channels radiating from the centre. The cartridges are arranged horizontally, one above the

other, in these channels, bullet ends inward. The drum revolves on the pivot *b* (fig 23), and the cartridges fall through the aperture D. When all the channels are emptied, a full drum is brought from the limber, and substituted for the empty one. Each barrel fires in turn as it comes to a certain position, so that by turning the handle quickly an almost continuous stream of bullets can be

FIG 27.—Nordenfält Machine Gun. 1-10, parts of frame, 11, breech plug, 12, striker, 13, extractor, 14, cartridge receiver, 15-18, 23-31, lock and trigger parts, 19-22, locking action, 32-36, loading action, 36-39, cartridge receiver, 40, cover, 41-44, parts of hand lever, 45-49, traversing action, 50-55, elevating and tramping action, 56, 57, hopper and slide.

ejected. An experimental pattern of Gatling has been lately used, fitted with a multiplying arrangement which could be made to fire nearly 1000 shots a minute. In fig 21 an automatic traversing arrangement is shown, which can be put in or out of gear as desired, and by means of which the amount of traverse can be regulated. The spindle *gg* turns the wheel A, projections on which act on

the aim F, and traverse the breech through a small arc, thus spreading the bullets laterally over the required front.

Effective though this piece is for land service, especially in defending approaches, it is scarcely suitable for the navy, as the mobility of the boats or vessels carrying it causes immense waste of ammunition, it being impossible to hit more than a few rounds at the object before an important

FIG 28

change of direction occurs. The Nordenfält machine gun, shown in figs 27 to 31, is found specially suitable under these circumstances. The barrels are here placed horizontally, and have no movement. A box containing the locks, bolts, strikers, and spiral springs, one of each corresponding to each barrel,

FIG 29

moves straight back wards and forwards when worked by the handle of the lever on the right. When the box is drawn back the cartridges fall from the holder on the top into the carriers simultaneously. When the box is pushed forward the bolts push the cartridges into the barrel, cocking catches compress the spiral springs, the lever releases the catches one after the

other at very minute intervals of time, and the cartridges are fired in rapid succession. In this piece, careful aim can be taken from a moving platform, and at the right

FIG 30

FIG 31

moment the barrels can be fired at the object almost simultaneously, they could be made to fire at the same instant,

but in this case the advantage of being able to fire single shots would be lost, and the recoil would be increased. This gun would probably never be able to fire with such extreme rapidity as the experimental form of Gatling mentioned above, but it could be made to fire six or seven hundred rounds a minute. It is generally considered that a machine gun should be able to fire easily two hundred rounds in half a minute.

ORDNANCE

Ordinance. The manufacture of ordnance is a much more scientific and complicated study than that of small arms. As the forces increase in magnitude and intensity, while the ultimate strength of material remains constant, the necessity of adaptation of means to ends grows *per se* with the gun. In producing a piece of ordnance, two distinct sets of conditions are involved—those belonging to its actual construction, and those by which its proportions are regulated. In constructing a gun, the material must be so selected and disposed as economically and safely to sustain the effect of the forces developed by the charge, in designing a gun, it is necessary to know the nature and direction of the forces which will combine to produce the desired ballistic results. The two sets of conditions are as distinct as those involved in the separate operations of writing and printing these articles.

Construction. Nearly all the accurate knowledge yet obtained of the true action of gunpowder has been acquired within the last twenty years. The general idea previously held was that the explosion was instantaneous, and that the more violent the powder the greater would be the velocity of the projectile. The mode of proving the quality of the explosive was to place a small quantity in a short mortar, and to measure the distance to which it projected a light shell—a test altogether wrong in principle, as will be shown later on. No accurate idea had been formed of the true pressure of the powder gas on the bore during discharge, but it was understood that a gun was subjected to two principal strains or stresses—a circumferential tension tending to split the gun open longitudinally, and a longitudinal tension tending to pull the gun apart in the direction of its length.

Homogeneous guns. When guns are made of cast metal, and are, in fact, homogeneous hollow cylinders, a limit is soon reached beyond which additional thickness is practically useless in giving strength to resist the circumferential tension. Supposing the metal employed to be incompressible, each concentric layer would take up a strain on discharge inversely proportionate to the square of its distance from the axis of the bore. Every metal, however, is compressible as well as extensible, and hence the exterior always affords more support to the interior than the foregoing rule indicates. The great aim then of a gunmaker is so to select and arrange his material that the exterior shall take up as much as possible of the strain thrown upon the interior.

In America, Captain Rodman introduced a method of casting guns hollow and cooling them down from the interior, so that the inner portions being first solidified were compressed and supported by the contraction of the outer parts when they subsequently cooled down. Thus, on discharge, the compressed inner portions expanded under the action of the powder gas to or beyond their natural diameter, throwing at once the strain on the outer portions which were already in a state of tension. But however well cast iron may be disposed, it is naturally too weak and brittle for use with heavy guns, and those nations which employ it thus do so because it is comparatively cheap and easy to manufacture, and not because it is the best material. Austria and Russia have of late years made light guns of

bronze cast in chill, and subjected to the wedging action of steel mandrils driven through the bore. The several layers of the metal are thus placed in a state of tension as regards the exterior, and of compression as regards the interior. At the present day systems of building up guns have been devised so that each portion of the metal is made to bear its fair share of the strain.

The longitudinal tension is usually less important than the circumferential stress. It is considered to be provided against in homogeneous guns if the metal is as thick over the bottom of the bore as round the end. The strain is now measured by calculating the total pressure of the powder gas on the bottom of the bore, and comparing it with the area of the transverse section of the gun at the same places. This is not absolutely correct, but, practically, the chief modes of gun construction now adopted leave a considerable margin of strength in this direction.

As William Armstrong first successfully employed the built-up principle of initial tensions for all parts of a gun. In his gun system, wrought-iron coils are shrunk over one another, so that the inner tube is placed in a state of compression and the outer portions in a state of tension, an endeavour being made to so regulate the amount of tension that each coil should perform its maximum duty in resisting the pressure from within. Further, he arranged the fibre of the several portions so as to be in the best positions for withstanding the pressure. It must be noted that wrought-iron has about twice as strong in the direction of the fibre as across it. He therefore constructed the exterior of his gun of coiled bars of wrought-iron welded into hoops and shrunk one over the other, thus disposing the fibre to resist the circumferential strain. These outer coils were shrunk over a hollow cylinder of forged iron, having the fibre running lengthways so as to resist the longitudinal strain. Within this cylinder or forged breech piece was placed a steel tube, gripped in like manner by shrinkage. This grand shrink principle of modern gun construction is carried out by turning the inner coil in a lathe to an exterior diameter slightly greater than the interior diameter to which the outer coil is bored. The outer coil is expanded by the application of heat, and slipped over the inner one. It contracts on cooling, and if the strength of the two coils is properly adjusted, the outer will remain in a state of tension, and the inner in a state of compression. On this view, the ideal gun would be constructed of a vast number of exceedingly thin rings so shrunk over each other that, on discharge, each should be equally strained. An attempt has been made by Mr Longridge, M.I.C.E., to approximate to this condition by winding steel wire under tension round a steel tube. This system, though possessing much ingenuity, has never made way, and might possibly be found wanting in longitudinal strength.

Great success attended the early introduction of the coil principle. Guns of considerable size were made, the largest weighed as much as 23 tons, and projected a 600-lb shot with a fair velocity. It was found, however, that much difficulty attended the accurate shrinking of a number of thin rings, and that occasionally one or more of the outer ones would be strained to cracking, while the inner ones were intact. The original mode of construction was therefore modified, as experience was gained in the Government factory at Woolwich. Acting under General Campbell, R.A., Mr Fieser, M.I.C.E., thickened the coils, and extended them up to the breech piece, it being found that the longitudinal disposition of the fibre in that part was not required to sustain the longitudinal strain, and that the steel tube forming the bore was better supported by coils.

The manufacture of ordnance at Woolwich and Elswick may be briefly described as follows: Steel cylinders, slightly larger than the exterior dimensions of the inner

tubes, are supplied by contractors. They are tested for quality of metal, and toughened after being bored by being raised to the temperature shown by the tests to be most suitable to the particular cylinder, and then plunged in oil. They are subsequently tested by water pressure at 4 tons

Fig 32

per square inch. The tubes are not bored quite through for muzzle-loaders, a solid end is left to form the bottom of the bore. The rest of the gun is made of wrought iron. The material is chiefly received from the contractor in the form of wrought scrap, but a certain proportion of iron

Fig 33

puddled in the works is used also. Blooms of these materials are rolled into flat bars, which are lagged together and rolled into long bars of the section required for the part of the gun for which they are intended. These bars are then placed in a long narrow reverberatory furnace,

Fig 34

cooled and raised to a bright red heat. When ready for cooling, one end is drawn out and fired to a revolving mandril, which pulls the bar out and winds it into a coil, like rope round a capstan. Sometimes a second bar is wound round outside the first coil, in this case the mandril is made to

Fig 35

revolve in the opposite direction. The coil is next placed upright in a reverberatory furnace, and raised to a white or "welding" heat. In this state it is placed under a steam hammer, and welded till it becomes a compact hollow cylinder. On cooling it is bored and turned to the proper

Fig 36

dimensions. Two parts of the gun are made of forged iron (not coiled),—the casable screw which supports the breech end of the tube, and the hoop which carries the trunnions. The latter is either welded to the outer coil or shrunk on.

Figs 32-39 show the method of building up Woolwich

Fig 37

Building ordnance as exemplified in the 80-ton guns. The various coils are hooked together by shoulders to prevent slipping or distortion from the shock of discharge. Thus, in fig 36, shoulders are turned on the exterior of the breech-piece and inside the 1B coil, the latter is expanded by being raised to a dull red heat and slipped over the tube from the muzzle end. The expansion enables the shoulders to pass,

and on cooling they grip each other as shown, while the 1B coil contracts on and slightly compresses the part of the tube within it.

A method of strengthening and utilizing as rifled guns. Some of the old cast-iron ordnance of the service has been largely employed to supply pieces of secondary power and excellence for land fronts and for practice. It was brought forward in its present shape by Sir W. Palliser in 1863, and is now being much used in the United States' gun factories. The cast-iron block or gun is bored out to the

Fig 38

required dimensions, and a tube of coiled wrought iron is thrust into it, no shunking is here employed, but a tolerable fit is ensured by accurate turning. When fitted, the tube is secured by a collar screwed in at the muzzle, a plug of iron passes through the under side of the gun into the tube near the trunnions to prevent any shift of position. The tube is in two parts, the breech end being turned down and a second tube shrunk over it. The bottom of the bore is formed by a wrought-iron cup, which is forged and stamped into shape under a steam hammer. A screw is

Fig 39

cut on the outside of the cup and inside the end of the tube, the cup is then screwed tightly home. The tube is next severely tested by water pressure, after which the second tube is shrunk on. The whole tube is then fitted into the cast-iron casing, the greatest care being taken that the breech and bears firmly home. The gun is now ready for rifling, and, after that operation is performed, undergoes proof by firing heavy charges, which expand the tube closely against the cast-iron envelope, which then takes up the strain and affords the necessary support. The relation between the powers of the three classes of guns will be gathered from the following comparison—

Name of Gun	Weight of Gun	Weight of Projectile	Weight of Charge	Calibre	Energy of Projectile at 1000 yards	Energy of Projectile at 2000 yards
Cast-iron 60 pr., smooth bore, Palliser. 80 pr. converted from 60 pr. above.	cwt 66	lb 68	lb 18	8.13	280	120
Wrought-iron 7 in. Woolwich gun.	100	80	10	8.80	608	488
	80	116	22	7.00	1049	834

The great German gunmaker, Krupp, employs nothing steel but steel in the manufacture of his ordnance. His earlier guns were bored from solid blocks of this metal forged under heavy hammers. They were homogeneous, and therefore the exterior did not assist the interior to bear the strain of the powder gas on discharge to the extent which scientific methods of construction admit. Still the excellent quality of the material enabled the artisan to get results from these pieces which have been surpassed only by the coil guns, and by Krupp's later productions. As, however, progress was made and the ratio of power to weight increased, it was found necessary to introduce a system of building up for steel ordnance also, and Krupp adopted the principle of shrinkage to which the English guns owed so

much. The interior of the recent Gunm gun is a steel tube as in the Armstrong construction, but it is very much thicker and forms the body of the piece, instead of being chiefly used to provide a round surface for the bore. It is thicker over the powder and shot chambers, tapering towards the muzzle (fig 40). Over the thickest part, and in some guns over a considerable portion of the chase, hoops of cast steel are shrunk on,—the shrinkage being adjusted

FIG 40.—Section of Krupp Gun

to bring the strength of the outer hoops into play to support the body of the gun on discharge. The number of hoops depends on the size of the gun and the severity of the strain it has to withstand, they are usually much more numerous than the English coils, and the section of a heavy Krupp gun presents somewhat the appearance of a stone wall. It is believed that the steel is not toughened in oil, but the details of manufacture have not as yet been made public.

Steel of the excellent quality employed by Krupp is undoubtedly a stronger material than wrought iron, its present trustworthiness is, however, of late date, and it has hardly gained the general confidence accorded to wrought iron. Possibly the method of construction adopted by Krupp, continuing as it does a number of unwelded joints, seriously permits the several parts of the guns to support each other as efficiently as is the case with the magnificent forgings of the coil system, be this as it may, the heavier pieces, though made of stronger and more expensive material than the English ones, are just as heavy for their given power, proportions and ammunition being similar.

In France and Italy a combination of cast iron and steel has been introduced with a view to economy. The interior of the gun is a moderately thick steel tube as in the coil guns, over this is a thick cast-iron body, corresponding to the steel body of the Krupp guns. On the exterior are shrunk steel hoops.

Sir J. Whitworth uses his fluid-compressed steel for the manufacture of ordnance. He forces massive hoops over a central tube, and over one another by hydraulic pressure or by shrinkage.

Mr Vassener uses Firth's quable steel for his guns, which are built up somewhat in the same way as Krupp's. He also uses external coils of wrought iron in some patterns.

Systems of Loading.—The comparative advantages of breech-loading and muzzle loading for ordnance on service are fully discussed in the article GUNNERY. We have now to mention the principal modes of closing the breech, either permanently as in muzzle-loaders, or temporarily as in breech loaders. The former is comparatively a simple matter. When the whole gun, or the interior of it, is formed of cast metal, iron, bronze, or steel, the block is merely bored to the required depth, and the end left un-bored to form the breech. Should the inner part of the gun be formed of wrought material, such as coils, it becomes necessary to close the end with some device which shall render it gas-tight and strong. Several kinds of cups and plugs have been used for this purpose, the most successful of which is the cup already mentioned in the description of the converted guns. When we come to the temporary closing of the end of the bore demanded by breech-loading, a far more difficult problem presents itself. This problem

has been more or less satisfactorily solved in a great variety of ways, but it will be sufficient to examine the three principal types or systems of breech-loading employed in modern artillery. They are popularly known as the Armstrong, the Krupp, and the French systems.

The Armstrong system is the earliest of these in point of date. In it a slot is cut through the top of the breech of the gun into the tube at A (fig 41), a breech block (fig 43) loading 43), through which the vent is driven, is dropped into this system

FIG 41.—7-inch Armstrong Breech loader

slot, and is pressed firmly against the base from behind by the breech screw (fig 43), which is provided with two powerful lever handles for the purpose. Where the breech block, or vent piece, as it is usually called, presses against the lip of the bore, both surfaces are of copper, and are renewed from time to time as channels are worn through between them by the rush of the escaping powder gas. There are many guns, from 6-pounders to 7-inch, made on

FIG 42.—Breech Screw

FIG 43.—Vent Piece

this plan in the British service, and at the time of their introduction they constituted a great advance in gun construction. Experience in the field and at practice has, however, revealed many grave faults in them. No joint consisting simply of two abutting surfaces can be made so tight as to prevent the gas from escaping on the discharge of the piece, the pressure in the powder chamber is so great that a considerable expansion takes place for the moment, and permits a fan of flame to flash out. The eroding effects of gas in motion at high pressure are extraordinarily destructive, and constant necessity for repair arises from this cause. It has also been found that in rapid firing the breech screw may be too quickly forced home, ripping the vent piece before it has fallen into its proper position, the end of the bore is then not sealed, and important and perhaps dangerous accidents occur. Moreover, even with moderate sized ordnance, the vent piece becomes too heavy for convenient lifting.

In the Krupp system (fig 44), a slot is cut through both sides of the breech of the gun, in this slot, in the latest patterns, runs a cylindrical prismatic wedge, or, in other words, a wedge of D section, the round side to the rear. The flat side forms the bottom of the bore. For loading, the wedge is pulled out to the left side of the piece as far as the stop will allow it to go, the shell and cartridge are thrust up the gun from behind, the wedge is pushed in, and is pressed hard home and secured by an ingeniously contrived screw with powerful handles. As was mentioned with regard to the Armstrong system, no amount of pressing home and securing would by itself be of any avail in pre-

venting escape of gas at the breech, and a special arrangement is therefore provided for this purpose (fig 45). The end of the bore is enlarged, and into this recess thus formed fits a Broadwell ring, against which the face of the wedge abuts when forced home. The ring is so formed that it must always fit against the wedge, and be pressed firmly to it by

Fig 44 — Krupp's breech action, cylinder-pneumatic wedge

the action of the gas on firing. This is accomplished by making the recessed surface of the gun and the exterior surface of the ring portions of a sphere. In spite of the theoretical perfection of the system, and the excellence of manufacture attained, it has always been found that after a time—after firing a very variable number of rounds—gas would begin to escape, and then speedily cut a channel between the ring and the wedge. Krupp has fully recognized this, and has been successful in minimizing and localizing the injury thus caused. The gas has two ways of escape: it can pass either between the ring C and the body of the gun D, and so out to Y, or from X to Y. Several forms of Broadwell ring have been tried by Krupp, the form shown in fig 45 is now in use. When the gun is fired the gas acts on the rounded surface of the ring C, pressing it down hard against the facing plate A, and also expanding it against the body of the gun D. The tendency of the gas is also to expand the body of the gun away from the ring, and many bronze guns have been destroyed from this cause, having expanded more than the ring was able to follow. A recess is cut in the exterior of the ring, partly to give it greater spring and partly to afford a relief channel for any gas that may have forced its way in. The form of ring here shown appears to have overcome the efforts of the gas to escape in this direction.

Having stopped the gas from getting round the outside of the ring and injuring the gun, we have now to consider the results of escape from X to Y. A channel cut through here would disable ring and wedge, which, though not so bad as disabling ring and gun, would yet be productive of much inconvenience. The insertion of the steel facing plate A at once saves the wedge and localizes the injury. It allows, moreover, of the introduction of copper discs behind the plate, for the purpose of making up for wear, compression of metal of wedge, &c. Two relief channels are cut round that surface of the ring which abuts on the facing plate. Spare Broadwell rings and facing plates are supplied with the guns, should wear set in and escape of gas ensue, the defective fittings can be removed from the gun and new

Fig 45 — A, steel facing plate; B, copper discs; C, steel Broadwell ring; D, body of gun; E, wedge; X, interior of gun; Y, exterior of gun

ones inserted in a couple of minutes. Each set should last on the average for several hundred rounds.

In the French system no slot is cut in the gun (fig 46). The breech is closed by a screw plug from the rear, which swings on a hinge to the side when withdrawn. The male screw on the plug and the female screw in the gun are divided circumferentially into six parts, of which three have the threads cut away, so that the surface is alternately screw and plain cylinder. When the threads of the plug coincide with the plain parts in the gun, the plug can be moved straight in or out. When pushed in, one-sixth of a turn engages the threads, which thus give half the bearing of an ordinary screw. This is called the interrupted screw system. The plug is longer than the bore, so as to afford room for the shell and cartridge to be thrust in. The end of the bore is recessed to take a ring against which the end of the plug abuts, somewhat as in Krupp's gun, on a cup of steel is fixed on the end of the plug, which is slightly convex, the pressure of the gas drives the flat back of the cup firmly against the convex surface, bending out the lips, which are at the same time pressed against the sides of the gun by the gas. This method has been lately introduced by the Elswick Company.

Fig 46 — French breech action, interrupted screw

It is difficult to award superiority to the Krupp or the French system. Each appears to possess some little advantage over the other, and both have attained great success. The Krupp system has undergone the more thorough testing in the field, and has the merit of allowing the parts which become damaged by the escape of gas to be replaced with greater ease and quickness. The French system, on the other hand, takes up less of the gun, so that in a piece of given length the bore may be upwards of one calibre longer than with Krupp's. In the French system, also, the breech-fittings are less exposed to damage by the enemy's fire, being behind the gun instead of at the side.

DESTROYING—A gun, like all other machines, must be Gun designed to fulfil certain definite conditions. Its projectile signature may be required to piece a given thickness of armour at a given distance, or weight of piece may be the limit, and it may be wished to throw the most powerful shell or shrapnel to a given distance with a given elevation, consistent with that limit. To work out problems of this nature, it is all important to possess an accurate knowledge of the action of the charge made the bore. By means of the Noble chronoscope and the crusher gauge (see GUNNERY), this knowledge is obtained, and we shall now explain how the indications of these instruments are employed to assist in determining the proportions of ordnance.

Gunpowder is not properly so much an explosive as a substance burning and giving off gas with great rapidity. It differs in this respect a marked contrast to gun-cotton, dynamite, and other true explosives. If one of these agents be detonated, the detonation is immediately carried through the mass, whatever its size, and the whole at once turns into gas. Gunpowder, on the other hand, as far as is known at present, cannot be detonated, but simply evolves its gas by burning in layers from the outside to the inside. Thus a large grain will take longer to burn up and become

gas. Gunpowder, on the other hand, as far as is known at present, cannot be detonated, but simply evolves its gas by burning in layers from the outside to the inside. Thus a large grain will take longer to burn up and become

Pressure

powder
gas

entirely converted into gas than a small one will, hence the effect of enlarging the grains is to render the action of the charge less violent, the composition of the powder being the same in all gun-charges. The projectile is driven out of the bore by the pressure of the gas on its base,—that is, on an area which varies with the square of the calibre. The weight of projectiles of small form varies with the cube of the calibre. Hence the larger the gun the heavier will be the column of metal or projectile driven by each square inch of its base, and the greater must be either the pressure applied, or the time of its application, if a given velocity is to be attained. The great object of the gunmaker is to obtain the highest possible ratio of muzzle velocity to breech pressure. His ideal would be a charge so arranged that a pressure equal to the amount the gun is constructed to bear should be uniformly maintained till the shot has left the muzzle. Science is still a long way from this, but has done a good deal towards it in the last few years. A charge of gunpowder, composed of service ingredients in service proportions, exploded in a closed vessel at a density of 1.00 (equal to that of water), sets up a pressure of 13 tons per square inch, at a density of 0.75, of 23.2 tons, at 0.50, of 11.8 tons. Supposing a gun cartridge to be rammed home to the density of water, and entirely converted into gas before the projectile begins to move, the pressure in the bore would rise to 13 tons per square inch at the breech, and fall towards the muzzle, as the travel of the shot afforded increasing room for expansion behind it. The column of metal to be moved, even in the heaviest projectiles yet known, is only a few pounds to the square inch of base, while the maximum pressure of the powder gas is measured in tons; it is clear therefore that the shot must get under way at some point antecedent to the setting up of the maximum pressure. In a breech-loader, where the projectile has to be forced through a bore slightly less than its greatest diameter, it will be detained longer than in a muzzle-loader, where it moves freely away, but the difference is unimportant as regards the present argument. The result of the shot's early motion is that space is at once given for expansion, and the normal 13 tons is never reached. Before these matters were fully understood, badly-proportioned charges of violent powder were found sometimes to set up what are known to artillerymen as "wave pressures," which were dynamical in character, being caused by rushes of gas

from one end of the charge to the other, so that the gauges indicated far higher pressures at the ends of the powder chamber than in the centre. This has now been overcome, and a great increase of both power and safety has been obtained. Several important improvements have been made of late years, the principal ones are three in number—(1) a great stride was made in the manufacture of powder when pebbles, prisms, and 1½ inch cubes were introduced, (2) the discovery of the beneficial effect of "clambering," that is, of boring out the powder chamber to a greater diameter than that of the rest of the bore, (3) the method of "air spacing" the cartridge, so that a certain air space weight of powder should have a certain definite space allotted to it, irrespective of the actual volume of the powder grains. Thus in the 80 ton gun powder cubes of 1½ in. edge are used, having an absolute density a little over 1.75, or about 15.7 cubic inches to the pound. If these grains were rammed tightly home in a silk cloth bag, the space occupied behind the shot would be 24.6 cubic inches per pound, as actually used, an air-space over, and within the cartridge is left, so that the space behind the shot amounts to 34 cubic inches per pound. This density would set up a pressure in a closed vessel of 20.6 tons per square inch, but the relief afforded by the shot's motion reduces it to about 19 tons per square inch. The effect of clambering out the end of chamber the bore where the powder lies is practically to permit a small gun to consume effectively the charge of a larger gun. The cartridge is shortened, and the mechanical conditions of burning are greatly improved, so that, with large charges, higher velocity with lower pressure is obtained from a chambered than from an unchambered gun. The above information is derived from the indications of the crusher gauge, which registers the pressure of the gas at various parts of the bore. The chronoscope measures the rate at which the projectile acquires velocity during its travel from the breech to the muzzle. Knowing the increment of velocity at any point, we can calculate the amount of pressure required to produce this increment, and thus confirmation is obtained of the accuracy of the records obtained by the crusher gauge. The following table gives the increase obtained at successive stages in the development of the power of the 80 ton gun, which was first under-bored for experiment, and gradually brought to its present dimensions—

Table showing Experiments with 80 ton Gun Powder, Series P₂ (1½ inch cubes)

Calibre	Diam. of Chamber	Weight of Charge	Duration of Charge	Weight of Projectile	Max. † Mild prismatic powder (German)

It will be observed that each improvement has tended to facility of consumption of increased charges, so that, while the pressures are diminished, the penetrating power of the projectile is augmented, a heavier and more destructive shell being driven through thicker armour.

The manner in which the various principles, of which an explanation has been above attempted, are practically applied is laborious and complicated; the conditions are often conflicting, and the ultimate dimensions of a piece of ordnance is commonly a compromise. A couple of simple examples will illustrate the *modus operandi*. Suppose that it is required

to design a gun which shall not exceed a given length, but shall throw a projectile capable of piercing a given thickness of non-ferrous metal at a given range. There are several formulae of a more or less empirical nature for calculating the penetrating power of a projectile moving with a known velocity. Penetration is by some regarded as a punching action, by some as a wedging action, probably it is a compound of the two. Recent experiments carried on with the very high velocities of about 3000 f/s have thrown some doubt on the soundness of any of the formulae. That generally used in England is as follows—

Let W = weight of projectile in tons,
 r = radius in inches
 v = velocity of do. in feet per second,
 $E = \frac{Wv^2}{2}$ = energy of do. in foot tons,
 $t = \frac{2r}{v}$ = thickness of plate perforated in inches,
 then $\frac{E}{2rt} = 253d^2$

This formula tells the gun-designer what energy is necessary to overcome the resistance of the plate. Guided by experience, he assumes for the moment a striking velocity, the other component of the energy, the weight of the projectile, is then directly arrived at. The proportions of amount piercing shell are the same for all guns, so that the weight guides the dimensions, and the calibre of the gun follows. Should this appear to be in no way unsuitable to the length already laid down in the conditions, the gun-designer calculates the loss of velocity in the given range and from the striking velocity deduces the muzzle velocity and the muzzle energy. The excellent labours (*Researches on Explosives*) of Captain A. Noble, F.R.S., of Elswick, and Professor Abel, F.R.S., have shown how to calculate the amount of work done by a pound of powder for every volume of expansion its gas undergoes, the results of many careful experiments and much intricate calculation are embodied in the accompanying table, which

affords the means of determining the total work performed by any charge in any gun. A certain portion of this work is expended in heating the gun and projectile, in giving rotation, and so forth, the remainder appears as the energy of translation of the shot on leaving the muzzle. Large guns realize a greater proportion of the total work than small ones, the gunmaker knows very approximately by experience what percentage may be expected from certain classes of ordnance with certain descriptions of powder. Roughly the factor of effect may be put within the following limits:—for mountain guns, 45 to 50 per cent; field guns, 60 to 65 per cent; medium guns, 70 to 80 per cent; heavy guns, 85 to 88 per cent. The method of calculation will be best understood from an example. Suppose a charge of 425 lb of P_n powder is to be fired from the 80 ton gun chambered to 18 inches diameter, the projectile weighs 1700 lb, and the space behind it is 14,450 cubic inches

The whole content of the bore is 60,400 cubic inches, and the volume of the charge is (425×27.7) 11,773 cubic inches, the number of expansions therewith is 5.13, the action of the table shows that powder gas expanding to this extent from a density equal to that of water can perform work amounting to 92.4 foot-tons per lb. Since, however, the charge burns up and has to fill (425×34) 14,450 cubic inches before doing work, the energy due to this extent of expansion (1.227) is lost, and 177 foot-tons per lb must be deducted, leaving $(92.4 - 17.7)$ 74.7 foot tons per lb as the total work the charge is capable of performing under these conditions. It is known from the preliminary tests of the powder that in the 80-ton gun between 92 and 96 per cent of the total work will be realized. Hence the energy of the projectile will lie between 29,210 and 30,165 foot tons, says its muzzle velocity between 1581 and 1600 f s. A reference to the table on p. 292 will show that the result actually arrived at lies nearly midway between these limits.

In this manner the charge required to impart the necessary energy to a shot of given weight in a given length of bore, and, conversely, the length of bore which will contain the requisite number of expansions of a given charge, are easily found, hence the charge required to produce the necessary energy is readily found, the air space and the dimensions of the powder chamber follow, and the inside of the gun is settled. The gun designer now has to put walls round his bore. Guided by the knowledge previously mentioned as derived from the culverin gauge and the chronoscope, he lays down the pressures at each point of the interior, and calculates the amount and strength of the metal to be used, according to the special system of construction employed, and thus the exterior of the gun is settled. To give another instance—let it be required to construct the most powerful howitzer that can be made for the siege train. The conditions are given thus— α —cal of piece only must not exceed 20 feet per second, weight of piece must not exceed 70 cwt, limiting purposes are to breach at 1500 yards, with not more than 5° elevation, and to bombard at 5000 yards, with not more than 35° elevation. A piece weighing 70 cwt and running back at 20 f s velocity gives 156,800 units of momentum (in pounds and foot-seconds), the initial momentum of the gun in recoiling is practically equal to the momentum of the shot on leaving the muzzle. Hence the shell must have 156,800 units of momentum, which may be composed of high velocity and light weight, or low velocity and heavy weight. For breaching purposes, accuracy and penetration are essential qualities, a shell varying in length from two and a half to three times its diameter will be suitable for the purpose. We have now a neat problem in ballistics, viz., To find the calibre of a shell of the proper length, of such a weight that, with the muzzle velocity required, to give a range of 1500 yards at 5° elevation, the muzzle momentum shall be 156,800 units. This problem is readily solved by the methods indicated in the article GUNNERY, and it is found that a shell 80 in in diameter, weighing 170 lb, and having a muzzle velocity of 940 f s, will be slightly on the safe side of the limits. Proceeding in a similar manner, a shell 80 in in diameter, weighing 230 lb, starting with a velocity of 875 f s, satisfies the conditions of bombardment. The calibre being thus settled, the proportions of the piece remain to be worked out. As there is no difficulty in obtaining a velocity so low as 940 f s with a small charge and low pressure, the length of the bore and the disposition of the metal can be adjusted to suit, not only the strain of discharge, but the conditions of service. In the gun now under consideration, the bore is made as long as possible, and the weight of metal thrown as far forward as possible consistently with preserving due strength at the breech. The reasons for this are threefold.—first, the longer

the base the less is the breech pressure required to produce a given muzzle velocity, and the less is the maximum strain thrown upon the studs, gas, block, or other rotating agent; next, the more level and the general disposition of the metal, the farther from the breech will be the centre of gravity, and consequently the trunnions—a position which favours steady shooting; and absence of jump, thirdly, a siege howitzer, being always fixed under cover, is little exposed except near the muzzle, which should therefore be made as strong as possible to avoid injury from anything less than a direct hit by mortar shell.

Rifling.—Spherical projectiles fired from smooth-bored guns seldom or never pursue the mean trajectory. The centre of the ball's figure will rarely coincide exactly with the centre of gravity, and the pressure of the air during flight will therefore with unequal effect on different parts of the surface. This inequality will be increased by accidental imperfection, or roughness. The difference between the diameter of the bore and that of the projectile is termed "windage," when this is considerable, it is a principal cause of error in shooting, as the ball rebounds from side to side against the walls of the piece as it is driven along, its actual direction of departure depending on the effect of the last bump before it leaves the muzzle. Accuracy of manufacture may greatly mitigate these errors, but will never entirely remove them, it is therefore found necessary to cause the projectile to rotate rapidly round its axis coincident with the axis of the gun, by this means the inequalities in the action of the pressure of the air, due to the imperfections above mentioned, take effect in all directions in turn as the projectile rotates, and hence neutralize each other. Extending this principle, the stability imparted to a shot by its moment of rotation is such that elongated projectiles can be employed and driven point first at high speed through the air. The course of the projectile from the time of its leaving the muzzle to the end of its flight belongs to GUNNERY (*q.v.*) Here we have to consider the modes in which the interior of the gun is made to impart rotation to the projectile. Rotation is usually expressed in angular velocity, a shot is said, in popular language, to make so many turns per second. Mathematically, the unit of angular velocity consists of rotation through the unit of circular measure in one second, the unit of circular measure is the arc subtended by an arc equal to radius, viz., $57^{\circ} 17' 41'' 48''$. If we call this angle α , a complete rotation will be expressed by $2\pi/\alpha$. In considering the energy stored up in a shot's rotation, or, what is the same thing, the work done in producing that rotation, the weight of the projectile W , and its radius of gyration ρ , must be taken into account. The energy of a travelling

FIGURE
47
Plan of
rifling

body is $\frac{Wv^2}{2g}$, the weight of a rotating one is supposed to be concentrated at the end of the radius of gyration; then if Ω be the angular velocity, the velocity of a travelling body will correspond with $\rho\Omega$ in a rotating one, and the energy of rotation will be expressed by $\frac{W\rho^2\Omega^2}{2g}$. The proportions of service projectiles differ for different guns, the thicknesses of sides and base and the shape of head varying, but roughly for common shell the value of ρ may be taken as $0.40d$ (d =diameter), for Palliser projectiles as $0.38d$, and for shrapnel as $0.36d$. For artillery purposes a projectile is said to turn once in so many calibres, that is, to make one complete revolution in travelling a distance equal to so many times the diameter of the bore. Supposing a given length of groove in the bore to make a known angle with a line parallel to the axis of the gun, determining the arc through which the surface of the shot must turn while advancing the length of the groove, it is evident that the angular velocity attained by the shot will entirely depend

on the velocity of translation or forward movement. Again, the greater the diameter of the bore the less will be the proportion borne by the arc traced through to the whole circumference, consequently the bigger the gun the less the angular velocity of the projectile, if the angle of rifling and the velocity of translation remain constant, the velocity of rotation of a point on the surface will, under these conditions, always be uniform. It is generally considered that with studded muzzle loading service projectiles, having a length equal to about 24 to 3 times their diameter, the velocity of rotation of a surface point of about 110 f/s is sufficient to keep them steady, allowing for loss of spin by atmospheric friction up to any probable range. Supposing the interior of the gun to be opened out and laid flat the groove (of a uniform twist) will be straight, and since the shot guided by it makes a complete revolution in 15 calibres, the angle made by the groove with a line parallel to the gun's axis may be expressed by $\tan \frac{\pi}{15n}$. In designing the

piece, the muzzle velocity is determined on, and also the velocity of rotation to be communicated to the projectile, the combination of the two fixes the final angle of the groove. Now it is easy to see that the spin of the shot on leaving the bore depends only on the conditions immediately preceding. The rate at which the work of giving rotation is done during the travel of the projectile from breech to muzzle is an entirely different question. If a shot be rotating, its tendency is, meeting friction made for the moment, to continue to rotate with the same velocity. No work is done in keeping up this rate of rotation, but work would be done in accelerating or retarding it. Thus in apportioning the work done on the shot in giving rotation at different parts of the bore, we have to consider, not the actual angular velocity, but the increments of angular velocity. The work then can be distributed at pleasure over the whole length of the groove, by varying the angle it makes with a line parallel to the gun's axis, as it runs along the bore. Supposing, as before, the interior surface of the gun to be opened out and laid flat, then OU (fig 47) will represent a groove having a uniform twist, that is

Fig 47

making a constant angle with a line OM parallel to the axis of the piece. O denotes the commencement of the rifling at the breech and of the bore, UFM the muzzle. Guns are rifled with any number of grooves exceeding two, but it is not necessary to consider more than one. With the groove OU, every increment of angular velocity imparted to the shot is due to an increment in the velocity of translation, and therefore the pressure between the sides of the grooves, and the studs, gas check, lead coating, or whatever fitting on the shot is employed for the purpose, bears a constant relation to the pressure of the powder gas on the base of the shot during its forward travel. The table given below shows the result of this with great clearness. In order to mitigate the unevenness of strain, because we had to the increasing twist, and a curved groove was employed which, when developed as in fig 47, forms the parabola OP, beginning at the point O, parallel to OM, and terminating at F, parallel to OU. The equation to OU is $x = py$, that to OP is $x^2 = py$. Since OP is a parabola having its vertex at O, and since the tangent at P is parallel to OU therefore

UP = PM, which shows that the shot, though rotating in either case with equal angular velocity on leaving the muzzle, has, up to that moment, with the parabolic twist turned through an angle half as great as would be the case with the uniform twist. The table below exemplifies the principle on which curves of rifling are, or should be, constructed. The first three columns speak for themselves, the fourth is arrived at by multiplying the area of the shot's base by the gas pressure per square inch recorded on the gauges, and given in the fifth column. Columns 6 and 7 are worked out from formulae due to Captain Noble of Elswick, in

column 6 the pressures due to a uniform twist are given. Pressures. It will be seen that they bear a constant proportion to the on pressures of the gas recorded in columns 4 and 5, and that the maximum rises to a considerable height soon after the shot has begun to move, while at the muzzle little work is done. In column 7 the calculations are made to suit a curve consisting of a portion of a parabola, starting from the vertex where the groove is parallel to the axis of the piece, and rising to the required twist at one foot from the muzzle, thence proceeding uniformly. In this curve the maximum strain is greatly reduced, the pressure gradually

Table showing Pressures of Gases on Studs in the 88 ton Gun, with various Curves of Rifling. Charge, 130 lb. Cubical Foot of 1.25 inch edge. Projectile, 800 lb. Calibre, 12.5 inches.

rising with the increase of twist. The figures are derived from another formula worked out by Captain Noble. Column 8 shows the pressures required to give the necessary rotation when the curve of groove is a semicubical parabola, having for equation $x^2 = 2y$. In the instance chosen, the early part of the curve is rejected, and it starts from 1 turn in 200 cal., arriving at the required twist at a foot from the muzzle as before. The figures are derived from a calculation worked out on the principle devised by Captain Noble. Here the maximum is yet further reduced, and some approach to uniformity of strain is made. The diagram in Plate IV shows the pressures graphically.

Let R = rotation pressure between studs and grooves,
G = gas pressure on base of shot,
 μ = coefficient of friction,
 h = pitch of rifling,
 λ = tan of angle made by groove with plane traverse to axis;
 ϕ = angle turned through by shot,
 θ = angle made by groove with line parallel to axis,
 ρ = radius of gyration,
 s = travel of shot along bore,
 v = velocity of shot,
M = mass of shot = $\frac{W}{g}$,
 r = radius of shot.

Then in a uniform twist ($\phi = \lambda r \phi$)

$$R = \frac{2\pi\rho^2(1 + \mu^2)^3}{\lambda^2(h - \mu) + 2\pi\rho^2(\mu^2 + 1)} G,$$

in a parabolic twist ($\phi = \lambda r^2 \phi$)

$$R = \frac{2\pi\rho^2(4\mu^2 + \mu^2)^3}{\lambda^2(h - 2\mu) + 2\pi\rho^2(3\mu + \mu^2)} G,$$

in a semicubical twist ($\phi^2 = \lambda r \phi$)

$$R = \frac{3\rho^2 \left(G \lambda / s + \frac{4\mu^2}{2\pi h} \right) (8s + 4\mu^2)^3}{h^2(4s - 6\mu/\lambda) + 3\rho^2\lambda(s/\lambda + 2\mu)}$$

Lieut. Youngblood, R.N., gives the following formula, which is applicable to curves of any equation, and will be found much handier than the above by those familiar with differential calculus:—

$$R = \frac{\rho^2(G \tan \theta + \frac{2\pi\mu^2}{\lambda^2} \frac{v^2}{s})}{\lambda^2(1 + \tan^2 \theta) - \mu \tan \theta (1 - \mu)} \sqrt{1 + \mu^2}$$

A radical difference exists between the rifling of muzzle-loaders and that usually employed for breech-loaders. When the projectile has to be pushed down the gun from the front, it must be smaller than the bore, when it is thrust home from behind, it may be rather larger than the bore. Hence the earlier muzzle-loading shells were provided with ribs or studs which fitted in the grooves, and guided the projectile in its rotatory course, while the earlier breech-loading shells were coated with lead, into which the lands of the bore bit sharply as the powder gas forced the projectile between them. All rifled ordnance were formerly rifled with a uniform twist, indeed, it is clear that where ribs are cast or fixed on the projectile, or where they are formed in the soft envelope by the first action of the grooves, no alteration in the angle of rifling is possible, since the ribs can only make a constant angle with a line parallel to the axis of the piece, and cannot fit a groove making a varying angle with it. The smaller and earlier muzzle-loading rifled projectiles were fitted with two rows of studs, front and rear, and equal in size, so that a front and rear stud travelled in each groove, and practically constituted the ends of a rib. As the guns grew, it was found that the great strain of giving rotation at starting fire frequently forced the bronze studs out of the recesses machined for them in the sides of the shells, and scooped away the driving edges of the grooves even when the gun lining was of steel. The shell might have been cast with ribs on them, but certain difficulties of manufacture stood in the way, and the excessive strain would still have existed though its effects might have been mitigated. The increasing twist was therefore devised, and the rows of studs increased in number from two to three in the larger natures of projectiles. Three studs are allotted to each

groove, the rear one is the largest, the front one the smallest.

They are so placed that the line of their leading sides is parallel to the axis made by the groove at the breach, while the line of their driving edges is parallel to the angle made by the groove at the muzzle. In Plate IV fig. 1 shows their position when the shell is home, and also when about to leave the bore. Thus, theoretically, the middle and leading stud should never come into play till the last moment, and the rear stud should do all the work of rotation. Practically, however, the rear stud, being of bronze, wears down against the edge of the hard groove, the centre stud obtains a bearing, the wear continues, and the leading stud takes up its share of duty, so that all three really act during the passage of the projectile through the bore. This method of employing the increasing twist necessitates wide grooves, and is unsuitable for small guns. A different plan therefore was devised to meet this case. Two rows of studs, front and rear, were so arranged that each ran in a groove of its own. The curve of the grooves belonging to the rear stud began at 0°, and reached the final angle at a distance from the muzzle equal to the distance between the front and rear rows, after which it proceeded in a straight line. The curve of the grooves belonging to the front studs began at 0°, at a distance in front of the commencement of the other grooves equal to the distance between the rows, and reached its final angle at the muzzle. Thus the two curves were alike, but one was always a constant distance in front of the other, and every stud acted through the entire length. Fig. 2 in Plate IV shows the position of the studs when the shot is home, and also when it is about to leave the bore.

Sind

Gas

check

Muzzle loading itself had reached this stage of progress at a time when the great wear caused by the rush of gas over the shot necessitated the adoption of some method of sealing the escape. After many trials, it was found that a flanged copper disc fitted on to the base of the projectile would expand under the first pressure of the gas, and cut off the windage completely. This saved the wear of the guns, and added to their power. It was found, moreover, that the fingers of these "gas checks" expanded in the grooves, and being firmly attached to the shell afforded an additional means of giving rotation. The next step was to remove the studs altogether, using a smooth projectile, and substituting many small grooves for few large ones. This method of giving rotation has been adopted in all recently-designed pieces, and appears likely to give entire satisfaction. When muzzle-loading guns were first rifled, many attempts were made to give rotation by expanding projectiles, but they proved unsuccessful, because at that time the increasing twist was not known, and the action of a violent powder and the uniform twist was that the rotator had to expand into the grooves, and at the same instant to communicate a rapid spin to the shell. It was unable to combine these operations, and the projections driven on by the gas could never settle to their work, being constantly cut down by the edges of the grooves. The result was that the shell "stripped," and left the bore without regular rotation. In the case of the twist which begins at 0°, the projections have time to expand comfortably, and adapt themselves to the shape of the grooves before they are called on to perform the work of rotation. On the other hand, since the gas presses out the flanges against the bore and into the grooves, and affords them support in this position, it is desirable that its pressure should correspond with their pressure on the driving edges of the grooves. This would be exactly met by the uniform twist, but that is inadmissible for the reason just given. The parabola, on the other hand, throws the principal rotating strain forward towards the muzzle, where the gas pressure is least (Plate IV). The case is practically met by the semi-cubical parabola, which is the curve adopted

in the 80 ton gun. While progress was thus being made in the rifling of muzzle loaders, the rival system had not remained inactive, the use of lead coating had been found to involve a loss of power in the projectile as regarded both the amount of bursting charge or bullets carried, and the penetration into armour, on to the surface of which the lead flew forward in a splash, when the shell struck. Moreover, the lead envelope would not lend itself to the exigencies of the increasing twist. To meet these difficulties, two undercut rings were machined round the smooth projectile, one near the base, the other near the shoulder. Into these slots were pressed stout copper wires, the rear one bringing up the diameter of the shell beyond that of the bore, and the other the rifling when forced through the piece on discharge, the front one just fitting the lands, but not entering the grooves, so as to rotate irrespective of them, and thus keep the fore part of the shot steady. Projectiles thus fitted are more effective than the lead coated ones, and are adapted to any twist of rifling. The latest breech-loaders made by the Elswick Company use the new arrangement described above for muzzle loaders—the smooth shell with a gas check on the base. This appears to be the best form of projectile, and has the advantage of suiting either system. A few words on the section of groove best suited to various purposes will conclude the subject of rifling. The rotation is imposed on the projectile by a force acting tangentially to the surface. This principle would be rendered more effective by making the section of the shell to resemble a cog-wheel, the grooves and lands of the gun being bent to fit. With muzzle-loading systems where windage has been necessary, the sides of the projections on the projectile, and of the grooves in the bore, have been sloped to enable the projections to run up the sides of the grooves, and so distribute the windage equally all round. The extreme form of this principle is Lancaster's oval bore, the section of which departs but slightly from a circle. All attempts at "centring" the projectile by sloping the bearings tend Cent to convert it into a wedge, which expands that part of the nose fore resolved radially in a crushing action on the shell, and a ending action on the gun. The slope may, however, be made of such a degree as to cause the projectile to centre fairly without exercising any important effect on the bore. In breech-loading systems, where the lands bite into the rotator, the driving edge strikes the projectile in, or nearly in, the prolongation of the radius, care being taken that the points of action are as many as possible consistently with leaving enough material between to stand the wear and the strain. Where gas checks expand in the grooves, these should be broad and flat, so that a complete fit and a strong projection should result. The driving edges should here also form a prolongation of the radius of the projectile.

Conclusion.—What may be the future of firearms it is Concha impossible to predict, but it seems probable that the limit sum of power will be found to lie in the recoil. For shoulder guns, methods of withstanding increased velocities may be devised, but the weight of springs, pads, &c., will prevent the soldier or the sportsman from carrying this principle very far. For ordnance, the field artillery appeal even now to be very near the limit of what power can be gained consistently with high mobility. Siege and heavy guns will no doubt gain by the increased application of hydraulics, but it is difficult to see how progress can go much further except in the matter of size, to which there appears to be practically no limit. Accuracy may be improved by more perfect methods of range finding, but, as regards the actual shooting of the guns, it is already an advance of the difficulties of atmospheric irregularity, which affects the smaller projectiles greatly. The reader who wishes to study the subject closely and technically is referred to the list of works given at the end of the article on GUNNERY. (S M)

GUNNERY

IN its early days this science might have been simply defined as the art of determining the motions of projectiles discharged from pieces of ordnance, in its present state it includes also the employment of projectiles specially adapted to the purpose in view, and the manipulation of artillery so as to enable the projectiles to produce the maximum effect.

Theory of Gunnery—Instruments of great precision, mechanical construction of much accuracy, and a considerable knowledge of the higher mathematics are necessary to obtain and make use of trustworthy data for the establishment of sound principles on which to base the theory of gunnery. It is therefore not surprising that, owing to the early discovery of gunpowder, the art was long practised in a rude manner, without any attempt being made to reduce it to a science. Thus, though firearms appear to have been in use from the early part of the 14th century, little of value was understood of the laws regulating the flight of projectiles till the time of Nicholas Tartaglia, who published a treatise on the subject at Venice in 1537. About sixty years before that date, Leonardo da Vinci had enumerated some of the mathematical principles of trajectories in a manner which shows him to have possessed far more insight than any of his contemporaries, but he did not pursue the inquiry, and Tartaglia may be regarded as the father of ballistics. He was a man of great talent and ingenuity, but unfortunately had no opportunities of observing artillery practice, he was unable, therefore, to bring his calculations and speculations to the test of fact, and failed to carry conviction to the minds of the philosophers of the age. Before his time it had been generally believed that a ball on leaving the bore of a gun proceeded for some distance in a straight path,—a fallacy which lurks in the phrase "point-blank," not yet expunged from popular speech. He saw, however, that "a piece of artillery cannot shoot one pace in a right line," and propounded the axiom that "the more swift a pellet doth fire, the less crooked is his range,"—a truth expressed at the present day by the statement that a high velocity gives a flat trajectory. This eminent philosopher claimed the invention of the gunner's quadrant, he took into account in his calculations the resistance of the air, but placed the angle of elevation at which the maximum range would be obtained at 45°, which would only be the case in *vacuo*. Galileo was the next mathematician of note who investigated the subject. In his *Dialogues on Motion*, published in 1638, he recognized fully the resistance of the air, and pushed on the inquiry in the direction indicated by Tartaglia. It was not, however, till Newton's time that a substantial basis was laid down for a true theory of gunnery. The grand discovery of the law of gravitation revealed the hitherto unguessed secret of the projectile's fall to earth. The great improvements in mathematical methods of analysis invented by him rendered possible solutions of previously impracticable problems, while the splendour of his achievements in natural science stimulated philosophers of all countries. Towards the end of the 17th century he investigated the trajectory of a projectile on the supposition that the resistance of the air varied as the first power of the velocity. Bernoulli in 1718 gave a solution of the problem, on the supposition that the resistance varied as any given power of the velocity. This solution was, however, left in such a complicated state that no practical use can be made of it. No further progress was made till Benjamin Robins in 1742 published his *New Principles of Gunnery*, in which he furnishes a notable example of the manner in which theory should be

wedded to practice, and hypothesis to experiment. Had Robins been in the possession of accurate instruments he would probably have arrived at results of considerable correctness. He invented the ballistic pendulum, and was the first to ascertain experimentally with any degree of correctness the velocities of projectiles on leaving a gun. A "triangle" or gun appurtenant a pendulum of iron having a massive wooden bob, to the bob was fixed a steel ribbon which passed through a steel clamp set to the desired pressure. A bullet fired into the wooden bob caused the pendulum to swing, the length of the arc described was recorded by the steel ribbon, the weight of the bullet and the conditions of oscillation of the pendulum being known, the velocity of the bullet could be calculated from the length of the arc. The weight of Robins's first pendulum was 56 lb, and it was therefore only suited for small arms. It could measure the velocity at only one point each round, and therefore, to ascertain the velocity lost by a ball in passing through the air, it was necessary to fire a series of rounds at one distance, and afterwards a similar series of rounds at another distance. Velocities of 1700 feet per second were measured, and the loss of velocity due to the resistance of the air, up to a distance of 250 feet from the muzzle, was approximately ascertained. Robins discovered that the resistance of the air was greatly increased as soon as the ball travelled faster than sound, and attributed it to the creation of a vacuum behind the shot, into which the air could not rush with speed greater than that of sound. Count Rumford in 1781 made use of the recoil to measure the velocities of bullets, on the principle that the momentum of the bullet forward was equal to the momentum of the gun backward. To carry this out, the gun was suspended as a pendulum, and the length of the arc it described on firing measured. By firing a bullet from a gun thus suspended into the ballistic pendulum, two independent records were obtained, and it would have been easy to calculate the loss of velocity from the muzzle to any range at which the pendulum could be hit, by the combination. The roughness of the methods unfortunately did not permit completely satisfactory results. Dr Hutton next took up the inquiry, and increased the weight of the pendulum and the bullets. No very great advance, however, seems to have been made till 1840, when experiments on the resistance of the air to the motion of spherical shot were carried on at Metz by the French Government. MM. Piobert, Morin, and Didion were the chief experimenters. They raised the weight of the receiving pendulum to nearly 6 tons, and fired into it 50-pound balls at a range of 330 feet. The information now obtained spread over a much wider field than that traversed by Robins. It was even found possible to construct the trajectories of projectiles with some approach to truth, and empirical formulae were laid down by which ranges and times of flight could be approximately calculated. It was not, however, till the introduction of electricity as a means of determining the velocities of projectiles that accurate knowledge of the resistance of the air was obtained. In 1840 Professor Wheatstone invented an instrument for this purpose, called the electromagnetic chronoscope. He has had many successors, whose productions exhibit a great amount of ingenuity, those Electric from which the most valuable results have been obtained, and which are in use at the present moment, are the Bashforth chronograph, the Noble chronoscope, the Le Boulenger chronograph, and the Watkin chronograph. The general principle on which these four instruments are designed is that a projectile after leaving the gun shall

sever a fine wire stretched across a screen, thus breaking an electric current, and causing a record to be made by the

FIG. 1.—Bashforth Chronograph.
instrument at the moment. The Le Boulenger is connected with two wire screens only, the others with several. As

two records are necessary to obtain a velocity, reading the time taken by the shot to pass between two screens, the number of points of a shot's flight at which an instrument is capable of indicating the velocity is one less than the number of screens employed. The chronograph invented by the Rev. F. Bashforth, late professor of mathematics to the Advanced Class of the Royal Artillery, is shown in fig. 1.

A is a fly-wheel, which, in revolving, carries with it K, a cylinder Bashforth covered with paper specially prepared to receive the records of the chronograph. B is a toothed wheel which turns the drum M graph, and unwinds the string CD, thus allowing the platform S to descend slowly down the slide L. K, B, M are two electromagnets, whose keepers are supported by the frames A, D; F, F' are the ends of springs which act against the attraction of the electromagnets. There are two distinct currents—one through the screens and L, the other through the clock and M. When these are interrupted, one by the shot cutting a screen, or the other by the clock beating seconds, so that the magnetism is destroyed, the spring F or F' carries back its keeper, which, by means of the arm a or a', gives a blow to the lever b or b', causing the marker m or m' to depart from the uniform spiral it has been describing—a spiral consisting of a double line running round the cylinder. The apparatus is adjusted so that the platform L, and consequently the markers m, m', descend about 4 inch for each revolution of the cylinder; the fols of the spiral are thus 1 inch apart. The cylinder is made to revolve with considerable rapidity, so that the intervals between the successive clock marks indicating seconds measure from 20 to 25 inches; hence the screen marks indicating the moment of the severance of the wire by the shot can be allotted to their proper value in seconds with great accuracy. The screens are so contrived that the current, interrupted by the passage of the shot through one, is completed again before the next is reached. To accomplish this, the cutting of the wire is made to release a spring which makes a fresh contact; thus any number of screens can be used and a corresponding number of records obtained.

The chronoscope invented by Captain Noble of Elswick, Noble late Royal Artillery (figs. 2, 3, 4), is constructed to furnish almost eight or more records, according to the number of discs, scope, and is so excellently adapted for the measurement of exceedingly minute portions of time that it is usually employed to ascertain the velocity acquired by the shot in moving from a state of rest inside the gun at different parts of the bore. It is thus intimately connected with gunmaking,

FIGS. 2, 3, 4.—Noble Chronoscope.

but, having the same character as other velocity instruments, is described here. The screens used for recording the flight of the shot through the air are now discarded, and the

Fig. 5.—Cutting plug, knife down. Fig. 6.—Cutting plug, knife up. "cutting plugs," shown in figs. 5, 6, 7, are substituted for them. In figs. 5 and 6 B is the bore, and A a flat-headed shot or cylinder passing along it in the direction of the arrow. The plugs are screwed into the sides of the gun, as in fig. 7, which gives an end view of the bore. As the shot passes, its foremost edge pushes up the knife D, cutting the wire G, which passes in at one side of the plug C, then through a hole in the knife D, and out again at the other side of the plug. The ends of this wire are connected with the main wires leading to the instrument, and the knife D, in cutting it, interrupts the current. Fig. 4 shows a 10-inch gun pierced to receive cutting plugs in eighteen places. The main wires run from a plug to the primary of a Ruhmkorff coil, fig. 2, near the instrument, with which the secondary communicates. Figs. 2 and 3 show the instrument in plan and elevation.

Fig. 7.—Cutting plug, ready for firing.

A, A, are disks, 36 inches in circumference, fixed on a horizontal shaft S. This shaft is caused to rotate, so that the edge of the disks travel about 1100 inches per second, by a series of toothed wheels F, F, gearing as shown, and worked into rapid motion by the handle C. This motion is kept up regularly by the descent of the weight B acting on the lightest shaft, the speed of which is multiplied 300 times at the shaft S. At V is a vernier, reading a graduated circle, which is fixed on the shaft S. The edges of the disks are covered with a coating of lampblack. One of the secondary wires G is brought from the coil, and placed in communication with the revolving disk; the other secondary wire H is fixed in a discharger V, just clear of the edge of the disk. A stop-clock is placed on a stand D, and records the rate of revolution of one of the shafts. When the gun is fired the shot begins to move, and as it travels along the bore, one of the wires of the plugs in succession, breaking the primary currents, and causing sparks to pass in the secondary current from the discharger V, to the disk A. A, which are in rapid revolution. The sparks burn off the lampblack and record their positions on the disks by a minute spot. Now if the shot could cut all the plug-wires simultaneously, all the spots on the disks would be in a straight line, but it does not do so, and during the intervals between the cutting of successive plug-wires the disk continues to rotate, so that the line of spots forms a spiral round the circumference of the disks between the spots are read off on the graduated circle. As the circumference of the disks is made to travel at the rate of 1100 inches per second, and the vernier reads to thousandths of an inch, the machine indicates portions of time rather less than a millimetre of a second; it is, in fact, practically correct to hundred-thousandths of a second. A millimetre is about the same fraction of a second as a second is of a fortnight. The

distances between two successive spots gives the actual time occupied by the shot in moving over the portion of the bore between two corresponding successive plugs, and therefore the velocity required at some point of this travel. As the *increment* of velocity is constant decreasing after the change is fairly lighted, the point at which the measured velocity is acquired is very slightly behind the middle of the space between the two plugs. The observations are worked out, accidental error eliminated, and the results put in the form shown in column 3 of Table I.

The "crusher gauge" (fig. 8) is so closely associated in Cranah's use with the Noble chronoscope that it is convenient gauge to give a description of it here, though its indications are

Fig. 8.—Crusher gauge.

valuable to the gunnarmaster rather than to the gunner. In fig. 4 are shown three plugs, A, B, and C, driven through the walls of the gun, and terminating flush with the bore. These plugs contain gauges for measuring directly the pressure of the gas on the surface of the bore. They are of the same diameter as the cutting plugs, and can be used in any of the twenty-one holes pierced in the gun. Fig. 8 shows the construction. The bottom of the plug is chambered out, and a steel anvil E is placed at the top of the chamber. Against this anvil is pressed a cylinder of pure copper A, carefully tested for quality, which is held in its place by a spring B. A piston C fits accurately the lower part of the chamber, any ingress

Pressures and velocities inside bore.

to produce the increments of velocity. These calculated pressures are compared with and confirmed by those obtained directly from the indications of the crusher gauge. Table I. shows the nature of the information obtained from

the combination of the two instruments, when used with a 38-ton gun, firing an 800-lb projectile, with 130 lb of 1.5-inch cubical powder.

Le Boulengé chronograph.

The last velocity is calculated from that taken by a Le Boulengé instrument outside the gun. This chronograph, the invention of an officer of the Belgian artillery, is shown in figs. 9, 10, and its mode of application in fig. 11.

FIG. 9.—Le Boulengé Chronograph, side view.

FIG. 10.—Le Boulengé Chronograph, front view.

The shot, after leaving the gun, cuts the wire of the first screen, and subsequently the wire of the second screen. The wire of the first screen conveys a current through an electromagnet A (figs. 9, 10), which then supports a cylindrical rod C. This rod is sheathed with a zinc tube D, which is renewed from time to time as required; several short zinc tubes are slipped on, instead of one long one, if no great variation in the velocities is expected, so as to save material. Directly the first screen is cut, the rod C,

FIG. 11.—Mode of using Le Boulengé's Chronograph. which is called the *chronometer*, drops. The wire of the second screen conveys a current through another electromagnet B, which supports a much shorter rod F, called the *register*. The shot, in cutting the second screen, releases this short rod, which falls on a dial O, setting free a spring M. This spring carries a horizontal long rod. The nick made by the knife, if released while the long rod is still suspended, is the zero point. The currents from both screens pass through a *disjuncter* by which they can be cut simult-

aneously. When this is done the long and the short rods fall at the same moment. A certain time is consumed by the short rod in reaching the disk, setting free the spring, and cutting a nick on the zinc. During this time the long rod is falling into a recess in the stand, deep enough to receive its full length. The instrument is so adjusted that the nick thus made is 4/485 inches above the zero point, corresponding to 0.15 sec. This is the *disjuncter* reading, and requires to be frequently corrected during experiments, unless the weather is exceptionally favourable to the electrical conditions. Instead now of using the *disjuncter* to cut both currents simultaneously, suppose the shot to cut them in succession; then the long rod will be falling for a certain time, while the shot is travelling from one screen to the other, before the short rod is released. The longer the shot takes to travel this distance, the farther the long rod falls, and the higher up on it will be the nick made by the knife. A simple calculation connects the distance fallen through by the rod with the time occupied by the shot in travelling over the distance between the screens, and hence its velocity at the middle point is known. A graduated rule is generally supplied with each instrument, arranged for a certain distance between the screens; from this any velocity obtained can be read off at once.

The electric chronograph, invented by Captain Watkin, Watkin R.A. is shown in figs. 12, 13, 14.

FIG. 12.—Watkin Chronograph.

Two brass cylinders A, A revolve on pivots B, B, C, C. Between them, at the top, hangs a brass weight (fig. 13), suspended freely by means of a piece of steel B, which pivots on another piece A let into the base of the weight. Two arms E enter, on falling, two V springs on the bed of the instrument, which catch the weight, A freely-pointed brass wire, CD, enclosed through part of its length in an ebonite tube, passes through the upper end of the weight from side to side; the piece B of the weight is placed between the ends of A, C of the lower arms of the holder (fig. 14). The arm CD pivots on the pin F; AB is fixed. K, K is an electromagnet; on its keeper H is fixed a strong spring G, G. When this spring is placed between the ends B, D of the arms, it forces the opposite end C to

press against A and to section the weight by gripping the piece B (fig. 13) of the weight. In this position the keeper H is at a short distance from the poles of the electromagnet. Directly the current is allowed to circulate, the keeper is attracted down to the magnet, the spring G is pulled up, and a small spring L passes on the arm CD, the jaw AD flies open and the weight is released. The two cylinders A, A (fig. 12) form part of the circuit of a secondary induction coil. The screws are similar to those employed for the Bush fast chronograph, they are fastened successively by the shot, which successively interrupts the primary current, and thus causes an induced current to pass through the cylinders A, A. As these,

FIG. 13.—Weight

FIG. 14.—Holder

however, are not in electrical connection, the current has to pass through the base wire of the weight, which is in the act of falling. The cylinders are covered with smoked paper, and the passages of the spark in and out last minute spots showing the exact position of the weight is the momentary velocity of the shot may be used, and a duplicate record is obtained in one experiment of the space fallen through by the weight, while the shot is falling each interval between the sparks. As before, a simple calculation converts time and space, and an invariable scale enables the experimentist to read off the velocities without the distance between the sparks.

In all these instruments slight errors exist, arising from mechanical imperfection, or from irregularity in the electric currents, still, the accuracy arrived at is sufficient for practical purposes, as is well shown by the following table—

TABLE II.—Velocities of Metallic Heavy Bullets fired with two different Charges, observed with several Instruments

These instruments enable the experimenter to ascertain the velocity of a projectile up to considerable distances from the gun. With little ordnance no difficulty is found in hitting screens of moderate size at a range of 2000 yards, and, practically, the loss of velocity due to the resistance of the air can be determined for all ranges and all velocities.

It might be supposed that, having the means of acquiring this knowledge, the artillery would find little difficulty in solving the grand problem of his art, which may be thus briefly stated—Given a projectile of known weight and dimensions, starting with a known velocity at a known angle of elevation in a calm atmosphere of approximately

known density, to find its range and time of flight, its velocity, direction, and position at any moment,—or, in other words, to construct its trajectory. This state of perfection has, however, not yet been reached, mathematics has hitherto proved unable to furnish complete formula satisfying the conditions. The resistance of the air to slow movements of, say, 10 feet per second seems to vary with the first power of the velocity. Above this ratio increases, and, as in the case of the wind, is usually reckoned to vary with the square of the velocity, beyond this it increases still farther, till at 1200 feet per second the resistance is found to vary as the cube of the velocity. The ratio of increase after this point is supposed to diminish again, but thoroughly satisfactory data for its determination do not exist. From this it would appear that, as the velocity of the shot increases in rapidity, the air finds continually greater difficulty in filling up the space left by the advancing projectile, but that, when once a point is reached where the vacuum in rear is complete, further increase of speed only encounters additional difficulty in displacing the air in front. The difficulty of meeting the conditions by mathematical formula is very great, since the velocity of the projectile changes continually, and moreover is resisted by air continually varying in density as the shot rises and falls again. It is evident that the greater the weight of a shot in proportion to the column of air displaced by it, v , e , to the square of its diameter, the less effect will the resistance of the atmosphere have upon its motion, thus very heavy projectiles moving with very low velocities will be but little retarded by this cause. It is desirable, therefore, before proceeding to explain what has been done towards Trajectories the complete solution of the problem above stated, to establish the limit, and investigate the trajectory when the resistance of the air is neglected.

FIG. 15

Let v = muzzle velocity of projectile,
 e = angle of elevation,
 t = time of flight

Let the projectile start with velocity v from the point O (fig. 15) in the direction OM, so that MOX is the angle of elevation. Let OM be the distance which would be traversed in a period of time t , if gravity did not act. Draw ON vertically downwards, equal to the distance through which the shot would fall in time t under the action of gravity only. Complete the parallelogram OMPN. Then P will be the position of this projectile at the end of the time t . We have then—

$$OM = vt, \text{ and } ON = MP = \frac{1}{2}gt^2$$

$$\text{Therefore } OP = \frac{2v^2 \sin e \cos e}{g}$$

Since OM bears a constant ratio to MP, the trajectory is a parabola, having its axis vertical, and OM for a tangent.

Again, the horizontal velocity = $v \cos e$, and remains uniform; the vertical velocity = $v \sin e$, and is acted against by gravity. Then—

$$u = OQ = vt \cos e$$

$$y = PQ = vt \sin e - \frac{1}{2}gt^2$$

Com
 putative
 velo
 cities

Eliminating u , we get—

$$y = x \tan \epsilon - \frac{g x^2}{2c \cos^2 \epsilon}$$

which is the equation to the trajectory, and is a parabola. To find the angle, put $y=0$, the two resulting values of x give the position of the gun, and the end of the range, thus, $0R = \frac{u^2 \sin 2\epsilon}{g}$.

In Robius' experiments in 1743 and subsequent years, it became apparent that up to a certain point the resistance of the air increased with an increasing power of the velocity. Mutton in 1790 placed this point at 1600 f s., and concluded that the ratio decreased after this velocity was passed.

He proposed as a formula for the resistance $R = c v + b v^2$. General DuRoi, in 1840, deduced from the experiments at Metz the formula $R = c v + b v^2$. The experiments withuffed projectiles carried on at Clavis in 1861 led Professor Hilde to the conclusion that the resistance of the air at practical velocities was more nearly proportional to the cube of the velocity than to any other working expression. He constructed a formula for the trajectory by empirically modifying the formula given above for the path of a projectile *in vacuo* thus—

$$y = x \tan \epsilon - \frac{g x^2}{2 \cos^2 \epsilon} \left(\frac{v}{v_0} \right)^n$$

from which he deduces an expression for the range which at low elevations for velocities between 800 f s. and 1400 f s. is very fairly accurate, and which furnishes the simplest method yet devised of roughly constructing a range table—

$$r = \frac{1}{2\lambda} \left(\sqrt{1 + 2\lambda} \frac{2v_0^2 \sin 2\epsilon}{g} - 1 \right),$$

where

r = range in feet,

v = velocity in feet per second,

λ = angle of elevation,

$\lambda = 0.000000128 \frac{v^2}{g}$,

d = diameter of projectile in inches,

w = weight of projectile in pounds,

g = accel. of gravity = 32.19

The above value of λ is given for ogival heads, with hemispherical, pointed, in fact heads a different coefficient of resistance would be required. The ogival is the form which suffers least retardation from the air. The most complete and valuable series of experiments yet carried out is that of Professor Bashforth (1865 to 1370) at Woolwich and Shoeburyness. He found that velocities and forms being equal and similar, the resistance varies exactly as the square of the diameter of the projectile. He further arrived at the conclusion that between 900 and 1100 f s. $R \propto v^2$, between 1100 and 1350 f s. $R \propto v^2$, and above 1350 f s. $R \propto v^3$. These results confirm in great measure those previously obtained, but unfortunately do not lend themselves readily to the construction of mathematical formulae.

Bashforth adopted the cubic law as his basis, as it offers the least difficulty in manipulation, and, putting $R = c v^3$, made the coefficient c a variable, the values of which he has tabulated. His method consists in building up the arc of the trajectory bit by bit, taking each portion so that a mean value of c for that portion may be used without important error. The path of the projectile may thus be constructed with almost any desired amount of accuracy, but the process is excessively laborious, and requires the use of a lengthy set of tables which cannot be reproduced here. For a complete knowledge of the subject the reader is referred to Mr. Bashforth's work. Mr. Bashforth, however, tabulated the loss of velocity due to the resistance of the air with regard to the time and distance of the shot's flight, and subsequent experiments carried out by the War Office in 1878-79 have now confirmed and extended the results he had previously obtained. As most of the problems of modern gunnery can be approximately solved by the use of these tables, we give in Table III an abstract with explanation.

TABLE III.—Loss of Velocity of a Projectile in Time and Distance

The rate of loss of velocity is here inversely treated for an ogival projectile having a weight in pounds equal to the square of its diameter in inches. Thus a 18 lb. projectile of 3 in. diameter, starting with a velocity of 2600 f s. would retain a velocity of 400 f s. at a distance of (26,000 - 5000) = 21,000 ft. after a time of (24.168 - 5.000) = 19.168 seconds. As the value of c^2 decreases the resistance of the air retards the projectile less, thus if the 3-in. shell weigh 18 lb. it will overcome the resistance twice as well as the 9 pounds, since its $c^2 = 0.5$ instead of 1.0.

Example 1.—The 60 ten gun fires at a vessel in motion at a range of 2000 yds. The muzzle velocity is 1330 f s, the caliber 16 inches, and the weight of projectile 1700 lb. Required the velocity on impact, and the time of flight.

$$\begin{aligned} \text{I.L.C. } \frac{d^2}{dt^2} &= 16' = 0.1606 \\ &= \frac{1700}{1700} \\ 0.1606 \cdot 6000 \text{ ft.} &= 903 \text{ ft.} \end{aligned}$$

Selecting the $m = 1580 \text{ f s}$ in the first column, the second column shows 23,619 ft. Subtracting, $1330 \text{ f s} - 903 = 23,616$. Running up the second column and using proportional parts, this number corresponds to a velocity of 1383 f s, which is the velocity on impact, showing the projectile to have lost 197 f s of its velocity during flight. In the third column, opposite 23,616 feet, we find 31.920 seconds. Subtracting this from the time opposite 1680 feet, and dividing by $\frac{d^2}{dt^2}$, we have

$$\begin{aligned} t &= \frac{1}{1580} (32.544 - 31.929) \\ &= 0.1084 \text{ seconds} \end{aligned}$$

Example 2.—An observer in an earthwork notes the flash of a hostile gun, in 31 seconds the shell (broad) leaves itself in the target, followed in half a second by the report of the gun. The shell is dug out, and found to weigh 60 lb, and to measure 15 cent meters in diameter. Required the range, the muzzle velocity, and the striking velocity.

The range is here given by the velocity of sound, which travels through air at an average rate of 1140 feet per second, so that

$$\begin{aligned} r &= 3.76 \times 1140 = 4276 \text{ ft.} \\ \frac{d^2}{dt^2} &= \left(\frac{16 \text{ cm}}{60} \right)^2 = \left(\frac{15.23 \text{ ms}}{60} \right)^2 = 0.6391, \end{aligned}$$

$$\frac{d^2}{dt^2} = 2498 \text{ ft.}, \text{ and } \frac{d^2}{dt^2} = 1892 \text{ sec}$$

We have now to consider what muzzle velocity will cause the projectile to traverse the given distance in the given time. It must move at a mean speed of 1315 f s. Assuming the muzzle velocity to be 1600 f s, corresponding to this we find 23,607 feet and 32.609 seconds. Subtracting from these the reduced range and time, we have 31,119 feet and 30.707 seconds, if the velocity has been correctly assumed, it is clear that the range and the time of flight should result in the same terminal velocity. In the present instance, opposite 23,119 feet stands 1140 f s, while opposite 30.707 seconds stands 1135 f s. Thus it appears that the velocity has diminished more or less in the time it travelled than in the distance travelled. This shows that it is assumed too high. Trying 1684 f s, and proceeding as before, each column indicates 1120 f s, which therefore is the terminal velocity, showing that the projectile has lost 464 f s of its speed during flight.

Drift.—Projectiles fired from rifled guns do not move in a vertical plane, but deviate to the right or to the left according to the direction of their rotation. All nations have adopted the right-handed twist, probably because it happened to be selected first. If the observer stands in rear of the piece and looks at the gun when fired, the projectile rotates in the same direction as the hands of a watch. It then steadily veers away to the right. The reason of this is not very clearly understood, in fact, two rival theories are put forward to account for it. If there were no resistance of the air, the path of the shot would be a parabola, and the axis of an elongated projectile would remain parallel to its original direction. The resistance offered by the air causes the axis to tend to assume a position tangential to the trajectory. On leaving the gun the projectile moves in the direction of its axis, which is also the direction of the axis of the gun. The action of gravity soon causes the path of the shot to make a small angle with the original direction of the axis, that is, the trajectory soon deviates from a straight line, the axis of the projectile is urged by the resistance of the air to accommodate itself to the new path, but as the path is constantly changing, the axis is always too late, since the rotation tends to preserve its parallelism. Thus there is always an angle—depending in amount on the velocities of rotation and translation, weight of shot, and density of the air—between the axis of the shot (AB) and the trajectory CD (fig. 16). Thus far both theories agree as to the facts, but they differ as to the deductions. The first view is that the resultant resistance of the air,

which has the effect of a force in the direction DC, tends to turn the shot about an axis passing through G, and perpendicular to the plane containing BGD, so that if the shot had no rotation, it would turn end over end. But as it has a right-handed twist, this motion is combined with that which the resistance of the air tends to impart to the shot, and the point A is therefore slightly deflected to the right at first. Continuing the action, the axis GA describes a cone about CD, rotating in the same direction as the shot rotates about its own axis. The resultant of the air's resistance tends to increase the angle BGI, therefore the shot will have a sinuous motion, but as the first deflection

Fig. 16

is to the right, and afterwards the point is more to the right than to the left, the deviation will on the whole be to the right. The other view is that, as the axis of the shot is always directed a little above the trajectory, the resistance of the air meets the surface on the under side, on which therefore there is more pressure than on the upper side. The consequence of this is that the friction of the air with the rotating surface is greater below than above, and this force causes the projectile to roll bodily to the right while travelling forward. The path thus curves away from the vertical plane, and the resistance of the air tends to cause the axis to lose its parallelism with that vertical plane, though it is, as before, too slow in altering its direction to

FIG. 17.—Correction for deflection.

become tangential to the curve described. Crucial experiments to test this point at rest are as yet wanting. The "drift" or "deflection" is usually corrected in the Dutch service by inclining the tangent sight. The result of this is that as the range increases, the higher the sight is raised, and the farther is the eye-notch to the left of the vertical plane containing the axis of the gun. In the German service the tangent sight is placed vertically in the gun, and the deflection is allowed for by a graduated sliding leaf in the head. The same arrangement is used in those British guns, as the howitzers, which fire variable charges, as the slope of the tangent sight will accurately suit only one muzzle velocity.

To explain the correct slope, the actual deflection is determined for each gun on the practice ground at various ranges with a vertical sight; then, in fig. 17, AD is the line of sight when the axis of the gun is horizontal. CD is the line of sight with a vertical tangent sight set at the angle of elevation ADC required for the range DF. Since the projectile deflects to the right, it is necessary that the line CD should point to B in order to hit F. This is accomplished by inclining the tangent sight AB, so that BC shall give the requisite allowance. The relation is thus established. By similar triangles,

BC = EF, then BC = AC tan LAC, and CD = AC cos AC, so
 CD = FD. Putting the angle ADO (the de-
 clination) = α , the angle BAC (the slope of the tangent sight) = θ ,
 LE (the deflection) = δ , and DE (the range) = r , we have tan δ =
 $\frac{r}{d} \cos \theta$.

The action of the powder charge, the travel of the projectile along the bore, the rifling, and, speaking generally, what takes place inside a gun when fired, are matters specially connected with the designing and manufacture of ordnance, and are therefore treated under GUNMAKING.

Projectiles.—The requirements of modern artillery have necessitated many complications in the preparation and use of projectiles, which now vary greatly in their nature and in the purposes for which they are employed. A general description of the several kinds supplied to European armies will be found under **ARMYARTILLERY**, and but few remarks will be required to connect them with the guns for which they are intended. Smooth-bore ordnance use solid round shot and case, common shell, and diaphragm shrapnel shell. Solid shot are used against masonry, wooden shipping, and masses of men. They were at one time fired red hot at shipping. Roughly, the cube of the diameter in inches multiplied by 0.135 gives the weight of the shot in pounds. Case shot consist of iron balls packed in iron or tin cylindrical cases. They are effective up to about 350 yards against troops, boats, and rigging, and are especially suitable for flanking detachments. Common shell are completely filled with powder, and are burst in flight by time fuses, or, on striking, by percussion fuses. They are used against men in masses, buildings, works, and material generally. Diaphragm shrapnel shell contain a small bursting charge and a number of balls. They are fitted with a time fuse which explodes the charge when they near the object, so that the released bullets fly forward. They are very destructive against troops. In addition to the above projectiles, incendiary shells, called *carcasses*, filled with a violently burning composition, are thrown into villages and amongst shipping. Ground light balls cast among the enemy's working parties at night disclose their position. Parachute light balls contain a parachute tightly folded up, and a cup of illuminating composition; they are fired with a fuse timed to burst in the air, and they then remain suspended for a time, throwing a light down on the enemy's working parties.

The great advantage of rifling was long recognized in small arms and sporting pieces before it was extended to ordnance. The first rifled arms threw bullets which, except for certain projections designed to fit the groove of the barrel, were spherical. These guns surpassed smooth-bores in accuracy, but it was not till the introduction of elongated projectiles that a distinct gain in power was recognized. The gain in accuracy is due in great measure to the superior correctness with which the ball is centred in the bore by the action of the groove, while the rotation imparted to it annuls or greatly lessens the disturbing effect of the pressure of the air on surfaces inequalities, or of variations in the position of the centre of gravity. An elongated shot is also enabled to travel point first, or nearly so, and as the resistance of the air depends upon the area of the transverse section, a far greater weight can be given to the long than to the round shot without increasing the resistance. Thus, in addition to greater accuracy, rifling confers a flatter trajectory and greater penetration. The elongated form presents a head of the best shape, an increase in the contents of the shell, and the use of fuses which explode when the point strikes an object. The projectiles used with rifled guns are case shot, common shell, shrapnel shell, and Palliser shell. The case shot differ little from those made for smooth-bore ordnance. Common shell are generally

from 2½ to 3 calibres in length. They are designed to contain as much powder as possible, consistently with shell strength of wall to resist the shock of firing. Their effect is almost entirely due to explosion, velocity has little to do with it beyond conferring range and penetration. Common shells are generally fused with percussion fuses. They are effective for breaching, for setting fire to buildings, against troops if not much scattered, and especially against wooden or thinly plated vessels. The introduction of iron-clad ships is almost entirely due to the terribly destructive fire of shells. Shrapnel shell are filled with bullets, and shrapnel have a bursting charge only sufficient to open the case and release the contents, which then fly forward with the velocity possessed by the projectile before breaking up. The bullets and fragments very speedily lose this velocity after separation. It is therefore most important to judge the range correctly and to form an accurate estimate of the practice, so that the result of each round may guide the aiming and timing of the next. When the shrapnel is burst in the air by a time fuse, it is exceedingly difficult to judge its precision by the puff of smoke. The splashes or puffs of dust of the bullets striking the ground should therefore be carefully looked for. When the shrapnel is burst on striking the ground by a percussion fuse, it is much easier to estimate the accuracy of the shooting, and it is common therefore to get a range by firing a round or two with percussion fuses before using time fuses. If the ground is hard and the distance of the enemy such that the shell strikes at but a small angle of descent, percussion fuses generally burst the shrapnel better than time fuses, which, in these cases, have the advantage at long ranges and over soft ground. For field service time-fused shrapnel should be burst at from 50 to 100 yards in front of the object, and about 10 to 15 feet above the ground. The cone of dispersion of the bullets and fragments is considered to be so proportioned that the diameter at any point of the axis is one-third of the distance of that point from the burst or apex. To get satisfactory results from time fuses it is necessary to have a gun which shoots with great regularity, a fuse composition which burns evenly, and an accurate mode of setting the fuse. Of late years improvements in powder and design of ordnance have rendered the velocities practically uniform. The fuse composition is somewhat liable to deterioration, but is tolerably satisfactory, and a new fuse composition has just been introduced which can be set to any desired degree of accuracy. As the power of shrapnel shell is entirely due to the velocity possessed by the bullets when fired from the envelope, it is of paramount importance in long-range firing that the shell should start with a high velocity and retain as much of it as possible. It is considered that with field guns the velocity of the projectile at the moment of bursting should not fall below 800 ft. s., otherwise the contents will have a much diminished effect. The bullets themselves should retain a velocity of about 500 ft. s. on striking to be thoroughly effective. With the more modern field guns the effective range of shrapnel extends up to about 3000 yards, with heavy guns to 4000 or even 8000 yards.

Palliser shells are made of a mixture of selected brands of iron, and are cast in moulds so constructed that the periphery of the head is in contact with iron and that of the body with sand. The head is thus "chilled," as the rapid carrying off of the heat by the iron mould causes the particles of the metal to dispose themselves rigidly, and confers intense hardness, which property is essential for the penetration of iron plates. The head is of the ogival shape, that being found most effective in combining strength with sharpness (fig. 18). It is a moot point whether projectiles of hardened steel are more effective than those of chilled iron against armour. Probably the steel can get through a

Smooth
bore
pro
jection

Rifled
pro
jectiles

greater thickness, but the damage done by the fragments of the Palliser after perforation is more serious. The cost of the steel shell is about five times that of the iron ones. The bodies are cast in sand, because extreme hardness is not there required, and a sounder casting is thus obtained. No fuses are used with these shells; they are burst by the shock of impact on armour which explodes the powder charge. It is doubtful if they would explode on striking iron vessels not armour-plated, and they would fail to burst on striking wooden ships. They are effective in destroying masonry, and have been driven through great thicknesses of stone. They hold about a quarter as much powder as common shell of the same diameter. The greatest penetration of armour yet known was obtained by the 80-ton gun at Shoeburyness in 1877. The target consisted of four 8-inch wrought-iron plates, sandwiched with three 8-inch layers of teak, the whole put together with immense strength. The projectile perforated three plates and the teak, digging its nose about half-way into the last plate, which was much cracked and bulged. The 100-ton gun has perforated with ease 32 inches of solid wrought iron plate strongly backed, but failed to drive a hole through a similar target when the plate was of steel. Very recently extraordinary penetration has been obtained by a 6-inch 70-pounder made by Sir W. G. Armstrong & Co. Fired with a velocity of nearly 2000 f. s., this small projectile pierced about 11 inches of wrought iron. The subject of penetration is treated under GUNMAKING.

FIG. 18.
Palliser shell.

A description of some of the fuses and firing tubes used in gunnery will be found under AMMUNITION. The general principle guiding the selection of time or percussion fuses is that when a shell is required to burst in the air a time fuse is employed, when on striking an object a percussion fuse is chosen. In muzzle-loading guns (not using gas-checks), time fuses are ignited by the flash of discharge; otherwise the shock is taken advantage of to light the composition by exploding a detonator. Percussion fuses are sometimes found to act too rapidly; where it is desired that penetration to a certain depth in earth or other material shall take place before explosion, it is found necessary to slow the fuse by interposing a small column of composition, burning for a quarter of a second, between the detonator and the bursting charge. In firing a heavy shell with high velocity at a weak vessel, the resistance of the side is so slight that it may happen that the fuse either fails to act (the shell not being sufficiently retarded to set it in action), or explodes the shell after it has passed through both sides. To meet this case a specially sensitive and rapidly-acting fuse has been devised.

Guns were formerly primed with loose powder and fired by a match, next by common quill tubes filled with composition and ignited by a porifire, then by detonating tubes exploded by a hammer. Now friction tubes have superseded these methods for ordinary service. When it is desired to fire a gun from a distance, or to fire a number of guns absolutely at the same moment, Abel's electric tubes are employed. In them two fine copper wires pass down through the head, insulated by gutta serena, except at the ends, which are separated by $\frac{1}{16}$ th of an inch of a composition of subphosphide and disulphide of copper with chloride of potash. The other ends of the wires are in contact with the copper lining of two holes in the head. The wires from the battery are placed in these holes; when the current passes, the composition is heated to ignition and explodes the tube.

Service of Ordnance.—The general principles guiding the

employment and manipulation of artillery are applicable to the schemes of warfare of all civilized nations. Slight differences exist in calibre and weights; but it may be taken that the considerations which regulate the service of English guns have the same force elsewhere. The details of manufacture, the systems of loading, and the methods of rifling, are the chief points regarding which artificers differ; these matters are treated under GUNMAKING. Of two pieces constructed with equal skill to perform the same kind of work, the heavier will always be the more powerful. Thus weight is the chief controlling element in the employment of guns, though cost and convenience of manipulation have often to be taken into account. The artillery of the present day is the outcome of a long series of improvements, and the whole system of this important arm bears traces of frequent modification and continual compromise. The first introduction of firearms appears to have taken place in England in the reign of Edward III. On the Continent it was probably somewhat earlier, but the actual date and the circumstances attending their introduction are involved in obscurity. It is said that cannon were used in the English expedition against Scotland in 1327, and at the battle of Crecy in 1346. In 1560 there were four copper guns in the Tower. For about two centuries cannon continued to be manufactured of copper, brass, or bronze; good castings of which were made long before the art of smelting iron ores was perfected. In the early part of the 16th century guns were sometimes made of wrought iron plates put together longitudinally and hooped with wrought iron. In 1545 cast iron ordnance were manufactured in England, and supplanted pieces of all other materials for a time. The growing needs of warfare, however, soon demanded guns possessed of fair mobility to accompany armies in the field, and the cast iron pieces used being found against the cumbersome, bronze was once again resorted to for field artillery. From about the middle of the 17th century till the introduction of rifled cannon, all the heavier nature of ordnance—fortress, siege, and ship guns—were made of cast iron; and all the lighter—field and boat guns—of bronze. In 1717 the bronze foundry was established at Woolwich, and most of the smooth-bored field pieces, howitzers, and mortars used in the service were made there. The heavy cast iron guns were supplied by contractors, and proved by Government officials. The long peace which succeeded the Napoleonic wars was highly unfavorable to the progress of gunnery, but great developments took place in the arts and sciences, so that, on the breaking out of the Crimean War, the latest discoveries in metallurgy and the excellence attained in machinery at once enabled inventors to make a great advance in artillery. At the transition period, a few wrought iron smooth-bored, throwing spherical shot of 150 and 100 lb, were manufactured to overcome the resistance of iron plates then recently introduced for armoring ships. These pieces were speedily discarded for rifled guns; and practically it may be said that the adoption of steel and wrought iron for guns coincided with the change from smooth-bored to rifles, both steps of progress being thoroughly established about 1860. In spite of the great superiority of the new ordnance, it cannot be said that the old pieces are yet superseded; vast numbers of them exist over all parts of the world, and often form the only defence. Even the fortifications in England are still largely armed Smooth-bored ordnance. with them on land fronts; and though they are gradually disappearing, they yet claim notice. Bronze guns are now obsolete in the British service. Figs. 19 to 24 show typical kinds of cast iron ordnance. These denominated according to the weight of their projectile and made strong enough to fire solid shot or shell; those called by the diameter of the bore fire shell only. It must be remembered that, with spherical projectiles, the solid must be heavier than the

Electric tubes.

hollow kinds, which need not be the case with rifled ordnance, as the projectile may be of any length. The guns are used for direct fire, the howitzers for curved fire, the mortar for vertical fire, i.e., they are set at 45° elevation, and the requisite range attained by varying the charge of powder, instead of firing at various degrees of elevation, as with guns and howitzers.

The old field smooth bores were fairly effective up to 1000 or 1200 yards, and so established a great superiority over the smooth bored musket, but as soon as the rifled musket was generally adopted, an advance in artillery power became necessary if the arm was to retain its position in the scale of efficiency. After the Crimean War Napoleon III rifled his bronze field guns on Treuille de Boanlen's system, and the new pieces exhibited great merit at Magenta and Solferino in 1859. England, and indeed every

the Continental powers for the most part endeavoured to improve their methods of breech-loading. In 1872 the British wrought iron and steel muzzle-loading 9-pounder of 8 cwt had been introduced into the service,

FIG. 19—18 pounder Gun. A, button (ascrible), B, breeching loop (do), C, breech, D, hoop ring and hoop; E, vent field, F, vent field astragal and fillets, G, 1st reinforcement, H, 1st reinforcement ring, I, 2d reinforcement, J, 2d reinforcement ring and hoop, K, pritch for sighting, L, chase, M, muzzle astragal and fillets, N, neck, O, point of muzzle, P, muzzle mouldings.

and the 16-pounder of 12 cwt, of similar construction, was being brought forward. Against these guns the Prussian 6 cwt field breech-loader had no chance. Its lightness was almost its only merit. Throwing common shell with percussion fuzes (which were useless on soft ground), having but a poor muzzle velocity, and suffering much from retardation by the air, its effect was feeble compared with that of the British 9-pounders, which threw with 800 f s more velocity a time-fused shrapnel of excellent construction, while the 16 pounder, although not equally fortunate with the 9-pounder in the attainment of its projectile, yet by sheer power and weight of metal engaged in deadly effect every field gun in existence. England's field artillery was undoubtedly the most powerful known at that period. No one was more alive to this fact, or more dissatisfied with

FIG. 20—8 inch Howitzer

European power, was busily engaged in experimenting during this period. The early Armstrong guns in England, Broadwell's and Krupp's in Prussia, and imitations of the French plan in other countries, speedily caused field artillery to regain its place in war. The northern kingdoms of Denmark and Norway and Sweden, favoured by specially

FIG. 21—32 pounder Cannonade

good iron ores, and free from the immediate alarm of war, retained cast iron as the material for light ordnance. Prussia had already begun to use steel for smooth-bores, and naturally adhered to it for rifled guns, while the coil system brought forward by Armstrong was found cheap and enduring in England. The new Prussian guns were breech-loaders, constructed on the double-wedge system, they proved unsatisfactory, and since the Franco-Prussian war of 1870-71 have been abandoned in favour of a single-wedge system of great neatness and efficiency. The Armstrong guns were also breech-loaders, and when tested by land and sea, on actual service in China, New Zealand, and Japan, proved to be very powerful when compared with the old smooth-bores, but also exhibited many defects of construction. At this time no thoroughly successful breech-loader had been invented, and England reverted to muzzle-loading, while

ordnance

FIG. 23—10 inch Shell Gun

it, than the Germans. Their great gunmaker, Krupp, forthwith improved his breech-closing fittings, and instituted series upon series of experiments till he produced two guns—one for horse artillery, and one for field batteries, also horse—both of which were an enormous advance on the weapons field previously employed against the French. The lighter gun gun weighs 7 cwt, and throws a shell of 11 lb weight, with a muzzle velocity of 1525 f s, the heavier weighs 9 cwt, and throws a shell of 17 lb weight, with a muzzle velocity of 1460 f s. These are figures indicating power not to be attained by the English 8 cwt gun, or even the newer pattern of 6 cwt throwing a 9 lb shell with a muzzle velocity of 1390 f s, and the 12-cwt gun, throwing a 16 lb shell with a muzzle velocity of 1360 f s. The immediate consequence of the introduction of these improved German pieces was

FIG. 24—Cobden Howitzer

the instituting of a series of experiments in England which resulted in the production of a muzzle-loading field gun, weighting 8 cwt, and throwing a 13-lb projectile with a muzzle velocity of 1560 f s. Shrapnel shell from this gun will retain velocity over 800 f s (the speed below which they cease to possess high efficiency) up to 8500 yards range. In this new gun advantage is taken of all the latest improvements, such as an enlarged powder chamber, increased length of bore, polygroove rifling, rotation by gas-check, and powder specially adapted to the piece. Although the introduction of this field gun once more places English light-artillery in the van, further progress is near. Sir W

G. Armstrong & Co. are now (1879) experimenting with field guns, both muzzle and breech-loading, yielding velocities of 2000 f. s., and no doubt a fresh development of the new principles of air-spacing and -chambering (already initiated in the Royal Gun Factories) is at hand (see GUNMAKING).

FIG. 25.—40-pounder Armstrong Rified Breech-loader.

never earned adoption. Subsequently the breech-loaders have been gradually ousted by 25-pounder, 40-pounder, and 64-pounder muzzle-loaders, with 8-inch, 6.6-inch, and 6.3-inch howitzers, new patterns of which latter pieces have just passed their early trials. The 64-pounders were introduced in 1864. For naval purposes the calibre was chosen so that

FIG. 26.—40-pounder Breech Screw.

32-pounder round shot could be fired from it on emergency. The 40-pounders are stronger, and fire much heavier charges than their breech-loading congeners. The 25-pounder was introduced in 1874 to supersede the 20-pounder breech-loader for light siege trains, and as a gun of position. Ever since 1853 experiments have been carried out by the Eng-

FIG. 27.—40-pounder Vent Piece.

FIG. 28.—40-pounder Vent Piece (section).

lish and other nations for the improvement of mortars and howitzers, first in a smooth-bored and then in a rifled state. These experiments are still in progress, and it cannot be said that the art of throwing heavy shell at high angles has as yet arrived at perfection. In 1872 short pieces throwing shells of 180 lb and 64 lb were adopted,

The history of the progress of siege guns would be in a large measure a repetition of that of the field artillery guns. Briefly, the smooth-bored siege train of cast-iron 18-pounders and 8-inch howitzers was replaced in 1859-63 by ones composed of 20-pounders, 40-pounders (figs 25-28), and 7-inch rifled breech-loading pieces, with certain howitzers which

but recently longer and more powerful shell-guns have been tried, throwing heavier projectiles with greater accuracy. In these new pieces polygroove rifling with gas-check rotation affords a hope that the necessary precision may be attained.

The "converted guns" must not be passed over, since they are largely employed to arm our land fronts and to retard the advance of the enemy's forces. When first elongated rifled projectiles were introduced, a great many methods of strengthening the old cast iron ordnance were proposed. The most satisfactory was that put forward by Palliser, and consisted of lining bored-out cast iron shells with wrought iron tubes. Some of the smaller men-of-war carry these pieces, but the great majority are used only for the secondary purposes above mentioned. The 32-pounders of 58 cwt., and the 8-inch shell-guns of 65 cwt., have thus become 64-pounders, and the 68-pounder of 95 cwt. has become an 80-pounder.

Important as are the land-service pieces of the army to England, yet, viewing her naval supremacy as one of the chief sources of her greatness, we must consider heavy ship and coast-defence ordnance to take the first place in modern gunnery. The contest between guns and armour has now continued with scarcely any intermission for upwards of twenty years, during which time the armour has increased in thickness from 4 to 24 inches, and the guns from 68-pounders to 2000-pounders; that is, from the most powerful of the old cast-iron smooth-bored to the 100-ton gun. The first armour-piercing rifled guns were the 7-inch Armstrong breech-loaders, but their supremacy was of short piercing duration. They were the heaviest made on that system, and were speedily succeeded by far more powerful muzzle-loaders. In 1867 8-inch and 9-inch guns had already been introduced. The 9-inch Woolwich rifled gun of 12 tons was tried in competition with the 11-inch American smooth-bore, which weighed nearly half as much again, against armour. The British piece gained a decisive victory. In 1868 it was decided to introduce a 10-inch gun of the same character. Since that time progress has been continual, and the latest productions of the three great gun-producing establishments of the world are the 71-ton steel breech-loader, recently tested, of the German maker (Krupp), the 80-ton muzzle-loader of Woolwich, and the 100-ton muzzle-loader of the Elswick firm (Sir W. G. Armstrong & Co.).

Tables IV. and V. show all the principal rifled guns in the land and sea services of Great Britain. It has always been an object with the authorities to assimilate the guns of the two services as far as their respective requirements will permit, and so to avoid multiplication of stores at the numerous home and foreign stations where supplies are made; but still it will be observed that considerable differ-

ances exist, and, judging from the progress of events, it appears likely that these differences will increase, because, as the science of gunnery becomes developed, each new kind of gun is more exactly fitted to the performance of the special work for which it is intended, and therefore less suitable for other purposes.

Table IV shows five distinct classes of rifled ordnance. 1. The heavy *armour-piercing* guns (figs 29, 30) are mounted round our coasts in casemates and barbette batteries. Their

function is to protect the British shores from the attack of nomadic ships, wooden vessels, and boats. They are accordingly provided with Palliser projectiles, common shells, and

a small proportion of shrapnel shell. In order to strike vessels steaming past at high speed, great accuracy, combined with rapidity of fire, is requisite. The guns are

aimed either by eye or map, according to the nature of the coast. In the former case, the detachment commander estimates the range, gives the necessary elevation by means

FIG. 29.—100-ton Gun (section).

of the tangent sight, directs the line of fire according to his judgment, jumps down and gives the word to fire—allowing for the vessel's motion and the time of the projectile's flight.

The map system has been recently perfected by Captain Watkiss's R.A.

Watkiss's
map
system.

In the whole navigable front commanded by the battery is plotted down in small squares numbered and lettered. Tables of the distances of the centres of these squares, the degree of training on the traversing are required to lay the gun on the desired square, together with the actual elevation necessary to deposit the shot in that square, are constructed for each group of guns.

FIG. 30.—100-ton Gun (section of groove).

FIG. 31.—Watkiss Position-finder.

In fig. 31 F is a fort defending the channel; ABFO the line of shore; O the object to be hit, a vessel passing. A, B, and C are stations of observation. In a convenient spot the commanding officer of the artillery in the fort places the map, over which play two arms A'O', C'O' kept constantly parallel to the two lines of sight AO, CO, by means of mechanism actuated by currents of electricity transmitted by a cable connecting A and A', C and C'. As A'O' represents, on the scale of the map, the distance AC, the junction O' represents on the same scale the position and distance of the object O. Tell-tales are distributed in the casemates, which constantly exhibit the number of the square over which the vessel is passing, showing the position of the ship, so that when the gun, or group of guns, are loaded, they can be either laid in the ordinary way, taking the range from the table, or, if the object is invisible from the casemate, by trailing the gun round till the number of degrees indicated by the tell-tale agrees with the reading on the traversing arc, and giving elevation to suit the range. The arcs showing the direction of the guns are so arranged that guns

trailed to any given number of degrees are parallel with each other. Supposing that from smoke or other cause the object cannot be distinguished from C, an observer is placed at B, and the arm is shifted from C' to B'. The practical working of the system is as follows. The commanding officer watches the course of a vessel as indicated to him by the arms on the map, the observers at A and C constantly following the centre of the object with their glasses. He telegraphs to the battery orders to load and lay, in accordance with the instructions given for each square of the map, and transmitted to the tell-tale. As the vessel passes over the square for which the guns are laid, the commanding officer can fire electrically the group of guns by pressing a key with his finger, or he may direct each detachment to keep up independent practice, laying in accordance with the indications sent by him through the tell-tale. The arrangements for exploding submarine mines or fixed torpedoes, where hostile vessels are passing close to them, are somewhat of the same character as those above described.

2. The *land-front guns* of fortresses shown in the table Guns of are intended to overpower and quell the fire of any places defence. which can be brought against them by a besieger. They are very largely supplemented in most fortified places by a number of the old smooth-bored guns and caronades, which are well adapted for the use of case shot at close quarters, for sweeping the glades, and for the defence of ditches. The rifled guns throw common shell into the siege works, and where possible among the enemy's material. They harness his working parties and reliefs with shrapnel, and endeavour to cut down his parapets and dismount his artillery by direct fire.

3. *Siege-train guns* accompany an army on a campaign Guns of where great mobility is not required, and where it is necessary to reduce fortified places. They should be the most powerful pieces which the means of transport will permit. In the more civilized parts of the world, where roads and climate are favourable, it is generally considered that about 70 cwt. is the heaviest weight of piece that can be carried with an army. In less favourable countries it is frequently impossible to transport more than half that weight. The early rifled siege-train guns were grouped into two classes.

A unit of the heavy train comprised—

64 yrs. of 84 cwt.	8
40 " of 35 " "	8
8" howitzers of 45 cwt.	14 (figs. 32, 33).

A unit of the light train comprised—

40 yrs. of 85 cwt.	10
35 " of 18 " "	10
6" howitzers of 15 cwt.	10

Lately 8-6" howitzers of 70 cwt. and 8-6" howitzers of 85 cwt. have been introduced, but their allotment has not yet been settled. Siege guns are supplied with special shell,

somewhat similar to Palliser projectiles, for penetrating masonry, also with common and shrapnel shell. The howitzers rarely use shrapnel shell. On first attacking a fortress at a long range, the duty of the guns is to cut down the defender's projectiles, dismount his artillery, dismantle his ramparts, and subdue his fire, so as to facilitate the con-

FIG 32—8 inch Howitzer, 46 cwt (section)

situation of batteries, near or the place. In the moon while the howitzers lob heavy shell into his works, and bombard the town, it necessary. As soon as practicable, branching batteries are thrown up in such spots as may be found suitable for the attack of a weak point. It is rarely possible to breach by direct fire in the case of works of modern

FIG 33—8 inch Howitzer (section of groove)

design. Here it is that curved fire is so effective, and here it is that the accuracy of rifled howitzers becomes so necessary. In order to make a practicable branch up which an assault can be delivered, the masonry at B (fig 31), must be cut away, and owing to the height of the cover at A the fire must be curved to reach a point sufficiently low. Direct fire—*à la plain point*, as the French express it—would strike too high up. Sometimes a work is so constructed that it is necessary to strike a point half-way down the masonry revetment to form a practicable breach. As it is desirable to strike with as much force as possible in breaching, it is evident that where the profile of the work requires the angle of descent of the shell to be considerable, it is necessary

Breach
ing

FIG 31—Profile of Work

to select a spot for the battery at the longest range compatible with accuracy. For, given a certain angle of descent, the longer the trajectory (*ceteris par*) terminating in that angle, the greater will be the remaining velocity. Sometimes the guns of the siege train are employed with an aim in the field to hold certain valuable ground against attack. They are then called guns of position, and are so placed as to command the approaches most effectively, and yet, if possible, to be dragged away at the last moment in case of retreat. They will usually fire shrapnel shell when thus employed.

4 The all-important qualities of field guns (figs 35, 36, 37) are mobility and shrapnel throwing power. They must be able to make long marches rapidly, to change position with celerity, to crush troops and the enemy's artillery with

accurate, well sustained fire at high velocities, and to support rough usage without detriment to their efficiency. They are supplied with shrapnel and common shell, and also shot, of which shrapnel form by far the largest proportion.

5 The mountain train guns are both 7-pounders, they fit most the same shell, but the heavier one uses a 12 oz cartridge, and while 6 ounces is as much as can be fired from the lighter gun.

FIG 35—13 pounds of 8 cwt (section)

one. Both guns are intended for mule transport, one mule taking the gun, another the carriage, and a third the wheel, &c., but at the Cape of Good Hope the heavier 7-pounder is mounted on a light high field-carriage for transport as well as for firing, while in Ashantee the lighter 7-pounders were dragged on a kind of sledge. The lighter gun is tolerably effective for nearly a mile, and the heavier for about a mile and a half. Some jointed guns, proposed by

FIG 36—13 pounds of 8 cwt (front view)

FIG 37—13 pounds of 8 cwt (section of groove)

an artillery officer, are now under trial. They are composed of two pieces screw ed together, and, being carried separately, form a gun of about twice the weight of the ordinary mountain gun. Great increase of power is expected from this method of construction. Mountain guns are principally employed to throw time fuzed shrapnel at troops, and percussion-fuzed common shell into hill works and woods occupied by the enemy.

In Table V the principal sea-service rifled guns are shown. Naval Three kinds of work are performed by them, viz, to place guns on land and mounted forts, to attack unarmoured vessels, and to keep up a fire on troops on shore or on approaching boats. The heavy armour-piercing guns are well provided with common shell, as well as with chilled projectiles, so as to perform the first and second duties, but they have a very small proportion of shrapnel shell, which is intended to be used by them against troops or boats only on emergency. The 7-inch and 61-pounder guns are supposed to be quite sufficient in ordinary cases for the second and third duties, assisted in the third case by the smaller boat guns. All these are well furnished with common shell and shrapnel.

Gun Carriages.—The development which has taken Carriage place of late years in the power of artillery has necessitated corresponding changes in gun carriages. Formerly, every carriage was capable of travelling to some extent, even the heaviest guns were mounted on carriages fitted with trucks, which permitted motion on the rails or on a deck. Later on, sloping traversing platforms were introduced, up which the gun carriage recoiled on firing. Extra means of checking recoil became necessary as the power of the guns grew, compressors, or friction plates, were introduced, and are now only partially superseded by the hydraulic buffer. Mobility of carriage has almost entirely been given up, except for field and mountain artillery. The heavier siege guns travel on platform waggons, not on their firing carriages, and it is possible that the traversing platform and slide principle will extend yet further.

Tables IV and V show the various pieces in the British service are mounted. Differences of detail exist, but the general system is the same for all European

tries. Wrought iron is rapidly supplanting wood in the traction of carriages, and there are signs that it will in art be in great measure superseded by a mild steel. The subject of gun carriages is too long and too complicated to be treated in detail here, but, as guns are of no use

FIG. 38.—9-pounder Field Gun Carriage (elevation).

out carriages from which to fire them, it is necessary to some idea of the chief modes of mounting modern artillery. Figs. 38, 39 show the details of the 9-pounder muzzle-loader carriage. It consists of three parts, the axle, the axle, and the trail. The wheels have oak

FIG. 39.—9-pounder Field Gun Carriage (plan).

and ash felloes, the tire is of wrought iron, the nave pipe box (which holds the end of the axle-tree arm) of brass, and the axle-tree of copper, tin, and zinc. The dish is considerably more than 2 inches in the 5-foot wheel. There is a strut, so that the lowest spoke is nearly vertical, and

FIG. 42.—9-inch Gun Wrought Iron Carriage and Dwarf Platform.

of the gun carriage, ammunition boxes, platform, and axle. In the British service each gun carriage and its platform are drawn by three or four pairs of horses, according to the nature of the piece. The driver of each pair mounts

the tire forms a frustum of a cone, instead of being a cylindrical. The object of this form is to obtain lateral gun carriage strength, especially in travelling on uneven ground. The axle-tree bed is of wrought iron, constituting, with the axle, a beam of box-girder section, the axle-tree forming the bottom. The trail consists of two side brackets, fixed by

FIG. 40.—9-pounder Limber (elevation).

two transoms, two bolts, and the trail piece carrying the trail eye. The brackets are made of plate iron, riveted to a frame of angle iron. The axle carries two seats for gunners; into the trail are fitted the elevating screw and wheel, and the drag shoe with chain hangs below. Fig. 38 shows the gun and carriage in the firing position; when it is desired to move it to any distance exceeding a

FIG. 41.—9-pounder Limber (plan).

few yards, the point of the trail is raised, the limber is brought up, the trail eye is passed over the limber hook and keyed fast. The gun carriage and limber then form a four-wheeled vehicle, and travel as such. Figs. 40, 41 show the limber, which consists of wheels and axle-tree similar to

the near horse; the off wheel horse is between the shafts. In some countries pole draught is preferred.

Fig. 42 shows a 9-inch gun mounted on a wrought iron carriage and dwarf platform. This arrangement may be

Traversing slides

considered typical of all sliding carriages on traversing platforms. The direction of the gun is changed as required by traversing the platform to the right or left, the trucks working on the rails, front and rear, which are usually of wrought iron, laid concentrically on a bed of stone. The level of the traversing platform rises towards the rear, so as to assist in absorbing the work of recoil on firing, and to facilitate running forward again after loading. The recoil is also checked either by a system of friction plates, called a compressor, or by an hydraulic buffer, placed parallel to and between the sides of the traversing platform, so that the carriage on recoil forces a piston into a cylinder containing oil, which escapes, through holes cut through the piston head, into the space round the piston rod, the size of the holes and the amount of the oil regulate the resistance offered to recoil, and enable the gunner to stop the piece at the proper place.

Diving platform cranes

Several kinds of carriages on the "disappearing" principle have from time to time been put forward. In these the gun is exposed to the fire of the enemy only while being aimed and discharged, loading is performed under cover. The Moncrieff carriages are the most successful of this class. In them the force of recoil is stored up and employed to raise the gun from the loading to the firing position. Colonel Moncrieff applies his principle in two ways: the recoil either raises a counter weight or forces a piston into a cylinder, connected by the aid of a fluid, with an already much compressed. The counter weight carriages are used to some extent in coast defence, and the hydro pneumatic carriages are under trial for sea-guns. Plate V gives the details of the former. On a level traversing platform rolls a carriage or "elevator," which places the gun in the required position either for loading or firing. The end of the elevator opposite to that which carries the gun is weighted, so that the recoil causes the elevator to roll to the rear and the gun to descend, at the same time raising the weight, which is retained in the upward position till released after loading, when its descent again raises the gun. Thus the elevator is a lever of the first order working on a shifting fulcrum, the curve (an involute) of the rolling surface being so adjusted that the resistance of the weight gradually increases as the gun recoils, and finally stops it smoothly and without violence. Conversely, by this form the gun is raised to the firing position gradually and without being jolted.

Moncrieff's system

Hydraulic Gun for Guns.—As soon as the weights of ordnance increased so greatly that their services exceeded the power of manual labour, it became necessary to find some substitute. Steam power is always at hand in steam vessels, and it was quickly seen that it was best applied through the medium of water pressure. The simplicity and compactness of hydraulic machinery, the circumstance of its direct action rendering tooled gear unnecessary, and the perfect control it gives over the motion of heavy weights, especially adapt it for the purpose.

Recoil's by hydraulic systems

Plate VI represents the mode in which the system is applied to the working of the 80 ton gun on board H.M.S. "Julius." A circular tank contains two guns placed side by side, and strictly parallel as to line. The hydraulic pressure is conveyed through the trunk A by pipes to the recess in the turret. At B is a piston for raising the gun, this press also absorbs the force vertically given off during recoil on the elevating beam C. D is the gun slide which carries the recoil press G for checking the recoil. This press is supplied with a tank T, up into which the water from the press G must escape through valves V loaded to the required pressure by springs. H is the gun run forward in the firing position, its ammunition is fixed to the end of a piston rod, the head of which enters the press G, when the gun recoils the water in the piston rod, shown by a dotted outline. The ammunition B forces the piston home into the cylinder G, driving the water up into the tank, the trunnions sit snugly along the gun slide horizontally, and the attachment or saddle below the gun slides up the elevating beam C, which is pivoted at the fixed point T, so as to depress the muzzle outside

the port P of the turret R. The gun is then in the loading position. In the meanwhile the turret has been caused to revolve, on the central rollers H, H by hydraulic pressure till the muzzle of the gun is brought opposite the loading apparatus, which is securely housed below deck. The water pressure is then down the ammunition hoist K, which issues a track I, carrying a shell, on the top of which is laid a cartridge, to the loading position M. The sponge N, similarly worked by hydraulic pressure, serves as a rammer also. To perform the work of loading, the sponge is forced home through the base of the gun against the bottom, by contact with which a button on the head is pushed, acting like a push of water, it is thoroughly and visibly driven the base, and it marks the exactest possibility of a burning chamber being struck from the previous round, the sponge is then withdrawn, and the ammunition rammed to M, the sponge now becomes a rammer, thrusts the cartridge into the muzzle of the gun, and is drawn back, the track is raised still higher, the rammer then pushes the projectile into the muzzle, and jams home both cartridge and shell together, a wad previously placed on the head of the rammer is left behind, left in the base in front of the projectile, which is thus prevented from moving forward. An indicator on the rammer shows whether the charge is home. The press B is then put in action to lower the breech, raising the muzzle to the elevation required to send the range of the object to be fired at, the gun is then forward to the firing position E, and the turret is revolved till the gun points at the object. The sighting is not on the gun, but on the turret, the captain of the battery looks through a hole in the roof H, behind the gun, and reads the movement of the turret at the central place, when the line between the turret and the muzzle to the axis of the gun, is directed to the object. The firing may be performed either in the turret air, or by electric cables and wires from a distance.

Plate VII, fig. 2, shows a 100 ton rifled muzzle-loading gun, mounted on barbette on coast defence, and adjusted for hydraulic loading. After being fired the gun is returned round to the position A, where the muzzle is brought opposite the loading apparatus G, which is contained in a recess in the turret D. At the muzzle hoist E issues the ammunition on a track F to the muzzle, a rammer apparatus is constructed on the right of the gun, which is intended to reduce the pressure. The carriage B sits on the platform C, which pivots on P, a tank through which is introduced the hydraulic power for running the gun back and absorbing the recoil.

Many other applications of hydraulic power to gunnery besides those just described are due to Mr G. Lendall of the great Elswick firm. One of the most novel is that adopted in H.M.S. "Ternation," in which 25-ton guns are mounted on the disappearing principle in a turret having no roof and no ports, inside the turret is a turn table carrying the guns by the trunnions on two axes, which are raised by hydraulic power, enabling the gun to fire *en barbette* over the wall of the turret. The recoil brings it down again, and it is placed opposite the loading gun by revolving the turn-table. The general principles are the same as those on which the previously described systems are constituted.

Loading.—This article would be scarcely complete without a reference to the comparative advantages of the muzzle-loading and breech-loading systems. Many have been much impressed with the great superiority of breech-loaders as small loading arms, whether for sporting or military purposes, and have concluded that the same superiority must extend to ordnance constructed on this plan. Others, having seen the difficulty of avoiding complication and accident to the parts in the early breech-loaders, have hastily condemned the whole system. The truth, as is often the case, lies between the two views, as will be seen from the following considerations. The chief points of excellence to be attained by a field gun are—(a) high ratio of power to weight, (b) immunity from injury by its own fire, (c) immunity from injury by the enemy's fire, (d) capability of supporting the accidents of service, (e) rapidity and facility of manipulation, (f) efficiency of projectile. (a) The power of a gun is most conveniently measured by the energy (in foot tons) communicated to the projectile on leaving the muzzle. The following table shows how the latest English and German field guns compare together in this respect. The English guns are muzzle-loaders, the German ones breech-loaders.

TABLE VI

Gun	Nation	Weight	Muzzle velocity	Range	"	Remarks
9	English	12½	1260	119	397	Service guns
10	"	12½	1305	213	348	
11	"	8	1500	220	550	
13	"	7½	1595	181	467	Manufactured
15	"	9	1460	222	493	

lead. The English 9 and 16 pounders at the time of their introduction were the most powerful field guns known, but were after a time beaten by the new German guns, which will in their turn be beaten by the new English piece, the first supply of which was lately issued. Recently a trial was carried out of two field guns made by Sir W. Armstrong & Co. They were precisely similar in all respects, except that one was a breech, the other a muzzle-loader. No difference in their excellence could be detected. Thus it may be considered as certain that the power of a gun is in no way affected by the mere fact of its being a muzzle-loader or a breech-loader. Should, however, the adoption of one system favour an improved construction, or lend itself more readily than the other to the use of improved ammunition, this equally would disprove, and muzzle-loaders should gain a decided advantage in power, which cannot be obtained by its rival, must certainly prevail. It is almost impossible to overstate the importance of high velocity, combined, of course, with efficiency of projectile. In the field it enables the gunner to place the enemy under fire at long ranges, and so to force him to change his formations, and show his hand. It intensifies both the moral and physical effect of shell upon troops. It permits the guns to occupy good positions without the necessity of constant moving to get within range. In entrenchment firing it is, if possible, of still greater importance. Low velocity projectiles fired from field guns are almost harmless against earthworks. They have not sufficient bursting charge to do damage to the work by mere explosion, not impetus enough to cut down the parapets, while the defenders hear the gun and crouch under cover as the shell comes. Thus it is not surprising that all our recent advances have been towards high velocities. Nothing has tended more to this end than the enlargement of the diameter of the powder chamber, which facilitates the profitable consumption of increased charges. This improvement is found to act differently on the two systems of loading. A chambered muzzle-loader requires an expanding cartridge (in field guns), a chambered breech-loader requires a breech-closing apparatus of increased size and weight. Supposing a satisfactory expanding cartridge to be devised, the muzzle-loader gains in ratio of power to weight. If this be found impracticable, the breech-loader secures an important advantage in this respect. Experiments are still in progress, and it would be premature to pronounce definitely in favour of either at present, especially as some fresh discovery or new explosive may at any moment confer preponderance on either system. (b) In the Russo-German War of 1870, a large number of old pattern double-wedge breech-loaders became unserviceable by their own fire. This difficulty appears to have been quite overcome in the newer patterns of Krupp field guns by the adoption of the cylinder-pistonic wedge, with Broadwell ring and steel facing-plate. It would probably be incorrect to affirm that a breech-loader has quite as great immunity from injury by its own fire as a muzzle-loader, since no joint, however well contrived, can be as strong as the solid-ended steel tube forming the breech of the latter. But, putting mathematical certainty of security out of the question, it may now be accepted that practically field guns can be made as

safe and enduring on one system as on the other. (c) As regards immunity from injury by the enemy's fire, the muzzle-loader has a decided advantage. It is difficult to estimate the real value of this advantage, depending as it does partly on the manner in which artillery is employed, and partly on the doctrine of chances. During the Russo-Turkish War of 1877-78 but few guns were placed *hors de combat* by the enemy's fire. In such cases as did occur, the injuries were nearly always such as would not have affected muzzle loaders. The wedge handles were usually bent up by the action of percussion fuse shell jamming the wedges. The Russian field guns were generally of a feeble class, the proportion of entrenchment fighting was unusually large, and in the field the Turkish artillery habitually fired at long ranges. It may therefore be fairly concluded that the number of guns injured by the enemy's fire was not so great as to render the superior invulnerability of muzzle-loaders of much importance. These conditions will probably be reversed in any great war in which England may take part, and hence the advantage gained by muzzle-loaders in immunity from damage by hostile fire must be carefully borne in mind in comparing the two systems of loading. (d) In capability of supporting the accidents of service, there is not much to choose between the two rivals. The breech-loader is more liable to injury from being struck and exposes more parts and finer fittings to the action of the weather. On the other hand, it is easier to clean, and the officer can better see that it is clean. The jamming of projectiles in the bore when ramming home, which sometimes occurs with muzzle-loaders, is impossible with breech-loaders. This defect, it is hoped, has been overcome in the new English field gun. The preservation of breech-loaders, especially in mountainous countries, necessitates a profuse expenditure of oil and grease. (e) In comparing the rapidly and facility of manipulation of the two methods of loading, it is necessary to consider the circumstances under which the guns are employed. Suppose a horsed battery of guns to gallop to an open spot whence they command a body of hostile troops in motion. Coming into action, the gunners load and fire as rapidly as accuracy will permit, unhampered by parapets. It is evidently of great importance to throw as many projectiles as possible against the enemy. Here the muzzle loader will have some advantages. With full detachments in the open it takes rather less time to load, aim, and fire a muzzle-loading field gun than a breech-loading one. The reason of this is that with the former the man laying the piece can manipulate the sight and usually take aim while the loading is being performed, while, when the projectile and cartridge are thrust in from behind, he has to wait till the loading is done before he can get to the sight. There is no practical difference in the time occupied by the actual loading. In one case, the cartridge and shell are rammed down a long distance together, in the other, first the shell is put in a short distance, and afterwards the cartridge, and the wedge has also to be withdrawn and replaced. Next, suppose a commanding position to have been selected for a battery, and a light entrenchment to have been thrown up, over which the guns fire. Here the muzzle loader will lose the advantage gained when firing in the open, as it must be loaded before being run up to the parapet, and aimed afterwards. Both natures of gun recoil, and it makes no difference in time whether the ammunition be thrust home when the gun is back at the recoil position, or after it is run up to the breech-loader and the muzzle-loader stand upon equal terms. Thirdly, suppose—a rare case with field guns—that firing with reduced charges is required, that shell are being lobbed from behind a parapet at high angles into a work. Here we shall have little recoil, probably not enough to permit loading at the muzzle without the gun

being run back by hand. Loading at the breech will, however, be perfectly ample. In this case the breech-loader gains a very decided advantage over the muzzle-loader, since not only does it not require to be run back, but it has to be run up merely a very short distance. To this the advocate of muzzle-loading will probably reply that shells are lobbed with low velocities into works only at considerable intervals of time, that rapidity is therefore of no use, and that the advantage claimed is worthless. No doubt there is truth in this argument, but suppose the action of reduced charges on the gun to be imitated by the introduction of a brake which shall check the recoil within a short space, even when the gun is firing rapidly with high velocity, then the breech loader behind entrenchments gains a distinct advantage. The German guns are supplied with powerful but clumsy brakes, more for travelling purposes than for firing, and it is doubtful how far they answer for the latter object. In the British service it has not been thought important to check recoil, since a certain amount of it has been necessary for loading behind parapets, but trials have been made of brakes, &c., for the purpose of preventing guns from running backwards down a reverse slope when fired from the crest of a hill, or, more generally, for checking excessive recoil. Up to the present time (1879) no great success has attended these efforts, nor does it appear feasible to abolish recoil altogether by sinking the wheels in a ditch, since the strain on the carriage would then be much increased. There is no doubt the question offers grave difficulties, especially as lightness is such an important feature in the construction of field gun carriages. As yet, then, the reduction or checking of recoil behind a parapet contains but a problematical superiority on breech loaders, and cannot be held to counterbalance the advantage gained by muzzle loaders in the open. (7) In the older pattern guns of both systems, where studs and windage were fitted against lead coating and no windage, the muzzle-loading projectile was able to take a better time fuse than could be used in the breech-loader, but it did not possess the same accuracy of shooting. Since the introduction of the poly-groove system, in which rotation is given and windage sealed by a copper-flanged ring or disc at the base of the shell, the muzzle-loading projectile has lost the advantage of being able to use the simpler time-fuse, but has gained in several important respects. The breech-loading shell has also been improved by the substitution of two copper wires for the lead coating, but is probably inferior to the new muzzle-loading projectile, which, however, can be used equally well for breech-loaders. It may be said therefore that the systems are equal in respect to efficiency of projectile.

Thus, then, taking the six qualities named as chief excellences to be sought for in field artillery, it appears that in four of them there is practically little or no advantage gained by either system over the other, while, in the two remaining qualities, the muzzle-loader has slightly the best of it. On the whole it seems therefore that, at the present moment, the balance of evidence is in favour of muzzle-loading for field guns.

For large
guns—

In comparing the advantages of the rival methods of loading siege guns, the entirely different character of the two classes of pieces composing a train at once forces itself on the attention. One class consists of long guns, projecting far over a parapet, and usually fired at low elevations with heavy charges, the other of short guns, usually fired at high elevations with low charges, the muzzle or recoil coming well within the emplacement. The German use long and short 15 centimetre guns, both breech-loaders, and both throwing shell of the same weight. The long gun, fired with heavy charges, weighs three times as much as the short gun, which is fired with light charges. Supposing

the dimensions of the short gun were increased, the proportions remaining unchanged, till its weight equalled that of the long gun, then it would be able to fire shell of three times the weight. This is what is actually being done in the British service. Now all these heavy pieces, firing either heavy powder charges or heavy shell, require very strong and consequently very heavy carriages to bear the recoil, and it is found convenient to transport the guns on comparatively light platform waggons apart from their firing carriages. Hence there is no longer any necessity for constructing firing carriages with a view to travelling purposes, and it is probable that travelling slides will be introduced for all heavy siege pieces. It is not requisite to insist at length a comparison of the various qualities desired for siege guns. Rapidity is very rarely of importance with them, they are always fired under cover, and it may be at once assumed that, as far as power and endurance go, the two systems are practically equal. A fresh set of conditions comes into play the projectiles are heavy, and convenience of loading, combined with safety to the gunners from the enemy's fire, should now be considered. As these points are connected with the form of carriage employed, it was necessary to call to mind in comparing breech with muzzle loading, that slides are likely to take the place of travelling carriages. When long guns are fired, in order to permit loading at the muzzle, it is necessary that the recoil should be great, and the emplacement deep. Many devices, such as flexible rope hammets, jointed staves, &c., have been tried, but have not proved perfectly successful in overcoming this difficulty. Breech-loading here has a considerable advantage. Long guns are fired at low angles of elevation, and no difficulty therefore is experienced in thrusting the projectile home from behind in a nearly horizontal bore. High velocity is required, and the breech-loading system lends itself readily to enlargement of the powder chamber, without necessitating the complications of an expanding cartridge. If slides are used the hydraulic buffer checks the recoil at once, on the other hand, the parapet affords rather better protection to men standing close to it as the muzzle than to men standing a little way off as the breech. These conditions are reversed with the short pieces. The rammer is shot, and no great recoil is necessary to permit loading at the muzzle. The elevation is high, and it is much easier to drop a shell in from the front than to thrust it up from behind. Indeed this cannot usually be done, and a breech-loader has to be brought nearly horizontal for loading. High velocity is never required, and enlargement of powder chamber is not wanted. The men are in the most sheltered position at the muzzle. If these views be admitted as correct, it seems clear that the long pieces of a siege train should be breech-loaders, and the short ones muzzle-loaders. To this it may be objected that uniformity would be sacrificed by such a combination. There is not much in this objection. The mere fact of two guns being loaded in different ways is surely of little consequence, and can easily be grasped by the dullest gunner. It is done every practice day on board ship, where the old pattern Armstrong vent-piece breech-loaders are combined with modern muzzle-loaders. As regards the stores, a long and a short gun of the same weight would not under any circumstances fire the same ammunition, and even in cases where a heavy long gun is associated with a light short one having the same diameter of bore, as in the case of the German 15-centimetre pieces, there is no reason why the same projectile should not be used for both; if desired, that is, the new smooth muzzle-loading shell, with a gas-check on the base, would answer for both.

The question of breech-loading or muzzle-loading is obviously not only complicated, but is liable to alteration in its conditions with every advance made in the science of

tageous terms, and now India supplies vast quantities of gunnies to Europe, Egypt, Ceylon, the Malay Archipelago, China, and the United States. In America alone it is computed that the annual average output of cotton is 8,500,000 bales, each bale requiring 6 yards of wrapping material, and of this one third at least is supplied in gunny cloth. In 1872-73 6,105,575 gunnies and 64,347 pieces were exported from India, whilst in 1876-77, during a period of eleven months, 30,110,616 gunny bags and 5,262,835 yards of gunny cloth were exported to foreign countries. These figures do not include what is sent coastwise or what is used for packing exported Indian produce

Bombay too has machinery for weaving jute, but has not as yet done much to compete with Bengal, and indeed there appears little hope for Bombay unless large quantities of jute can be made to grow on the spot, since, apart from the cost of carriage, the juices in the jute plant, as in many other plants, become insensitised by dying, and therefore require operating upon whilst perfectly fresh, being attended after treatment with more difficulty in manipulation and a less output of fibre.

The excellent gunny bags sent to England are often used for repacking for exportation, and large quantities find their way to paper mills.

GUNPOWDER

Historical sketch

UPON the great importance of the invention of gunpowder it is needless to dwell. Not only has it revolutionized the art of war, and given the forces of civilization a vast advantage over mere numbers and savage valour, but we may even urge, paradoxical though it appears, that the very improvements by which modern science has rendered military machines more deadly tend to make war far more expensive, and therefore to prevent its being so frequently or so rashly undertaken as of old. Besides such indirect services to civilization, gunpowder has been and is of great use in the arts of peace, although of late years to a certain extent superseded by more potent explosive agents. Such being the case, it is not a little remarkable that the discovery of gunpowder should be veiled in uncertainty, although this very obscurity seems proof of its great antiquity. It is, however, certain that it was not invented, as has been often stated, by the German monk Bertholdus Schwartz, about 1320, although Wilkinson, in his *Engineer of War*, considers Schwartz may have suggested the use of a mortar, since the form as also the name of this piece of ordnance may well have been due to some accident in the laboratory. Roger Bacon, who was born in 1214, refers, *circa* 1267, to an explosive mixture of the nature of gunpowder as known before his time, as being employed for purposes of diversion, and as producing a noise like thunder, and flashes like lightning, he even suggests its application to military purposes, and indulges in the supposition that some such composition might have been employed by Gideon to destroy the Midianites (Judges vii). He elsewhere writes—"Ecce ludiorum pueri quod fit in multis mundi partibus, sicut, ut instrumento fecio ad quantatem pollicis humani, ex hoc violentia salis, qui salpêtre vocatur, tam horribilis sonus aueritur in ruptura tam modice pergruens, quod foris tonitru rugitum et coruscationem maximam sui luminis jubeat evocari" (see preface to Jebb's edition of Bacon's *Opus Majus*). In the above passage salpêtre is alone referred to as the violently explosive substance, but Bacon was well aware of the fact that salpêtre of itself will not explode, for in his previously written treatise, *De Secretis Operibus Artis et Naturæ et de Nobilitate Magiæ*, he says "that from salpêtre and other ingredients we are able to make a fire that shall burn at any distance we please." In chap. xi of the same work these other ingredients are veiled in the diagnosis of an anagram "Sic tamen salis petre sua nops cum vitre et sulphuris, et sic facies tonitruum et coruscationem, a sciss artificum," the unmeaning words in italics have been translated as *carbomum pulvere* in his work on gunnery (1717), and Dutens Robins, in his *Essay into the Origin of Discoveries attributed to the Moderns* suggest that Bacon may have derived his knowledge from the MS of Marcus Græcæ, preserved in the National Library in Paris, entitled "Incipit Liber Ignium a Marco Græco prescriptus, cujus virtus et efficacia est ad

comburendum hostes, tam in mari, quam in terra." Marcus Græcæ, who lived about the end of the 8th century, was therefore not ignorant of the military uses to which the composition might be put, among other modes of launching fire upon an enemy he gives one to the following effect— one pound of live sulphur, two of charcoal of willow, and six of salpêtre, reduced to a fine powder in a marble mortar and mixed together, a certain quantity is to be put into a long, narrow, and well cemented cover, and then discharged into the air. This is evidently the description of a rocket. It has also been suggested that Bacon may have learnt the secret in Spain, in which country he is known to have travelled, and whose Moorish masters were then far in advance of the rest of Europe in science and literature. Albertus Magnus, in his treatise *De Mirabilibus Mundi*, repeats almost word for word several receipts in the work of Marcus Græcæ, also, an epistle by Ferrarius, a Spanish monk, and a contemporary of Bacon, which is preserved in the Bodleian Library at Oxford, gives receipts for Greek fire, rockets, and "thunder." There is a treatise on gunpowder in the library of the Escorial, written about 1250, which appears to describe both rockets and shells, the Arabians are, from this and other authorities, supposed to have enclosed combustible or explosive gun positions in hollow globes of iron, which were discharged upon the foe either by hand, like the modern grenade, or from the warlike machines then in use, it has also been stated that towards the close of the 13th century they projected small balls from tubes carried in the hand, or attached to the end of a lance, and only used at close quarters, being in fact hand guns. Rockets were employed during the reign of the Greek emperor Leo, about 850, and indeed seem to have been known in India from time immemorial, some of them having been made of great size.

The gloom of the dark ages precludes further attempt to trace back the history of gunpowder with any certainty, but Mr. Dutens, in the work before quoted, advances many passages from classical authors in support of his view that a composition of the nature of gunpowder was not unknown to the ancients, as, for example, the story of Salomonus, king of Elus, who, according to Virgil (*Æneid*, vi. 585), for his audacity in attempting to imitate thunder and lightning, was slain by Jupiter. Mr. Dutens considers he may have fallen a victim to his own experiments. Eustathius, a commentator on Homer, speaks of him as being so skilled in mechanics that he constructed machines to imitate thunder (Eustathius ad *Odyssey*, l. 234, p. 1682, l. 1, see also Hyginus, *Fabulæ*, vi. 650, Valerius Flaccus, lib. i. 669). It is also narrated of Caligula by Dion Cassius (*Hist. Rom.*, "Caligula," p. 662) that he had machines which imitated thunder and lightning, and emitted stones. See also Johannes Antiochus, *Chronicon apud Pappum* *Valens*, Paris, 1604, p. 804.

According to Themistius (*Orat.*, xxvii p. 337) the Babylonians had similar machines. Philostratus, in his life of Apollonius Tyaneus (lib. ii cap. 14), written about 200 A.D., relates of a people of India, dwelling between the Hyphasis and the Ganges, whose country Alexander never entered. "Thor cries he could never have taken, though he had led a thousand as brave as Achilles, or three thousand such as Ajax, to the assault, for they come not out to the field to fight those who attack them, but these holy men, beloved by the gods, overthrow their enemies with tempests and thunderbolts shot from their walls."

From the mention by Vitruvius, and in Plutarch's life of Mariellus, that one of his machines threw large stones with great noise, it has been thought that Archimedes used some explosive composition in the defence of Syracuse.

The most ancient reference of all is in the Genko code of Iwya (Halhed's translation), supposed by some authorities to be coeval with Moses. It runs thus: "The magistrates shall not make war with any decent machine, or with poisoned weapons, or with cannon and guns, or any kind of firearms." The translator remarks that this passage may "serve to remove the suspicion, long since deemed absurd, that Alexander the Great did absolutely meet with some weapons of that kind in India, as a passage from Quintus Curtius seems to ascertain." The word translated firearms is literally a weapon of fire, and one species of it has been described as a dart or arrow tipped with fire and discharged from a barrel, so that the reference may not be to any propelling agent, but merely to some combustible or incendiary composition, of the nature of the so-called Greek fire.

It is almost certain that those authors who assert that the Arabians used gunpowder at the siege of Mecca, 680 A.D., having derived their knowledge of it from India or China, confound gunpowder with this Greek fire, which seems to have been the generic name given to several different combustible mixtures, although Arabian writers speak of them as Chinese fires. Greek fire was introduced into Constantinople from the East about the year 673, it was discharged upon the enemy by means of various engines of war, or in smaller quantities attached to arrows or darts. The Saracens used it against the Crusaders at Marmourin, in his *History of the Crusades*, describes its effects, and Joinville, who was an eye-witness, says "it was thrown from a petrary, and came forward as large as a barrel of vinegar, with a tail of fire as big as a great sword, making a noise like thunder, and seeming like a dragon flying in the air, the light it gave out from the great quantity of fire rendered the camp as bright as day, and such was the terror it occasioned among the commanders in the army of St. Louis that Gautier de Chauli, an experienced and valiant knight, advised that, as often as it was thrown, they should prostrate themselves upon their elbows and knees, and beseech the Lord to deliver them from that danger against which he alone could protect them." However, its actual destructive effect seems to have been very inadequate to the terror it occasioned. From the account of Geoffrey de Vinesauf, sand and earth, but especially vinegar, appear to have been considered the best extinguishers, water would not put it out. One description of this wildfire was composed of resin, sulphur, naphtha, and probably saltpetre. Bacon states that religious scruples hindered European nations from adopting Greek fire, but if so, they seem to have been gradually overcome, for its use is mentioned by various writers, Anna Comena, Pire Daniel, and Flossart among them. Similar scruples no doubt considerably retarded the introduction of gunpowder, and the fear that its adoption would prove fatal to all knightly gallantry also caused it to be regarded with aversion. Endow, the famous Persian poet, describes in

his writings what were doubtless the effects of rockets and wildfire discharged upon the enemy, but he ascribes the whole to magic.

The researches of all authorities seem to point to the Far East as the birthplace of an explosive mixture of origin the nature of gunpowder, it was used there from time immemorial, although doubtless its application as a propelling agent is of far later date. In all probability, the germ of the science of explosives lay in the accidental discovery of the peculiar properties of the nitre so plentifully found mixed with the soil upon the vast plains of India and China. By means of the charred embers of wood-fires, used for cooking, the two most active ingredients of gunpowder might easily be brought into contact, and, under the action of heat, more or less deflagration would ensue, in fact, the accidental dropping of some of the crude sulphates into the coals would show its remarkable power of supporting and accelerating combustion. The combination of saltpetre and charcoal in a more or less powerful mixture can therefore be easily conceived, the sulphur being an after addition, and not necessary to cause explosion. Our present gunpowder is only the improvement and perfection of such a mixture. Saltpetre was early known as "Chinese snow," and some have supposed the use of gunpowder in cannon to have been known in China very soon after, if not before, the Christian era. But this seems to be an error, for Colonel Anderson, C.B., in his book on gunpowder (London, 1862), quotes a conversation held by John Bell of Antwerp, who visited Peking in 1721, with the emperor's general of artillery, to the effect that from their records it had been used in fireworks, &c., for about 2000 years, but that its application to the propulsion of shot was a late introduction. Some of their compositions had such names as "devouring fire," "earth thunder," &c. The *Invitation of Tamer*, written about the middle of the 14th century, contains no mention of cannon or gunpowder, although full particulars are given of the equipment of his troops, it is, however, related that when Timur engaged the army of Mahmud under the walls of Delhi, men loaded wildfire and fired rockets in every direction. In this connection it may be noted that, while the use of rockets was of very old date in India, the names given to pieces of artillery under the rule of Baber and the Mogul conquests of Hindustan almost invariably point to a European, or at least to a Turkish origin. It is also well authenticated that Akbar and Aurangzeb had Englishmen and other Europeans in their service to teach the art of gunnery. The analysis of the gunpowder made by the Chinese in the present day shows a composition almost identical with that employed in Europe, which has only been altered at certain centuries of experience, so that, in all probability, they have corrected their earlier formula from Western sources.

Whatever obscurity may hang over the early history of gunpowder, it seems most probable that its employment as a propelling agent originated among the Moors or Saracens,—whose civilization for several centuries contrasted forcibly with the intellectual darkness of Christendom,—and from them spread eastward, as well as northward into Europe. Condé (*Le Dom Arabe en Espagne*) states that Ismail Ben Feraz, king of Grenada, who in 1325 besieged Baza, had among his machines "some cast-iron globes of fire with resounding thunders and lightnings resembling those of the resounding tempest, all these machines caused fearful injuries to the walls and towers of the city." The first reliable contemporary document relative to the use of gunpowder in Europe, a document still in existence, bears date 11th February 1326, it gives authority to the prior, the gonfalonier, and council of twelve of Florence to appoint persons to superintend the manufacture of cannons

of brass, and iron balls, for the defence of the commune, camps, and territory of the republic.

If the testimony of John Barbo, a witness of Aberdeen, who wrote in 1775, it is to be believed, cannon, which he calls "cannons of war," were employed during the invasion of Scotland by Edward III in 1327, but they are not mentioned in the accounts of the expenses of this war preserved in the record office. An indenture, first published by Sir N. H. Nicolas in his *Hist. Royal Navy* (London, 1847), and since by Lieut.-Colonel H. Blackebury (*Proceedings of A. Institution*, 1865), stated to be of 19 Edward III, 1338, contains several references to small cannon as among the stores of the tower, and also mentions "un petit baril de gunpowder le quintillon." If authentic, this is certainly the first distinct mention of gunpowder in Great Britain we now possess, but doubts have since been thrown upon the date of this MS. It, however, seems certain, from a contemporary document in the National Library in Paris, that, in this same year 1338, there existed in the main arsenal at Rouen, an iron weapon, called "petit de fer," for propelling bolts, together with some saltpetre and sulphur to make powder for the same, at this period the ingredients were usually kept separate, and mixed when required. From the year 1345, 19 Edward III, we have, preserved in the Record Office, reliable accounts of the purchase of ingredients needed for the fabrication of gunpowder, and of the shipping of cannon for France. In 1316 Edward III ordered all the saltpetre and sulphur that could be found to be brought up for him, but the quantities obtained were very small. Whether it be true or not that cannon were used by the English at Crécy in that year belongs rather to the question of the employment of artillery in the field, it has been maintained that such was the case by Napoleon III (*Études sur la passé et l'avenir de l'Artillerie*). It may be noted that Petrarch, about the year 1344, in his dialogues *De remediis utriusque fortune*, speaks of "brass globes cast forth by the force of flame with a horrible sound of thunder" as having become as common as any other kind of weapon.

In the year 1377, being the first of Richard II, Thomas Norbury was ordered to buy, amongst other munitions, sulphur, saltpetre, and charcoal to be sent to the castle of Brest. In 1414 Henry V ordered that no gunpowder should be taken out of the kingdom without special licence, in the same year this monarch also ordered twenty pipes of powder made of willow charcoal, and various other articles for the use of the gins.

It was not, however, until the reign of Elizabeth that the manufacture of gunpowder can be said to have been established in England. The greater portion required had been previously imported from abroad, and the trade had been an open one, but the threatening attitude of Spain compelled the Government to provide more efficient means of defence, and patents were issued by the crown for the manufacture of gunpowder, constituting it a monopoly. Early in this reign also, saltpetre began to be artificially produced in England, but the quantity so obtained formed a very small proportion of the supply needed, the remainder being brought from various parts of the Continent, and from Barbary. Again, in 1623, nominally in order to prevent the sale of weak or defective powder, a proclamation was issued by James I, prohibiting its manufacture, as well as that of saltpetre, except under the king's commission, and directing that all gunpowder should be proved and marked by the sworn proof-master. A little later, in 1628, the East India Company had commenced the importation of saltpetre, and had also erected powder works in Surrey. Their renewed charter in 1693 contained a clause providing that 500 tons of saltpetre were to be furnished to the ordnance annually, and from this time forward we hear of

no difficulty, at least in England, of obtaining the chief ingredient of gunpowder, although on the Continent great attention has been paid to its artificial production, this was especially the case in France during the reign of Napoleon I, when the supremacy of Great Britain at sea for many years prevented the importation of saltpetre by her enemies.

About the year 1590, George Evelyn, grandfather of the celebrated John Evelyn of Wootton, received the royal licence to set up powder mills at Long Ditton and Godstone, the Evelyns are said to have brought the art from Holland. The works at Faversham, afterwards for so many years the Government gunpowder factory, date from Elizabeth's reign, but were then of secondary importance to those at Godstone. There seems reason, however, to suppose that powder mills existed at Waltham Abbey so far back as 1661, for in that year we find John Thomworth of Waltham in treaty, on behalf of Queen Elizabeth, for the purchase of saltpetre, sulphur, and staves for barrels. Fuller also refers (*English Worthies*, 1338) to the powder mills at Waltham Abbey, of which place he was appointed vicar in 1641. In 1787 they were sold to the crown by John Walton, and incorporated under the superintendence of the famous Sir William Congreve. The old royal factory at Faversham was given up after the peace of 1815, being first let and afterwards sold to the well-known firm of Messrs John Hull & Son, a third Government factory at Ballyshannon, as disposed of, a few years later. The Waltham Abbey works have been greatly enlarged of recent years, and no expense has been spared to render them, by the introduction of new and improved machinery, the most complete as well as the safest in the world. It is impossible to describe in detail the various improvements which have been made in the manufacture of gunpowder, but the most important will be briefly stated when describing the successive processes to which the ingredients are subjected.

THE INGREDIENTS AND THEIR ACTION

The objects to be attained in the production of an explosive agent for artillery and small arms are—(1) the maximum of propelling force, (2) the minimum of internal pressure in the bore of gun, (3) uniformity of action, (4) freedom from fouling, especially in small arm powder, (5) durability, i.e., power to bear transport and keep well in store. Of all explosive substances at present known, gunpowder alone can be said to fulfil the first three conditions. Its advantages may be summed up as follows—(1) the rate of combustion of gunpowder is gradual compared with that of most other explosives, and, both by adjusting the proportions of the ingredients and varying the mechanical processes of manufacture, its explosive powers can be modified so as to suit every description of weapon, (2) the ingredients are easily procured, and are comparatively cheap, (3) with proper precautions, it is comparatively safe in manufacture, in store, and in transport; it also keeps well in a moderately dry atmosphere.

The earliest gunpowder used in cannon in Europe consisted of equal parts of saltpetre, charcoal, and sulphur, ground up and mixed together as required, and must have proved a mixture far inferior in strength to that given in the MS of Marcus Græcæ. To account for the use of such a very weak composition long after better proportions had been ascertained, it must be remembered that the earliest cannon were composed of iron staves roughly hooped together, and tubes of thin iron, or even of wood or leather, with rope coiled round them, were sometimes used. Indeed the effective application of gunpowder as a propelling agent involves a whole series of inventions, and it was doubtless chiefly owing to the backward state of mechanical science during the Middle Ages that such weak powders were employed. The slow growth of artillery science in Europe

Advances
of types
of gun-
powder

for five centuries, and its rapid development in very recent years, are facts which support this assumption. Even about 1410 the proportions were still but 3 saltpetre, 2 sulphur, and 2 charcoal. The relative amount of saltpetre was gradually increased, and Tartaglia (*Queste e Inventioni diverse*, Venice, 1546) mentions twenty-three various compositions as having been used at different times, the gunpowders of his days were—

	Saltpetre	Charcoal	Sulphur
Cannon powder	4	1	7
Musket " "	48	3	7
" "	18	3	2

It is remarkable that Robins states the above proportions to have been very nearly those of his own day (1742), for there is a great deficiency of saltpetre in the cannon powder, and a considerable excess in that for muskets, compared with the relative quantities now employed in England. For a long period of time it was the custom for the fine grain or musket powder to contain a larger proportion of saltpetre than that for cannon, and, again, the amount of nitre was relatively reduced as the piece of ordnance became heavier, doubtless with the view of obtaining a slower burning powder for large charges. However, we find that by the latter part of the last century, what was called "common war powder" was almost universally composed of 6 saltpetre, 1 charcoal, and 1 sulphur, and these are the proportions still in use by many Continental nations (*D'Arçon On Gunpowder*, translated by Capt Thompson, R.A., London, 1787).

So far back as the 16th century, Baptista Porta is said to have arrived at the proportions now used in France, which, however, was certainly not adopted until a comparatively recent period. Exhaustive experiments have also been carried out in that country by Besançon, the Committee of Public Safety, Chaptal, and Proust, who fixed upon percentages of saltpetre varying from 76 to 80, of charcoal from 13 to 16, and sulphur from 5 to 9. These may seem to give rather a wide margin, but this will surprise no one who is acquainted with the great differences in results given by comparatively slight variations in the conditions of experiment, with powder of the same composition. In the British Government service but one scale of proportions has been employed for many years, and the very extensive trials of the "Committee on explosives" have shown that there is no good reason to depart from that scale, for they have conclusively demonstrated that the variations in the mechanical and physical properties of gunpowder, produced by the processes of manufacture, exert even more influence upon its action than a comparatively considerable difference in composition, thus does not, however, apply to the small charges used in firearms. It will be seen, moreover, that one of the three ingredients—charcoal—can be so varied in quality as very materially to affect the results.

The following table gives the percentage composition of gunpowder as now made in different countries for military purposes—

	Saltpetre	Charcoal	Sulphur
England, Royal Gunpowder Factory,	76	15	10
France	75	12.5	12.5
Germany	76	14	10
Austria	76	14	10
Russia	76	15	10
Belgium	75	12.5	12.5
Spain	76	15	10
Italy	75	12.5	12.5
United States	75	12.5	12.5

The proportions of the ingredients in English commercial gunpowders vary considerably according to the market for which they are intended. The best sporting powders

have about the same composition as those made by Government. Whatever discrepancy is the chief object in view the quantity of nitre is diminished, and the other two components relatively increased. Some of the powder for the African trade, commonly called "nigger powder," does not contain much more than 50 per cent of saltpetre, while other kinds are nearly as bad. Blasting powder contains a low proportion of saltpetre, from 60 to 62 per cent, but, although this reduction may originally have been made in order to manufacture a cheaper article, yet it is also the most effective for the object desired in many cases, which is to remove large masses of earth or soft rock, and this can best be done by using a comparatively weak or slow-burning powder. The element of time is here of great importance, a very quick burning or violent explosive would not displace such large masses of a soft material, although the local effect would be more destructive (see *BLASTING AND EXPLOSIVES*).

Before proceeding further, it will be as well briefly to consider the properties of the three ingredients of which gunpowder is composed, and the part played by each.

Saltpetre, or nitrate of potash (KNO_3), occurs as a Saltpetre natural production on or near the surface of the earth in several warm climates, especially the plains of India and China. When it arrives in England, it has only been partially separated from the earthy and foreign saline matters with which it was combined when formed, and is quite unfit for the manufacture of gunpowder, the salts of sodium especially, from their property of absorbing moisture, are most injurious. In this state the saltpetre is known as "rough" nitre, the impurities commonly present being the chlorides of potassium and sodium, and the sulphates of potash, soda, and lime, together with sand and organic matter, they do not usually exceed 5 lb per cwt, the exact proportion of impurities in any sample being termed the "refraction" of the saltpetre, and allowed for in the price. The nitrate of soda, called "cubical nitre" or Chili saltpetre, which is found abundantly in South America, although chemically adapted to supply the place of potassium nitrate, cannot be employed in the manufacture of gunpowder, owing to its very deliquescent properties. This salt is, however, largely converted into saltpetre by the action of chloride of potassium. In France and Germany, also, nitre is produced artificially (see *SALTPETRE*).

Saltpetre, which is a compound of 64 parts of nitric acid and 46 of potash, acts as a magazine of oxygen in a solid form, one volume of saltpetre containing as much oxygen as about 3000 volumes of atmosphere in air. This oxygen, with which it readily parts when raised to a certain temperature, combines violently with the carbon to form carbonic acid and a proportion of carbonic oxide, these with free nitrogen constitute the chief gaseous products of combustion. The potassium is found combined in the solid residue.

Wood charcoal is the charred woody fibre or residue which remains after the liquid and more volatile parts have been driven off by destructive distillation. The object of charring wood is the removal of moisture, and, which is of great importance, the expulsion of those matters which become volatile before they are burned, and which would absorb a large amount of heat. It may be charred in the ordinary way in pits, but the usual mode of preparing charcoal for gunpowder is by heating it in large iron cylinders or retorts, as hereafter described. By this latter method, the operation is performed with more uniformity and economy, and the charcoal kept more free from particles of gutta serena matter. Charcoal is best fitted for the manufacture of gunpowder when prepared from light spongy wood, containing a very small proportion of mineral substances; it should be sound, and of not much more than ten

years' growth. The quality of the charcoal exercises the greatest influence upon the rate of combustion, so that both the description of wood used and the mode of burning are of the utmost importance.

By a series of experiments first made by Proust, and since repeated by English chemists, it has been found that 12 grains of various charcoals, mixed with 60 grains of saltpetre, give the following average volumes of gas—

	Cubic inches
Dogwood (<i>Rhamnus Frangula</i>)	82
Willow (<i>Salix alba</i>)	77
Alder	74
Filbert	72
Fir, chestnut, hazel	69
Overkilled willow charcoal	68

The production of the strongest powder does not depend alone upon the evolution of the largest volume of gas, but the above table is of interest since the three descriptions of wood which head the list have long been considered by universal consent as the best adapted for the manufacture of charcoal for gunpowder. Dogwood (so called, but in reality it is elder-buckthorn, *Rhamnus Frangula*, the French *hou daine*) is an underwood of slow growth, usually obtained from Sussex, Belgium, or Prussia; it is cut about an inch in diameter, and packed in bundles 6 foot long. This wood is now used, both in England and on the Continent, for all military small arm powders, as well as the best descriptions of sporting gunpowder. It has been found, moreover, that cannon powders made from dogwood charcoal are, other things being equal, much more violent in action than those manufactured with willow or elder charcoal. Accidents with powder made from dogwood charcoal have usually proved more destructive than those made with any other description. Alder and willow charcoal is used for making gunpowders for field and heavy ordnance, as well as for the commoner kinds of commercial powders; these woods are obtained from various parts of England, and should measure about 4 inches in diameter. The willow used is the *Salix alba*, one of the softest and lightest of English woods, white in colour, and of very rapid growth, the pith is circular, and tolerably large. Alder is considerably harder and denser in texture, and of slower growth; its colour is reddish yellow, and the small pith triangular or key-hole-shaped in section. Dogwood has a very large pith in proportion to its size, circular, and of a red colour, which is preserved even after the wood is converted into charcoal.

The temperature at which the wood is charred exercises the most powerful influence upon the inflammability of the charcoal, and consequently upon the "explosiveness," or rate of combustion, of the gunpowder made from it. The higher the temperature the larger the proportion of hydrogen and oxygen expelled, and the nearer the approach of the charcoal to pure carbon; at the same time, it becomes more dense and incombustible, and the gunpowder made from it is comparatively slow in action, and gives a low initial velocity. Charcoal prepared at a low temperature is softer and more inflammable, and contains more volatile constituents; it makes a quicker burning powder, giving a higher velocity to the projectile, but also producing more stain or pressure upon the metal of the gun. The chief defect, however, of this "black-burnt" charcoal, or *charbon roux*, as it is called from its reddish-brown colour, is its property of absorbing moisture more readily than denser charcoal; the powder manufactured from it is consequently more hygroscopic, and therefore more liable to deteriorate in strength from the effects of damp than that made with a more highly burnt charcoal. To show the great difference in inflammability caused by burning at low and high temperatures respectively, it may be stated that charcoal prepared at 500° Fahr. readily ignites at about 640°, while, if burnt at 1800° Fahr., nearly double the heat previously mentioned is

required to inflame it. The following table exhibits concisely the practical effects of different modes of preparing charcoal for gunpowder, the same kind of wood being used in each case, it shows (a) the analysis of the charcoals, and (b) the comparative initial velocities and pressures given by powders made in a precisely similar manner from these charcoals.

	No 1 Burnt 7 hours at a low heat	No 2 Burnt 6 hours at a medium heat	No 3 Burnt 4 hours at very high heat
Carbon, per cent.	78.23	81.23	87.55
Oxygen, and trace of nitrogen	10.06	13.10	8.20
Hydrogen	3.07	3.41	2.91
ASH	1.41	1.27	1.25
Initial velocity (feet per second)	151*	1 599	1393
Alt. in pressure in powder chamber (tons per square inch)	16.83	16.54	8.85

For the manufacture of gunpowder, only the crystalline Sulphur, electric negative variety of sulphur soluble in tri-sulphide of carbon (see CHEMISTRY, vol. v p 498) is used. Sublimed sulphur, commonly called "flowers of sulphur," which consists of minute granules of insoluble sulphur enclosing the soluble variety, is considered unfit for gunpowder, the reason assigned has usually been that, from the mode of manufacture, it is impregnated with sulphurous and sulphuric acids, but Professor Blaxam points out that in all probability it is the fact of the sublimed sulphur consisting of the electric-positive insoluble variety, which exerts an injurious influence upon the gunpowder made from it. Sulphur performs the part of a second "combustible" in gunpowder, but there is no doubt that its chief value as an ingredient thereof arises from its great inflammability, owing to its tendency to combine with oxygen at a moderate temperature; it inflames at about 560° Fahr, thus facilitating the ignition of the powder. Its oxidation by saltpetre appears also to produce a higher temperature than is obtained with charcoal, thus accelerating combustion, and increasing by expansion the volume of gas generated. An excess of sulphur would, however, be injurious by increasing the solid residue, in which the sulphur is found combined in various forms after the explosion. Some authorities have considered that, from its non-absorbent properties, sulphur renders gunpowders less hygroscopic, and more compact and durable.

Powders made from exactly the same materials, mixed in the same proportions, yet differ greatly in "explosive violence," which has been defined as the rate at which the powder burns or is converted into gas. This quality will depend chiefly upon the following properties:—(a) extent of incorporation, (b) the density of the powder, (c) its hardness, (d) size of the grains or pieces, (e) shape of the grains, (f) amount of glue. Although not altogether synonymous with strength, we may consider "explosive violence" as the quality upon which the value of gunpowder for any particular purpose chiefly depends.

Next to the selection of the precise description of charcoal to be used, no point in the manufacture of gunpowder requires such care and attention as the thorough intermixture of the ingredients,—the object being in fact to form out of the three components a new substance as nearly homogeneous as possible. It is usually considered that there is a limit of time beyond which no advantage is gained by continuing the "milling" or incorporating process, but it is certain that nothing that can be done to the powder afterwards will add to its strength, although we may modify its explosiveness, and that the very best powders, especially for small-arms, are milled the longest time. This question will be further treated under the head of manufacture.

Density
and
hardness

No physical property affects the explosiveness of gunpowder as much as its density. By density we mean the quantity of matter actually present in a certain bulk of the powder. Thus, if different quantities of meal powder, containing the same proportion of moisture, be compressed into equal bulks, say, for example, into cylinders of equal size, that which contains the most meal will be the densest. Hardness does not necessarily a relation to density, for a substance may be hard, and yet possess little density. Increase of density can only be given by compressing the meal into a smaller bulk, while increase of hardness can be arrived at by pressing the meal in a mortar containing

Other things being equal, increasing the density decreases the initial velocity, and, *vice versa*, a less dense powder gives a higher velocity, but also a greater strain to the metal of the gun. This is due to the less dense powder burning more rapidly than that with a dense close texture. If two grains, or pieces of powder, of equal size and similar shape but very unequal density, be burnt upon a glass plate, the less dense one will be entirely consumed before the denser one has finished burning.

Freedom from fouling is a very important property in small-arm powders. From the experience gained in selecting a powder for the Maxim-Henry rifle, it was found that, with the same description of charcoal, the slower the action of the charge the less fouling took place, thus modification of action was easily obtained by raising the density, and, however, a corresponding sacrifice of velocity in the bullet. The reason assigned was that the quicker-burning powder caused a rush of gas past the lubricating wad before the latter had time to act properly. A dense hard powder which will take a high polish or glaze will evidently keep better, and bear transport better, than a more porous and therefore more friable grain, which would easily form dust. It will thus be seen that many considerations enter into this question of density.

Size of
grains

The size of grain is one of the most important points to be considered as modifying the explosiveness of powder. Although a charge of powder appears to explode instantaneously, yet both ignition and combustion are comparatively gradual, the flame is communicated from one grain to another, and each burns in concentric layers until it is consumed, so that the combustion of the grains is not simultaneous. Meal-powder burns more slowly in air than when the powder is granulated, in consequence of the minuteness of the interstices, dust, especially in fine-grain powder, retards ignition by filling up the interstices. To go to the other extreme, as showing the advantage gained by granulating the press-cake, we may quote an experiment made some years ago. A small piece weighing 1.06 oz was placed in a mortar, and a light ball placed upon it, when it was fired, the ball was not thrown out. An equal quantity broken into 15 pieces, projected the ball 33 yards, broken into 50 pieces, the ball ranged 1077 yards, when the same weight of ordinary granular powder was used, the range was 5686 yards. It is most unsafe to attempt to apply to the action of gunpowder, when fired under enormous pressure, and especially when employed in large charges, the conclusions arrived at from its combustion in air. We may, however, assert that the weight of charge, the density, and all other conditions being equal, a charge made up of large grains or pieces of gunpowder will burn more slowly, and exert a lesser initial strain upon the gun than one composed of small grains, owing to the total surface of combustion being diminished by increasing the size of the pieces, this has been abundantly verified by the results of experiments with heavy rifled ordnance. On the other hand, the larger grains afford larger interstices between them for the passage of the flame, thus facilitating the ignition of large charges. Hence, a gunpowder may

possess a low rate of combustion and yet a high rate of ignition, and *vice versa*. For each gun, or charge of gunpowder, there is doubtless a size of grain which would produce a maximum velocity with a minimum initial strain, but as each kind of cannon powder has to be employed in more than one piece of ordnance, it is necessary to select that size which will best suit all of them.

The same quantity of powder meal made into two grains shape of equal density, but different shapes, will take different times to burn, the larger the surface exposed the quicker will be the combustion of the grain. A sphere being the smallest form in which a given quantity of matter can be placed, it follows that a certain amount of meal powder compressed into a spherical form will take longer to burn than the same quantity made into the shape of a flat scale, exposing a large surface. The rounded form of grain is the most favourable for the transmission of the flame, the interstices being larger and more regular than in the case of elongated or flat grains fitting into one another. Hence we may conclude that, to secure *uniformity*, it is better to have the constituent grains as nearly as possible of the same shape, and the nearer this shape approaches a sphere the better.

The drying process is one of considerable importance, *Glazing* both with reference to the explosiveness, and also the keeping qualities of the gunpowder. As regards the former point, it undoubtedly modifies the violence of the combustion, and thus it probably does by slightly retarding the ignition, a powder with a rough porous surface affording a better hold to the flame than one possessing a highly polished exterior. With the large "cubical" powder, used for heavy rifled ordnance, there is little or no appearance of what is commonly understood as *glaze*, or polish, from this process, but the corners and edges of the cubes are rubbed off, and the shape approximates more nearly to that of a sphere than in the case with the much lighter fine-grain powder, there seems to be also a certain hardening of the surface of the grains or pieces, partly the effects of friction, but probably due in part to the *sweating* the powder undergoes, a considerable amount of heat being generated in the glazing barrels. It is evident that, by taking away the sharp angles which would otherwise easily be converted into dust, and also by giving the grains a harder exterior, this process renders gunpowder the better able to bear transport, and to resist the deteriorating effect of a damp atmosphere. The addition of a thin coating of the purest graphite to cannon powders, although originally intended merely to modify the explosiveness, also renders the surface of the grains less absorbent. Military small-arm powders are never dressed with graphite, good fine-grain gunpowder will take a high finish without it, but, by its aid, a very inferior article can be polished up to a silvery brightness.

Moisture in gunpowder reduces the explosiveness by using Effect of up a portion of the heat generated by the combustion, to moisture get rid of the water, therefore the property of withstanding the absorption of moisture is a very important one for gunpowder to possess. All powder will take up from a normally dry atmosphere a certain amount of moisture, which will depend to some extent upon its density, but to a much greater degree upon the description of charcoal from which it is made. Slack-burnt or red charcoal is greatly more hygroscopic than black charcoal, or that burnt at a high temperature, and the absorbent properties of gunpowder made from the former are but little reduced by raising the density. Large cannon powder contains a greater percentage of water than the fine grain, and the actual amount present in any given sample will be affected by the prevailing state of the atmosphere, especially if kept in wooden barrels. To show the considerable effect upon the initial velocity of projectile, and present in bore of gun

caused by comparatively slight variations in the amount of moisture, the following results may be quoted from the experiments of Noble and Abel. The samples of "pibble" powder used were specially prepared for the Committee on explosives, differing only in the amount of moisture contained in them.

Percent age of moisture	Muzzle Velocity Feet per second	Maximum Pressure tons per sq. inch
0.7	1545	32.02
0.8	1537	31.95
0.9	1530	30.77
1.0	1523	30.18
1.1	1517	19.63
1.3	1512	19.12
1.4	1507	18.63
1.4	1502	18.18
1.5	1497	17.78

Keeping gunpowder in a very damp atmosphere will tend to separate the ingredients by dissolving a portion of the saltpetre, which crystallizes upon the surface of the grains or pieces.

FIRED GUNPOWDER

In the explosion of gunpowder, the products of combustion are very materially affected by the conditions under which it is fired,—whether burnt in the open air, exploded under very great pressure in a tightly closed vessel, or the products allowed to expand in the bore of a gun. It may, however, be stated generally that the oxygen of the saltpetre converts nearly all the carbon of the charcoal into carbonic acid (CO_2), a portion of which combines with the potash of the nitre to form carbonate of potash (K_2CO_3), the remainder existing in the state of gas. The sulphur is for the most part converted into sulphuric acid (SO_3), and forms sulphate of potash, a large proportion of which, probably by secondary reactions, becomes hypsulphite and sulphate. The nitrogen of the saltpetre is almost entirely evolved in the free state, and the carbon not having been wholly burnt into carbonic acid, there is always a proportion of carbonic oxide (CO) present.

The decomposition is so complicated, and varies so considerably under different conditions of experiment, that it is impossible to represent the transformation by any single equation, but the following expression may give some idea of the primary reaction—

There is a very large proportion of residue, which, on cooling, assumes the solid form. The experiments of Noble and Abel prove that it is *largely* very shortly after the explosion, indeed, it is probable that at the moment of maximum temperature, the ultimately solid products are more or less in a state of vapour, being deposited in a very finely divided state as the temperature falls.

When a charge of gunpowder is exploded in the chamber of a gun, a large quantity of gaseous matter is evolved in a highly condensed state,—its tension, or expansive power, is, moreover, greatly increased by the heat generated during the transformation. The pressure being equal in all directions, the work done upon the projectile is due to the expansion of the permanent gases in the bore of the gun, which force is also considerably sustained—on the reduction of temperature due to the expansion in great measure compensated for—by the heat stored up in the ultimately solid residue. Any calculation which does not take this latter point into consideration will give far too low an estimate of the actual force of fired gunpowder (see EXTERNALS).

With our present state of knowledge, it may be stated in round numbers that the gases evolved by gunpowder, if it *entirely fills the close vessel* in which it is exploded, will occupy at a temperature of 0°C and 760 mm barometric

pressure, about 280 times the volume of the original powder, and will give a pressure of about 6000 atmospheres, or 40 tons per square inch.

In view of the very different results which have been arrived at by various eminent authorities who have experimented upon fired gunpowder, the following brief account of their researches may be useful—

Robins, the father of scientific gunnery, in 1748 read before the Royal Society a paper describing experiments which showed that gunpowder, when fired, generated pressures which, in ordinary temperature and atmospheric pressure, occupied a volume 244 times greater than that of the unexploded powder. He further considered that the best evidence was to show that the tension of the permanent gases would be increased fourfold, and hence deduced the maximum pressure to be about 1000 atmospheres. In 1778 Dr Hutton Hutton communicated in the same manner an account of his celebrated researches on the combustion of powder; he deduced the maximum pressure to be about twice that given by Robins, or a little over 2000 atmospheres, deducing from the latter chiefly in the temperature, for he considered that the volume of gases evolved would occupy, under ordinary conditions, 260 times that of the powder. He also deduced formulae for giving the pressure of the gas and velocity of the projectile at any point of the bore, but no allowance is made for the loss of heat in proportion to the work done, this fundamental principle of thermodynamics being then unknown, the error thus occasioned is, however, not great, compensated for by the heat stored up in the non-gaseous products. In 1797 (Natal Rumford sent to the Royal Society his experimental determinations of the pressure given by fired gunpowder, which are remarkable, this being the first attempt to do this by direct observation. The closed vessel he used was, however, very small, being that to hold but 28 grains when filled, and he only succeeded in measuring the results up to a charge of 18 grains. His plan of operation was to ascertain by repeated trial the least weight which would just conduct the products of explosion, and thence to calculate the pressure, this he deduced from two series of experiments, which, however, gave some very anomalous results, to be as high as 100,000 atmospheres for the powder exploded in its own space. In 1823 Gay Lussac, the distinguished French chemist, estimated the volume of the permanent gases evolved at 450 times that of the powder itself, but General Fabert assigns very probable reasons why this result is so uncertain, he has determined to have been doubled in error. Gay Lussac found the percentage composition of the gaseous products to be 52.6 carbonic acid, 5 of carbonic oxide, and 42.4 nitrogen. In 1897 Hunsen and Schuch published (*Powder's Properties*, vol. i, p. 305) the results of their very important experiments, the chief conclusions were—(1) that the permanent gases represented only about 32 per cent of the weight of the charge, and as equal at the standard temperature and pressure about 160 times the volume of the original powder, (2) that the heat generated by exploding gunpowder in a close chamber is about 3400°C , and (3) that the tension of the permanent gases would be about 4371 atmospheres, or 29 tons per square inch.

His plan of operation was to ascertain by repeated trial the least weight which would just conduct the products of explosion, and thence to calculate the pressure, this he deduced from two series of experiments, which, however, gave some very anomalous results, to be as high as 100,000 atmospheres for the powder exploded in its own space. In 1823 Gay Lussac, the distinguished French chemist, estimated the volume of the permanent gases evolved at 450 times that of the powder itself, but General Fabert assigns very probable reasons why this result is so uncertain, he has determined to have been doubled in error. Gay Lussac found the percentage composition of the gaseous products to be 52.6 carbonic acid, 5 of carbonic oxide, and 42.4 nitrogen. In 1897 Hunsen and Schuch published (*Powder's Properties*, vol. i, p. 305) the results of their very important experiments, the chief conclusions were—(1) that the permanent gases represented only about 32 per cent of the weight of the charge, and as equal at the standard temperature and pressure about 160 times the volume of the original powder, (2) that the heat generated by exploding gunpowder in a close chamber is about 3400°C , and (3) that the tension of the permanent gases would be about 4371 atmospheres, or 29 tons per square inch.

(A) *When Fired in a Confined Space*—(1) The products of combustion are about 57 per cent by weight at ultimately solid state, and 43 per cent of permanent gases. (2) The tension of the gas at 760 mm barometric pressure about 280 times the volume of the original powder. (3) The tension of the products of combustion, when the powder entirely fills the space in which it is fired, is about 6000 atmospheres, or 40 tons per square inch. (4) The temperature of explosion is about 2500°C . (5) The chief gaseous products are carbonic acid, nitrogen, and carbonic oxide, with a little sulphuric acid and hydrogen. (6) The solid residue is mainly composed of potassium carbonate, sulphate, hypsulphate, and sulphide.

(D) *If then First in the Case of a Gun.*—(1) The products of combustion, at all events so far as regards the proportions of solid and gaseous matters, are the same as in the case of powder fired in a close vessel. (2) The work on the propellant is effected by the elastic force due to the permanent gases. (3) The reduction of temperature due to the expansion of the permanent gases is in a great measure compensated by the heat stored up in the liquid (fixed and solid) saline. (4) An expression is obtained showing the law connecting the tension of the products of combustion with the volume they occupy. (5) Equations are also deduced for the work that gunpowder is capable of performing in expanding in a vessel impervious to heat, and for the tension during expansion. Thence the measurements give a means of knowing the total work gunpowder is capable of performing in the bore of a gun, in terms of the density of the products of combustion, or the number of volumes of expansion. (6) The total chemical work of gunpowder when it is detonated expanded, for example, in a work of tubular length is about 488 foot tons per pound of powder.

They then discussed the fact that—(a) the fine grain powder is much decidedly smaller portions of gaseous products than large grain or cannon gunpowders, (b) the variations in the composition of the products of explosion, in a close vessel, furnished by one and the same powder under different conditions as regards pressure, and by two powders of same composition under the same conditions of pressure, are so considerable that no chemical expression can be given for the metamorphosis of a gunpowder of nominal composition, and (c) the proportions of the several constituents of the solid residue are quite as much affected by slight accidental conditions of explosion of one and the same powder in different experiments as by decided differences in the composition, as well as in the size of grain of different powders. It may, however, be remarked here that, while the pressure given by one of a gun is very seriously affected by the size of the grains or pieces of the powder, it was clearly demonstrated by these experiments that the *force exerted by solid gunpowders* is not affected by the apparent accidental variations in the nature of the secondary chemical changes resulting from the explosions, this fact renders the exact composition of the products of combustion of less practical importance.

The following table gives concisely the chief results arrived at—

Authors	Volumes of Gases Produced	Heat Evolved by Combustion	Turnover of the Gases	Pressure in Lbs
	Cent	Cent	Atmospheres	Psi sq in
Roberts	241		1000	816
Hansen	250		2000	276
Gay Lussac		18.2	2127	34
Bunsen and Schiel	251	1440	1174	29
Noble and Abel	245	2000	6000	12

As before stated, I select these cases for having these figures.

It is found that Roberts determined experimentally the amount of work lost by the heat communicated to the gun to be about 250 grammes until per grammes of powder in the case of a *closed vessel*. From the experiments of Noble and Abel this loss becomes reduced to a little at 25 per grammes of powder in the case of a *closed gun*. They have also calculated the energy in foot tons from the initial velocity obtained, and hence deduced the percentage of the possible theoretic work which is actually realized, for every rifled gun in the British service. This percentage, which they term the "factor of effect," is found to be greatest, viz., 93 per cent, in the case of the 38 lb gun, and least, 50.5 per cent, in the 7 pounder mountain gun, weighing 160 lb.

To determine the velocities, Noble and Abel employed two data measurement methods—(1) *directly*, by means of "cushion gages," invented at various points of the bore, this is an improvement on the Rodman piston gage, the pressure being obtained by the amount of compression given to a small cylinder of pure soft copper, (2) *indirectly*, by means of the chronoscope invented by Captain A. Noble, which measures the velocity of the projectile at given points in the bore, whence the precise velocity can be obtained (see GUNNERY). These processes, however, being obtained by the same method, according to the laws will vary greatly, other conditions being the same, according to the "explosiveness" of the powder, the chief object is to obtain a powder suited to the particular aim with which it is to be used.

Many foreign physicists are of opinion that the phenomenon of dissociation comes into play at the moment of maximum temperature, causing this carbonous acid gas (CO₂) to be decomposed into carbonic oxide (CO) and oxygen. However, Noble and Abel show that, if such be supposed to occur, the loss of heat absorbed in the decomposition would more than compensate for the increase of volume.

PREPARATION AND PURIFICATION OF THE INGREDIENTS

The three ingredients of gunpowder may be purchased in the market in a prepared or refined state, and this is done to a greater or less extent by many powder makers. However, the royal gunpowder factory, as well as some of the great private firms, prepare and purify the three ingredients from the commonest materials with the double object of insuring uniformity in the qualities of the

powders made, and of avoiding, so far as practicable, the introduction of the least particle of grit or other foreign matter, which might cause serious accidents.

The chemical of the refining process is based upon the fact that Refining sulphate of soda is soluble in hot water, whereas the salt which is insoluble in either. Water at 212° Fahr. holds about seven times as much nitre of potash in solution as water at 70° Fahr.; if, therefore, a saturated solution of sulphate of soda is mixed with an equal volume of 212° Fahr. and the chloride of sodium and potassium are contained in the liquor, the solution cools to 70° Fahr., six-sevenths of the nitre will be deposited in the form of crystals, which can easily be removed, whereas the foreign salts will still remain in solution.

The following is a brief account of the improved mode of refining sulphate, introduced some years back at Walbham Abbey, and now adopted at the chief gun works in England. The sulphate crystals are capable of holding about 100 grains each, and are stirred with false iron bottoms, which are perforated with holes to allow sand and other mechanical impurities to fall through. Being chafed with 250 gallons of water, nearly the whole of the sulphate is dissolved, and the solution begins to boil, the dark scum formed on the surface is carefully skimmed off, and cold water from time to time thrown in to induce it to rise, the boiling being continued until there is no more scum, the copper is then filled up with cold water, and the solution again made to boil for a few minutes, after which the liquor is allowed to go down. In about two hours more the solution will have fallen to the proper temperature, 220° Fahr. (57° C 53), for pumping out, it is then filtered through downy bags suspended on a frame, and collected by troughs at the bottom of the apparatus, which is at about 180° Fahr. These latter are large shallow pans of copper, in which the liquor is kept agitated either by long uninduced wooden looms, or by machinery, it is cooled, the crystals fall to the bottom, and are from time to time thrown into tubs, which are shaken by means of perforated copper shovels. When the temperature falls below 70° Fahr. the agitation is ceased, and any crystals which may afterwards form are removed by means of a ladle. After being thus allowed to get rid of some of the liquor, the crystallized sulphate, having almost the appearance of snow, and technically called "flour," is taken into the "washing casks," it is there subjected to three successive washings with water, distilled being preferable, which is allowed to drain off through a plug hole at the bottom of the casks. Three "washings" are generally conducted to an underground tank, and kept either there using in the refining process, or boiled down in "evaporating pans" holding about 300 gallons, until the liquor is sufficiently concentrated for the sulphate to crystallize, when it is run into small copper pans, and set aside to cool, this course is also usual with the molten liquor from the large cooling casks, and the resulting crystals are dried as rough nitre, for these large crystals always contain liquor containing impurities. After drying for a night the refined sulphate is removed to store tanks, and is then used without any further purification.

It is found that the "washing casks" are so arranged as to maintain a temperature in it from 3 to 5 per cent, in them carefully ascertained, and allowed for in the mixing house. Neither the solid residue from the pots and copper nor the molten liquor from the evaporating pans is thrown away, but is used in the preparation of the evaporation, every available portion of sulphate is extracted, and the residue sold, it chiefly consists of chlorides of sodium and potassium, with some sulphate. The jets traps in which the sulphate is deposited are also bound down.

The large percentages of sulphate contained in damaged powder makes it worth while to extract the nitre by boiling in large copper pans, filtering and crystallizing in small pans, or under edge runners from the powder houses, in various stages of manufacture, are "salted" in the same manner.

Refined sulphate for making gunpowder is tested as follows—(1) with lime and red litmus paper, for acids or alkalis; (2) for the presence of chlorides, with solution of nitrate of silver; (3) for sulphates, with chloride of barium, forming the insoluble sulphate of barium.

By the old method of refining the solution was left to crystallize in coolies, and the drained crystals fused or melted in iron pots at a heat of about 600° Fahr., the molten sulphate was then poured into moulds, broken up when cold, and then thrown away.

The wood for charcoal is cut in spring, so that the bark may Charcoal strip off easily, and is stacked for about three years to season it, burning but a considerably shorter time will suffice. Being cut in lengths of 3 feet, the wood is packed in iron cylinders, or under edge runners, "ships," which are then inserted in the "cylinders" or retorts, the latter being built into the wall in sets of three with a furnace underneath, arranged so as to allow of the complete regulation of the heat, the flues are surrounded the retorts, and the space between them is left in the rest and at the end of the ship, corresponding with a similar

Detas
mination

bore

Therom
tion im
probable

opening in the robot, through which, by means of pipes, the inflammable gases resulting from the burning of the wood are conducted into the furnace, and thence burnt, thus saving a considerable amount of fuel. There are also pipes which receive and carry off the tar and pyrolysates, and polished. In the powder works of Messrs Hall & Son of Faversham, the robots are disposed three on each side of the furnace, and the connecting pipes and dampers are so arranged that the gases from either set, or from any single cylinder, can be utilized. For the clearing of the wood from any of the others, by this means it is claimed that a little fuel is required beyond the quantity needed to warm the furnace and partially heat the first set of robots.

That the wood is suitably selected is shown by the blue colour of the gunpowder, which indicates the formation of carbonous oxide, the door of the robot is then opened, and the ship is withdrawn by means of a truck, and placed in a large iron cask having a close fitting lid, where it is left for 24 hours, till cool enough to be turned out and put into store. The charcoal is carefully picked over by hand, to ensure its being of uniform quality, and is kept from ten days to a fortnight before being ground, to obviate the danger of spontaneous combustion, to which it is liable if ground too soon after burning, the gases from the heat generated by the very rapid absorption and condensation of oxygen from the air by the finely powdered charcoal.

Properly mixed charcoal for gunpowder should be jet black in colour, and its texture should show a sharp siliceous surface, it should be light and spongy when chopped on a hard substance, and so soft as not to scratch polished copper. Black burnt charcoal, or that picked at a very low temperature, is not so known by its reddish brown colour, especially a hot ground, and this peculiarity can be recognized in the powder made from it, which is reduced to a fine state of division. Charcoal burnt at a very high temperature is known by its hardness, metallic ring, and greater density.

In France, charcoal is prepared by subjecting sapwood stems into the robots for a certain period.

The charcoal mill in shape resembles an calve of coffee mill, a cone with a shaft or spindle, both being secured with diagonal teeth and the shaft is apart at top, but gradually approaching one another below. The pulverized charcoal is thence conducted by a simple mechanical arrangement direct into a cylindrical frame or "sieve," about 8 feet by 4 feet, set at a slope and covered with copper wire cloth of about 32 meshes to the inch, all that is fine enough to pass through the lid covering falls into a bin which encases the mill, and the coarser particles pass on to a tub at the further end, in order that they may be ground over again. The ground charcoal stores should always stand by itself, in case of spontaneous combustion taking place.

The sulphur from Sully known as "Lacra Sixte" is employed for the best gunpowders, it undergoes a rough purification before impurities, leaving from 8 to 4 per cent. of earthy impurities. Formerly these were removed by simply melting the "rough" sulphur in an iron pot, and then holding it into large wooden moulds or tubs, saturated with water to keep the sulphur out of the cracks, when cool enough, these tubs were unhooked, and the top and bottom of each mould of sulphur cut off. In the recent days, however, the sulphur is cleaned by distillation in a simple apparatus. A large iron "melting pot," or robot, is set in brick work, about 4 feet above the floor, with a furnace underneath, this robot has a heavy movable lid, which is luted into the pot with clay, and in the lid is the air escaping, closed by iron or lead plug. From the melting pot lead two pipes at right angles to one another, one to a large cucurbit "dome," or subliming chamber, and a smaller pipe to an iron "receiving pot" placed on a lower level than the robot, the latter pipe has an iron valve, "jack," which, through which cold water is allowed to circulate. The communication of these pipes with the robot can be shut off or opened as occasion may require by the use of valves worked from without.

A charge of about 25 cwt. of rough sulphur in small pieces being placed in the robot and the furnace lighted, the pipe leading to the dome is left open, as well as the plug hole in the lid, but that leading to the receiving pot is closed, after about two hours, a pale yellow vapour rises, when the plug in the lid is put in, and the vapour allowed to pass into the dome, where it "sublimes" or condenses on the sides and floor in the form of a fine powder, known as "flowers of sulphur." In about three hours from the commencement, the vapour becomes of a deep sooty colour, when the pipe leading into the dome is closed, and that into the receiving pot opened, at the same time cold water from a tank overhead being allowed to circulate through the jacket, the vapour is then condensed in the pipe, and runs into the receiving pot below in the form of a clear orange coloured fluid. When the jacket commences to get cold, the receiving pipe is closed, and the communication with the dome is interrupted, so that the rest of the vapour may pass into it, the furnace door being at the same time thrown back, the impurities remain at the bottom of the melting pot, and are thrown away. The flowers of sulphur thus obtained, being unfit for the manufacture of gunpowder, are placed in the melting pot as rough sulphur. A leaden pipe passes from the lid of the receiving pot

into a small wooden chamber lined with lead, in which any vapour still remaining uncondensed may be deposited, as in the dome. The distilled sulphur is allowed to cool down to about 220° Fahr, when it is ladled into wooden moulds, is above described, and set aside to cool. The tests for refined sulphur are the following—(1) has a small quantity on polished iron, the amount of residual should not exceed 0.25 per cent., (2) boil a little with water, and test with blue litmus paper, which it should only very feebly reddens.

The sulphur from the moulds, being broken into pieces, is ground Pulver under a pair of non edge mallets, similar to those of the incipient stage of gun mills, but of less size, after this it is passed through a steel sulphur mill in which it is used for adding the second, and covered with steam from copper wire cloth, having 44 meshes to the inch.

MANUFACTURE OF GUNPOWDER

The following list will give a general idea of the chief processes of manufacture, properly so called, though which of many gunpowder passes, although it will be understood that more or less variation takes place in some of the very different descriptions of powder now made—(1) mixing the ingredients, (2) incipient, or "milling," (3) breaking down the mill-charge, (4) pressing, (5) granulating, or cutting the press cake, (6) dusting, (7) glazing, (8) second dusting, (9) storing, or drying, (10) binning.

The following is the most approved method of mixing. The ingredients are carefully weighed out in the proper ingredients for a 50 lb mill-charge, with an overt amount of saltpetre according to the moisture found to be contained in it, they are then placed in the mixing machine, which consists of a cylindrical gun-metal or copper drum, with an axle passing through its centre, upon which are disposed several rows of gun-metal fork shaped arms, called "flyers," the machinery being so arranged that the flyers and drum revolve in opposite directions, and at different rates of speed. After being mixed in this machine for about five minutes, the composition is passed through a hand sieve over a hopper, falls into a bag placed below, and is then up ready for the incipienting mill, it is now called a "green" charge.

Fig 1

Fig 2

Figs 1 and 2—A, sectional view of incipienting mill, showing arms and plungers (p, p), C, umb of belt, M, machinery in tank, underground, D, discharging apparatus, E, lever board, or shuttles, 4, tank, f, f, f, floor line.

The incipienting mill (see figs 2 and 3) consists of a lower circular iron or stone bed, (about 7 feet in diameter, firmly positioned

fixed in the floor of the building, whereon a pair of iron or stone cylindrical edge-runners revolve; formerly, both were made of a dark grey limestone which took a high polish, but the newer mills have cast-iron beds and runners, the edges of the latter being now usually surface-chilled. The average diameter of the runners is 6 feet, and their width about 15 inches; they have a common axle, which rests in gun-metal bouches in a solid cross-head attached to a vertical shaft; this shaft passes through a bearing in the centre of the bed, and is in gear with the driving machinery, which is placed above the runners in the old water mills, and beneath the bed in cast-iron tanks in the new steam mills. Each runner weighs about 4 tons, and the speed averages 8 revolutions per minute. The bed has a sloping rim on the outside, called the "curb," and on the inside an edge formed by the "cheese," or bearing, through which the vertical shaft passes. The runners are not equidistant from the centre of the bed, one working the part of the charge near the centre, and the other the outer portion, but their paths overlap. Two "ploughs" of wood, shod with leather, are attached to the cross-head by arms and brackets; one working next the vertical shaft, and the other close to the curb, the ploughs throw the composition under the runners as it works away from the latter.

FIG. 3.—Plan of runners and bed.

The charge, when spread evenly on the bed by means of a wooden rake, contains about 2 parts of water (the moisture of the saltpetre) and a further quantity of from 2 to 6 parts is added from time to time, according to the state of the atmosphere, for the threefold purpose of preventing powder dust from flying about, facilitating the incorporation, and reducing the effect of an explosion; if too wet, the runners would lick up the composition from the bed. During the time of working, the millman enters the mill occasionally, takes a wooden "shovel," and pushes the outside of the charge into the middle of the path of the runners, so that every portion may be equally incorporated.

The action of the runners is a combination of rolling and twisting, and has, on a large scale, somewhat the effect of a pestle and mortar, crushing, rubbing, and mixing the ingredients, so as to effect an intimate union. The time of milling depends upon the nature of the powder. For good fine-grain powders it varies from four to eight hours, but the very best sporting gunpowder is said to be as long as twelve hours under the runners; blasting and cannon powders are incorporated from two to four hours, the period being rather longer where the lighter stone runners are used. It is of the greatest importance that the mills should be carefully attended to by experienced men, as the whole goodness and uniformity of the powder depends upon this process, and no after treatment can remedy defective incorporation.

When the composition, which has now become "mill-cake," is ready for removal from the bed, it should be homogeneous in appearance, without any visible specks of sulphur or saltpetre, and of a dark greyish or brownish colour, according to the charcoal used. The mill-cake is carefully tested to ascertain whether it contains the proper amount of moisture; this should be from 2 to 3 per cent. for

fine-grain powders, and 3 to 5 per cent. for the larger descriptions. Sometimes a small portion is roughly granulated, and "flashed" on plates of glass or porcelain; a good powder should flash off, leaving nothing but some smoke marks, but, if badly incorporated, the plate will be coated with specks or beads of solid residue.

In former days the ingredients were incorporated in "stamp-mills," which were simply large mortars and pestles, the latter merely raised up by some cam arrangement and allowed to drop by their own weight, the charge being about 12 lb, and the weight of the stamp 50 lb or thereabout. The stamp or *piilon* mills are still used in France and Germany, as well as the *moûlins-à-torcheaux*, in which the composition is put, with about an equal weight of brass or lignum vite balls, into large barrels, which are made to revolve for a certain time on their axes; this method of incorporation is sometimes employed in conjunction with edge runners.

There is more danger of an explosion during the milling than in any other process of manufacture; but, owing to the limitation by law of the weight of charge permitted to be under the runners at one time to 50 lb, as well as to the great precautions taken, there is seldom any fatal result. The millmen only enter the mill occasionally to "liquor" the charge or give it a shove over, and at Waltham Abbey they wear incombustible clothing with a cap fitting over the ears, and gunklets of the same material. The roof, front and rear sides of the mills are usually constructed of very light boards, or even of canvas on a wood frame, while the partitions between each pair of runners are of solid masonry. The force of the explosion of a mill charge materially depends upon the length of time the incorporation has been in progress.

Directly over the bed of each mill is a flat lever-board or "shutter" (see fig. 1) in gear with a tank of water, so arranged that, when the shutter is raised on its pivot by an explosion, the water is upset into the bed; a horizontal shaft connects all the shutters in a group of mills, so that the explosion of one mill at once drowns all the remaining charges. The set of tanks can also be pulled over by hand.

The process of breaking down, although a subsidiary one, Break- is strictly necessary in order to reduce the mill-cake to a fine ing meal, so that it may be conveniently loaded into the press box, and receive as uniform a pressure as possible. The breaking-down machine (see fig. 4) consists mainly of two pairs of gun-metal rollers, set in a strong frame of down.

FIG. 4.—Breaking-down machine. H, hopper; B, endless band; R, rollers; M, boxes to receive meal.

the same material; one roller of each pair works in sliding bearings connected with a weighted lever, so that any hard substance may pass through without dangerous friction. An endless canvas band, having strips of leather sewn across it, conveys the pieces of mill-cake from a hopper, capable of holding 500 lb to the top of the machine,

where it falls between the first pair of rollers, after passing through the second pair, which are directly below, the meal is received in wooden boxes, piled upon a carriage, and is ready for the press.

Pressing

The press-box is usually of oak, with a strong gun-metal frame, and is constructed that three of the sides can turn back on hinges, or be screwed firmly together. Being laid sideways, the top temporarily closed by a board, and the uppermost side alone open, a number of copper plates

are placed vertically in the box, and kept apart (at a distance depending upon the description of gunpowder required) by two racks, which are afterwards removed, the box is then loaded with some 800 lb of meal, which is rammed evenly down between the plates with wooden laths, and the racks withdrawn, so that the plates are only separated by the meal between them. The present upper side of the box being firmly screwed down, the box is turned over, and placed on the table of the hydraulic ram, under the fixed press-block, the plates being now horizontal (see fig. 5). The pumps which work the press (in a separate house) are then set in motion, and the press block allowed to enter the box a certain distance, when the edge of the latter releases a spring catch and rings a bell as a signal to stop the pumps, the powder is kept under pressure a few minutes, after which the ram is lowered, and the box removed and unloaded. For all granulated powders the press cake is broken up into pieces and put into tubs, but for the cubical cannon powders the slabs are pressed to the exact thickness required, and are carefully kept whole.

The above mode of regulating the pressure is found to give more reliable results than trusting to the indicator gauge of the hydraulic press, for the reason that the elasticity, or resistance to pressure, of the meal varies with the amount of moisture present in it, and the state of the atmosphere. To get uniform density, equal quantities of meal, containing equal amounts of moisture, must be pressed at the same rate into the same space. In practice, however, the moisture in the meal will slightly vary, whatever care be taken with the mill rake, owing to the hygrometric state of the air causing a difference by the time it comes to the press. It is therefore necessary to alter the exact distance the press block is allowed to enter the box, not only with the nature of the powder, but with the season of the year, and even according to the prevailing state of the weather.

On the Continent, the operation of pressing is sometimes altogether omitted, and the requisite density given merely by the weight of the runners revolving very slowly, the charges being worked with a considerable amount of moisture in them, and the less dense edges of the cake rejected, by this plan it is, however, almost impossible to ensure uniformity in the powder produced. The meal is also sometimes pressed by passing it, on an endless band, between large rollers revolving at a slow speed, the less dense edges of the cake being cut off by fixed knives

FIG. 5.—FIG. A, press box, B, press block, C, hydraulic ram.

For some centuries, gunpowder remained in the form of *Grana* dust or "meal," being, in fact, simply the ingredients being ground up together. Granulating or "cutting" the powder was a great step in advance, but it is doubtful whether this operation was intended to increase its strength, or merely to render it more convenient for charging small arms, for which alone coined powder was used for many years, whilst meal powder was still employed for heavy guns, the latter was called "serpentine" powder in the time of Edward VI, probably in allusion to the name of one of the pieces of ordnance then in use. However, during the reign of Elizabeth, the experience of the great additional strength imparted by the coning process, for the reasons already explained, led to the universal introduction of coined powder, except for punning,—both in cannon and small arms,—for which purpose meal powder remained in use as late as the reign of Charles I.

The old method of granulating was to place the press cake in sieves, provided with two bottoms of thick parchment prepared from bullock's hides, and perforated with holes, those in the lower bottom being much the smaller, a large number of these sieves were attached to a wooden frame, hung by ropes from the ceiling, which received a violent shaking motion by means of a crank underneath. Into each sieve was put a disk of lignum vitae, to break up the cake, and force it through the larger apertures; the grain produced was retained between the bottoms of the sieves, the dust passing through the fine holes in the lower ones, and falling on the floor of the house. The grain was afterwards separated into sizes by being passed through wire sieves. These machines were clumsy and dangerous, and the accidents which happened with them have caused them to be generally supplanted by better apparatus, although some of the old frames are still in use.

The granulating machines used in the royal factories in England and in India, as well as in the best private works, are constructed upon a principle introduced by Sir William Congreve, but since improved upon. Three or four pairs of conical rollers with pyramidal shaped teeth, are fixed obliquely one above the other in a strong framework (see fig. 6), the sizes of the teeth vary according to the kind of grain required, but decrease from the top pair, and for fine grain powders, the lowest pair would be smooth, one roller of each pair works in a sliding bearing, having a counterweight attached to prevent undue friction. Each pair of rollers is connected with that next below, by a short rectangular section of copper wire, while, underneath all the rollers, as they are placed, at the same slope, two or more long wire-screens fixed in a frame having a wooden bottom, both the frame and the short connecting screens are hung to the machine by strips of linc wood, and, when at work, a quick vibratory motion is given to all the screens by means of a polygonal wheel upon the main frame working against a loose smooth wheel attached to the screen frame. A large hopper, which rises by the action of the machine, feeds the press cake upon an endless canvas band, as in the breaking-down machine, and carries it to the top pair of rollers, whence it falls upon the first shot screen, all that is fine enough to pass through is sifted out by the shaking action of the long screens below, and travels down upon whichever screen has meshes fine enough to retain it, the pieces too large to pass through the shot top screen are carried to the next pair of rollers, and so on. At the lower end of the long screens are placed boxes to receive the different sizes of grain, the "chucks," or pieces too large for any grain, are again passed through the machine, while the dust which falls upon the wooden bottom, and is received in the undermost box, goes to the mill to be worked up for forty minutes as a dust charge. Formerly at Waltham Abbey both musket (F G) and cannon powder (L G) were granu-

lated in the same machine at the same time, but dogwood charcoal being now used for small-arm powders, one description only is usually made, so that but two long screens are required to define the higher and lower limits as to size of grain; for example, all that will pass through a 12-mesh and be retained upon a 20-mesh screen would be "rifle-fine-grain" (R.F.G.) powder, suited as to size for the Snider and Martini rifles. Modifications of this machine are used by private makers, the grain being usually separated into various sizes by hand-sieves.

Pebble or cubical powders for heavy ordnance are granulated, or "cut," in special machines which divide the pressed cake first into strips, and then again cross-ways, into cubes of $\frac{3}{8}$ inch and $1\frac{1}{2}$ inch length of edge respectively. This is effected by two pairs of gun-metal or phosphor-bronze rollers, which have straight cutting edges arranged at suitable intervals along their surfaces, the slabs of press-cake being fed vertically between the first pair of rollers. The resulting strips are carried along upon a board, by means of a skeleton band, which receives each strip of cake

FIG. 6.—Granulating machine. A, hopper, with raising arrangement; B, endless band; C, C, C, C, four pairs of rollers; D, D, D, short screens; E, E, long screens; F, box for dust; G, box for grain; H, box for chucks; K, bottom board.

between two laths of wood; they then drop from the board upon an endless canvas band a little below, travelling in a direction at right angles to their previous motion, and are conveyed *endways* to the second pair of rollers. To prevent the strips of cake from fouling one another, the board upon which they first fall has a reciprocating motion given to it by means of an endless chain, one link of which is studded

FIG. 7.—Rollers of cube-cutting machine.

to a bracket underneath the board; consequently, as the board travels backwards, the strips are deposited at intervals, *in echelon*, upon the canvas band. The diagram (fig. 7) shows a portion of the machine. The cubes, &c., fall into a small reel fixed at a slope beneath the machine, which allows the dust and fragments to pass between its wires while the properly sized pebbles or cubes are delivered into boxes. The large $1\frac{1}{2}$ -inch powder has, however, afterwards to be picked over by hand.

Dusting. All grain from the granulating machine is called "foul-grain," and has to be deprived of its dust in reels, consisting of a cylindrical frame-work about 8 feet long by some 2 feet in diameter, covered with a dusting cloth or canvas of from 18 to 56 meshes to the linear inch, according to the size of grain. These reels are either "horizontal" or "slope," according to the position in which they are fixed and the object in

view. Slope-reels are open at both ends, fixed at an angle of about 4° , and are used for fine-grain powders as they come from the machine, when they contain more dust than the larger grain, especially if made from dogwood charcoal; the powder is poured in at the higher end, and received in barrels at the other end. The larger grained powders are dusted for about half an hour in a horizontal reel, with closed ends, the charge being from 250 to 300 lb; one end of the reel is made to lower for the purpose of unloading. Both kinds of reel are enclosed in cases to receive the dust, which, as before, is sent back to the incorporating mills for 40 minutes or so.

The theory of glazing gunpowder has already been discussed. All descriptions are glazed, for varying periods, in glazing barrels or "churns" (fig. 8), which are usually about

FIG. 8.—Glazing barrels. A, elevation, showing door of case; C, hoppers for loading; B, section through barrel (showing opening in dotted lines).

5 feet long by 2 to 3 feet in diameter, and revolve some 34 times in a minute; however, barrels of much greater diameter and less length are occasionally employed, revolving at a slower rate. The charge for each barrel is ordinarily 400 lb, and the fine-grain powders are mixed with a pro-

portion of the "chucks" or larger pieces, which are afterwards sifted out. The glazing process causes a great alteration in the appearance of the grain, especially in that made from dogwood; the dull brownish hue is replaced after a few hours by a fine black colour with more or less polish. Some powders are glazed from 10 to 12 hours, a considerable amount of heat being generated by the friction. Fine-grain powders are again passed through the slope reel after glazing.

Sieving. All kinds of gunpowder are dried in the same manner. The "stove," or drying room, is fitted with open framework shelves or racks, the heat being produced by steam pipes underneath. The powder is spread upon either copper trays or wooden frames with canvas bottoms, each capable of holding about 12 lb, which are then placed upon the racks. Not more than 50 cwt. may be dried at one time. The length of time required for stoving depends upon the nature of the powder, and the proportion of moisture it contains; it varies from about twelve hours for fine-grain up to three or four days for the very large cannon powders; the heat ranges from 120° to 145° Fahr., the temperature being gradually raised or lowered. It is most important that a stove should be well ventilated, so that a constant current of hot dry air may be supplied, and the air charged with vapour carried off; if this be not done effectively, the moisture would be recondensed upon the powder as the temperature was lowered.

Finishing. The drying process produces a small portion of dust which it is necessary to remove; but the finishing process has, especially upon the fine-grain powder, a much more considerable effect than the mere removal of dust. It is usually effected by being run from two to three hours in a horizontal reel (see fig. 9), the charge being 300 lb, and acquires a very glossy appearance, if the quality be good, even without the addition of graphite, which is very commonly added to sporting gunpowder. Large cannon powder, such as "pebble" and "cubical," is finished in large skeleton wooden reels, shaped like barrels, and enclosed in cases; after being run for about three quarters of an hour,

FIG. 9.—Horizontal Dusting Reel (longitudinal section). A, cylindrical reel; B, reel case; C, apparatus for lowering one end for unloading; D, hopper for loading; E, opening in reel for loading; F, barrel for unloading into.

a small portion of the purest graphite (2 oz. to 400 lb of powder) is introduced in muslin bags, and the powder is run for a short time longer. This skeleton reel will hold a whole "glazing," as the contents of four glazing barrels is termed, being about 16 barrels of 100 lb each, and advantage is taken of this finishing process to mix together a number of glazings, so as to get a batch of 50 or 100 barrels giving uniform results at proof. These batches are afterwards "blended" together in four-way hoppers, with others of opposite character, should they not in all respects be up to specification, and any quantity of gunpowder so finished or blended as to give identical results at proof is termed a *brand*, and receives a distinctive number.

Upon the introduction of very heavy ordnance, firing large charges, it was found that the ordinary (L.G. or R.L.G.) cannon powder was too sudden in its action, owing to the whole charge being consumed before the projectile had sensibly moved from its seat in the bore, thus causing a most violent strain to the metal of the gun. To obviate this defect, the grains or pieces were made much larger, so as to diminish the total surface of combustion, and, consequently, the volume of gas evolved at the first instant of explosion; the powder was also given a considerably higher density, which retarded its combustion. These changes resulted in the adoption of the pebble and cubical powders, already mentioned, in England, and in America, of "Mammoth" powder, consisting of large, irregular-shaped American grains (k, fig. 10) from 0"6 to 0"9 in size; an improvement mammas since been made in this powder by pressing it in uniform-sized pieces, of the shape shown in i, fig. 10, being the frusta of two hexagonal pyramids, separated by a prismatic space left rough.

FIG. 10.

The figures a to k show the relative sizes and shapes of grain now commonly employed for military purposes in Europe and America, except that the three largest powders—pebble (a), prismatic (f, g), and cubical (h)—are figured half the real size to save space, whereas the remainder indicate the actual dimensions of the grains. Powder for small-arms is represented in e; all the other descriptions are intended for cannon of various sizes.

The improvements above described materially lessen the Rodman's initial strain, at the expense of requiring a longer gun to perform the powder completely, but it still remains true that, even with a charge composed of large, dense pieces, the evolution of gas is greatest at the commencement of combustion, and decreases as the grains burn away, although

the space occupied by the gases, increases as the shot travels along the bore. This is exactly the opposite of what should theoretically take place, and causes the maximum pressure to be excited before the inertia of the projectile has been overcome. So far back as 1860, these considerations led General Rodman, the eminent American artilleryist, to employ, in the experiments with his 15-inch and 20-inch cast-iron guns, what he termed a "perforated cake cartridge," composed of discs of compressed powder from 1 to 2 inches thick, and of a diameter to fit the bore, pierced with holes running parallel to the axis of the gun. In his *Properties of Metals for Cannon, and Qualities of Cannon Powder* (Boston, 1861), Rodman demonstrated mathematically that such an arrangement of the charge would relieve the initial strain by exposing a minimum surface at the beginning of the combustion, while a greater volume of gas would be evolved from the increasing surfaces of the cylindrical hollows as the space behind the projectile became larger, this would tend to distribute the pressure more uniformly along the bore. The results of experiment perfectly bore out his theory, but he found it more convenient for several reasons to build up the charge in layers of hexagonal "prisms" of comparatively small size, fitting one another, instead of having the cakes or discs as large as the bore.

Prismatic powder

The civil war in America most probably interfered with the further development of General Rodman's powder, but the idea was taken up by a Russian military mission in the United States, and resulted in the manufacture on a large scale by Russia of what is now known as "prismatic powder." It has since been adopted in Germany for use in all heavy rifled ordnance, for the very largest guns, such as Kripp's 70 ton gun, this powder has been recently made with one central hole, having a higher density (1.78) than the original seven-hole prisms, which were about 1.68, the external dimensions are the same, 1 inch high by 1.36 in diameter. The prisms are so arranged in the cartridge that the hollows are continuous throughout.

Mode of manufacture

Prismatic powder represents a distinct class, the peculiarity of which is that each grain or piece is pressed separately in a metal mould. In the British service, powder for heavy rifled guns, in the shape of small cylindrical pellets, with a hollow half-way through, was made some twelve years since, but has been superseded by the pebble or cubical powder cut up from press-cake. To make this class of gunpowder, whether prismatic or cylindrical, we need—(1) a mould in which to place the meal or granulated powder, usually a number of moulds are contained in one plate, (2) a punch to fit each mould accurately with which to compress the powder, and needles to form the perforations, (3) an appliance for pressing the finished pellets or prisms out of the moulds, or this may be done by the punches themselves, if the moulds are closed by a removable upper plate.

The requisite pressure may be given either by hydraulic machinery, as at Waltham Abbey, or by means of a cam or eccentric on a shaft driven by steam or water power, as in the Russian and German prismatic machines. By the former plan a large number of pieces may be pressed slowly at one operation, but by the latter only about six prisms can be formed at a time, the machine, however, works very quickly, and has a small hopper for the meal or grain, and a self-feeding apparatus, the mould plate sliding backwards and forwards, so as to be alternately underneath the hopper and punches. Self-feeding machines of this nature are found to get clogged when used with powder-meal, and this was doubtless the chief reason why granulated powder was first used, the size of grain is about that shown in fig. 10, b. It is probable that a more uniform density could be given to the prisms by hydraulic

pressure than by the cam arrangement, the latter is said to exert a maximum pressure of 2000 lb. on the square inch. The prismatic powder only needs careful drying at a moderate heat to finish it.

It has been found that all powders thus made possess less explosiveness than those granulated or cut up from press-cake, the smooth surfaces of the pieces apparently afford little hold for the flame, and thus they ignite slowly, by some this is considered a defect, but by others an advantage. For this reason, as well as those already detailed, prismatic powder stains the metal of the gun less, in proportion to the velocity obtained, than pebble or cubical, but, to give the projectile an equal velocity, the charge of prismatic must be considerably larger. The cost would probably be also greater, weight for weight.

PROOF OF GUNPOWDER

The tests to which powder is subjected are as follows—

1 *For proper Colour, amount of Glaze, sufficiently hard and crisp Texture, and Freedom from Dust*.—These points can be judged by the hand and eye alone, and require a certain amount of experience in the examiner. The cleanness of the powder is tested by pouring a quantity from a bowl held 2 or 3 feet above the barrel, if there be any dust it will be thus easily detected. If it is injured by damp there will be little or no dust, but the grain will be "rotten," and may be broken between the fingers, minute crystals of salt petre may be also detected on the surface in a good light.

2 *For proper Incorporation*.—By "flashing," that is, burning a small quantity on a glass, porcelain, or copper plate. The powder is put in a small copper cylinder, which is then inverted on the flashing plate, this provides for the particles being arranged in nearly the same way each test, which is very important. If the powder be very large, it must be broken up and sifted to a certain size through a small hand-sieve. Properly made gunpowder should "flash," or puff off, when touched by a hot iron, with few "lights" or sparks, leaving only some smoke marks on the plate. A badly incorporated powder will give out a quantity of sparks, and leave specks of uncombined salt-petre and sulphur, forming a dirty residue. Powder made from very slack burnt charcoal, or which has been injured by damp, will always flash badly.

3 *For Shape, Size, and Proportion of the Grains*.—Shape can be judged by the eye only, and the size of the grains can be measured, or the number of pieces to 1 lb. counted, granulated powder may readily be sifted upon the two sieves which determine its higher and lower limits of size. The proportion of different sized grains is ascertained by using three or more sieves. For example, the Government small-arm powder is sifted with 12-mesh, 16-mesh, and 20-mesh sieves, all must pass the first, not less than three quarters be retained upon the second, and only one sixteenth part is allowed to pass the last-named sieve.

4 *Density*.—Formerly this was ascertained by "cubing," or finding the exact weight of a carefully constructed box of known contents, when filled with powder in a particular manner. But as this plan gave only an approximate result, a mercurial densimeter has been substituted, by means of which the density can be ascertained to three places of decimals. Briefly, the machine determines with great accuracy the weight of a globe when it is (a) filled with mercury alone under a certain pressure, and (b) filled with a known weight (say 100 grammes) of powder and mercury under precisely similar conditions, then, if S be the specific gravity of mercury at the time of experiment, W the weight of globe filled with mercury alone, and W' the weight when filled with powder and mercury,

$$\text{Density} = \frac{S \times W}{W' + 100}$$

5 *Moisture and Absorption of Moisture*.—The amount of water contained in gunpowder is found by drying a carefully-weighed sample in a water oven for a certain period, from the weight lost, when allowed to cool out of contact with the air before weighing, the percentage of moisture can be calculated. The hygroscopic test consists in exposing a dried sample in a box, kept at a uniform temperature, to an atmosphere artificially saturated with moisture, and ascertaining the increase of weight in a certain time.

6 *Penetrating Power*.—The nature of this will depend upon the purpose for which the powder is intended. For sporting powder, it will consist in the "pattern" given by the shot upon a target at a given distance, or, if fired with a bullet, upon the "figure of merit," or mean radial deviation of a certain number of rounds, also upon the penetration it effects through boards. For military purposes the powder is now always fired from the rifle or piece of ordnance with which it is to be used, and the initial or "muzzle" velocity ascertained by the Le Boulenger electric chronograph (see GUNMETER), which measures the exact time the bullet or other projectile takes to traverse a known distance between two wire screens. By means of the "crusher gauges" already referred to, the exact pressure per square inch upon certain points in the interior of the bore can be found, the maximum pressure can be considerably modified by increasing the cubic air spaces given to the charge in the powder chamber. The figure of merit is also taken for small arm powder.

All gunpowder made by or for the British Government is subjected to very strict limits of specification upon all the above-named points.

GUNPOWDER PLOT See FAWKES

GUNS (Hungarian, *Kuszek*), the second town in importance of the Hungarian megye or county of Vas (Eisenburg), near the Styrian frontier, is favourably situated on the Gyongyos, 47° 23' N lat., 16° 31' E long. It is the see of a bishop, and from 1648 until the recent administrative changes of 1876 was a loyal free town. Among the more noteworthy buildings are the cathedral, episcopal palace, a seminary for priests, a gymnasium, the county-hall, a hospital, three monastic houses, a museum of Roman antiquities, a house of correction, and several manufactures of cloth and of earthenware. The agricultural products of the neighbourhood consist principally of fruit and wine, the trade in the latter especially is considerable. In 1870 the number of inhabitants was 6916, mostly of German extraction. The heroic defence of the fortress of Guns by Nicolas Jurek against the army of Sultan Soliman, in August 1532, has given the town a special historical interest. In 1621 it suffered from the attacks of Gabriel Bethlen's troops, and in 1705 the suburbs were plundered and burnt by the forces of Francis Rákóczy. In 1729 and 1777 the town suffered much from fire, and in 1813, 1814, and 1831 from floods. The Esterházy family long held valuable possessions in the neighbourhood, and one of their castles still stands at the northern end of the town.

GUNTER, Edmund (1581–1626), was of Welsh extraction, but was born in Hertfordshire in 1581. He was educated on the royal foundation at Westminster school, and in 1599 was elected a student of Christ Church, Oxford. After graduating bachelor and master of arts at the regular times,

he took orders, became a preacher in 1614, and in November 1615 proceeded to the degree of bachelor in civility. Mathematics, however, which had been his favourite study in youth, continued to engross his attention, and on 6th March 1619 he was appointed to the professorship of astronomy in Gresham College, London. This post he held till his death, which took place on 10th December 1626. With Gunter's name are associated several useful inventions, descriptions of which are given in his treatises on the *Sector*, *Cross staff*, *Bow*, *Quadrant*, and other Instruments. He had continued his sector about the year 1606, and written a description of it in Latin. Many copies were transcribed and dispersed, but it was more than sixteen years after wards ere he allowed the book to appear in English. In 1620 he published his *Canon Trigonometricus*, a table of logarithmic sines and tangents (extended to 7 decimal places) for every degree and minute of the quadrant. In later editions an account of the general use of the canon is prefixed, and Briggs's logarithms of the first 1000 numbers are appended. There is reason to believe that Gunter was the first to discover (in 1622 or 1625) that the magnetic needle does not retain the same declination in the same place at all times. By desire of James I. he published in 1624 *The Description and Use of His Majesty's Dial in Whitehall Garden*, the only one of his works which has not been reprinted. He introduced the words co-sine and co-tangent for sine and tangent of the complement, and he suggested to Briggs, his friend and colleague, the use of the term "logarithmic complement" (see Briggs's *Arithmetica Logarithmica*, cap. xv.). His practical inventions are briefly noticed below.

Gunter's Chain, the chain in common use for measuring land, is 92 yards long and is divided into 100 links. Its usefulness arises from its decimal or centesimal division, and the fact that 10 square chains make an acre.

Gunter's Line, a measuring line, usually had drawn upon scales, was 100 ft. It also called the *line of lines* and the *line of numbers*.

It being only the logarithms graduated upon it, which therefore serves to solve problems instrumentally in the same manner as logarithmic tables arithmetically. *Gunter's Quadrant*, an instrument made of wood, brass, or other substance, containing a kind of stereographic projection of the sphere on the plane of the equinoctial, the eye being supposed to be placed in one of the points so that the tangent, ecliptic, and horizon form the arc of circles, but the hour circle and other circles, drawn by means of several altitudes of the sun for some particular latitude every year. This instrument is used to find the hour of the day, the sun's azimuth, &c., and other common problems of the sphere or globe, and also to take the altitude of an object in degrees.

Gunter's Scale (generally called by about 11 inches broad) is a large plane scale, usually 2 foot long by about 1 1/2 inches broad, and is graduated with various lines of numbers. On one side is, first the natural line (i.e. the line of chords, the line of sines, tangents, secants, &c.), and on the other side the corresponding artificial or logarithmic ones. By means of this instrument questions in navigation, trigonometry, &c., are solved with the aid of a pair of compasses.

GUNTHER, JOHANN CHRISTIAN (1695-1723), German poet, was born at Striegau in Lower Silesia, on the 8th April 1695. After attending the academy at Schweidnitz, where he composed a number of verses of more than usual promise, he entered in 1715 the university of Wittenberg with the view of studying medicine, but he became idle and dissipated, contracted heavy debts, and came to a complete rupture with his father. In 1717 he went to Leipzig, where he obtained the friendship of Menck, and published a poem on the poem of *Facetiae*, which secured him an immediate reputation. Menck recommended him to the king of Poland, but unhappily the first time he appeared at court he was in a state of intoxication. From that time he led an unsettled and dissipated life, depending for an uncertain subsistence partly on money obtained for occasional poems and partly on the charity of his friends. He died at Jena, 16th March 1723, when only in his 28th year. Goethe pronounced Gunther to have been a poet in the fullest sense of the term. As a lyrical poet he stands alone among his contemporaries for freedom, spontaneity, and sincerity of utterance, and his works as a whole give evidence of deep and lively sensibility, fine imagination, clever wit, and a true ear for melody and rhythm. An air of cynicism, however, which was the necessary consequence of his aimless life, is more or less present in most of his poems, and dull, vulgar, or impure wit is not infrequently found side by side with the purest inspirations of his genius.

His collected poems were published in four volumes, Breslau, 1723-1725. They are also included in *Titmann's Deutsche Dichter des 17ten Jahrhunderts*, Leipzig, 1874. A posthumous autobiography of Gunther appeared at Schweidnitz in 1732, and a life of him by Sebastian at Leipzig in 1738. See also Hoffman, *J. Ch. Gunther, ein Leben nach historischer Methode*, Breslau, 1838, and Rogotke, *Leben und Dichten J. Ch. Gunthers*, Stuttgart, 1900.

GUNTOOR, a town in Kistna district, Madras, situated on the Grand Trunk road, about 46 miles from Masulipatnam, 17° 42' N lat., 80° 29' E long., population 18,033. It is the headquarters of the sub-collector and the district judge of Kistna, and there is a considerable trade in grain and cotton. Guntoor was formerly the capital of a Cunar (Sarkar) under the Mahomedans, it was ceded to the French by the treaty in 1753. At the time of the cession of the Cunar to the English in 1766, Guntoor was specially exempted during the life of Basalat Jang, whose personal debt it was. In 1786 it came into British possession, and was finally ceded in 1803.

GURDASPUR, British district in the lieutenant-governorship of the Punjab, lying between 32° 30' and 31° 36' N lat., and between 74° 56' and 75° 45' E long. Bounded on the N. by the native Himalayan states of

Kashan and Chamba, on the E. by Kangra district and the river Bias, on the S.W. by Amritsar district, and on the W. by Sialkot, the district of Gurdaspur occupies the submontane portion of the Bari Doab or tract between the Bias and the Ravi. An intrusive spur of the British dominions runs northward into the lower Himadry ranges, to include the mountain sanatorium of Dalhousie. This station crowns the most westerly shoulder of a magnificent snowy range, the Dholi Dhal, between which and the plain two minor ranges intervene. Below the hills stretches a picturesque and undulating plateau covered with abundant timber, and made green by a copious rainfall, and watered by the streams of the Bari Doab, which, diverted by dams and embankments, now empty their waters into the Bias directly, in order that their channels may not interfere with the Bari Doab canal. The district contains several large and important *jhils* or swampy lakes. Few facts can now be recovered with regard to the early annals of Gurdaspur. Our first distinct historical knowledge begins with the rise of the Sikh confederacy. The whole of the Punjab then was distributed to the chiefs who triumphed over the imperial governors. In the course of a few years, however, the famous Ranjit Singh acquired all the territory which those chiefs had held. Pathankot and the neighbouring villages in the plain, together with the whole hill portion of the district, formed the part of the territory held by the Sikhs to the East India Company after the first Sikh war in 1846. In 1861-62, after receiving one or two additions, the district was brought into its present shape, having its headquarters at Gurdaspur.

Owing to the numerous transfers of territory which took place between the census of 1855 and 1868, it is impossible to give a detailed comparison of their results. The enumeration of 1868 was taken over an area of 1822 square miles, and disclosed a population of 866,126 persons, males, 501,217; females, 364,879. Classified according to religion there are—Hindus, 304,107; Mohammedans, 422,186; Sikhs, 79,387; and others, 101,436. Only six towns have a population exceeding 5000, namely, Batala, 26,807; Dera Muzaf, 7190; Dina Nagar, 5626; Gujranwala, 5556; Lalansar, 6080; and Sargodharpur, 5531. Gurdaspur, the chief town and administrative headquarters of the district, had only 4187 inhabitants in 1875. The sub-station of Dalhousie, 7687 ft. above sea level, though only termed as containing 2019 inhabitants, has a large floating population during the warmer months. The district possesses throughout an excellent soil, except in some small patches on the Bias side, where sand covers the surface. The chief agricultural staples comprise wheat, barley, and gram for the autumn harvest, with rice, pulses, cotton, and sugar cane for the summer crop. About 100,000 acres of ground, where the ground, cultivated from canals, and by a mountain stream, but in no way with the Punjab province can better crops be produced without such artificial aid. In 1875-76 the total cultivated area amounted to 855,675 acres, of which 150,639 acres were irrigated by means generally the effects of drought. The trade of the district consists mainly in the export of its agricultural produce. The imports are insignificant—English piece goods, salt, and fancy articles, forming the main items. The local trade centres on Batala. The principal road of the district connects Amritsar with Pathankot, at the foot of the hills, and passes through Batala, Gujranwala, and Dina Nagar. The total mileage of highways in 1875-76 showed 55 miles of metalled and 205 miles of unmetalled roads. The total population in 1875 was 1,213,608. In 1875-76 the district contained 12 civil and revenue judges, and 14 officers exercised magisterial powers. In the same year the police force numbered 866 men, supplemented by a large body of rural watchmen. In 1875-76 there were 113 schools, having an aggregate roll of 5708 pupils. The climate of Gurdaspur is not unhealthy, but large swamps and excessive irrigation expose some neighbourhoods to malarious fevers and ague. The mean temperature for 1871 was 66° 30' in May and 63° 8' in December at Gurdaspur, and 67° 8' in May and 66° 00' in December at Dalhousie. The average annual rainfall for eight years ending 1875-76 was 86 inches. Seven charitable dispensaries attended about 1875-76 to 89,614 persons.

GURGAON, or GORGAON, a British district in the lieutenant-governorship of the Punjab, between 27° 39' and 28° 30' 45' N lat., and 76° 30' 45' and 77° 35' E long. Bounded on the N. by Rohilk, on the W. and S.W. by portions of the Ulwar, Nabha, and Jind native states, on the

S. by the Muttra district of the North-Western Provinces, on the E. by the river Jumna, and on the N.E. by Delhi, the district of Gurgun comprises the southernmost corner of the Punjab province, and stretches away from the level plain towards the hills of Rājputānā. Two low rocky ranges enter its borders from the south and run northward in a bare and unshaded mass toward the plain country. East of the western ridge the valley is wide and open, and essentially extends to the banks of the Jumna. To the west lies the subdivision of Rewārī, consisting of a sandy plain dotted with isolated hills. Numerous torrents carry off the drainage from the upland ranges, and the most important among them empty themselves at last into the Nālagarh *Mt.* This swampy lake lies to the east of the civil station of Gurgun, and stretches long arms into the neighbouring districts of Delhi and Rohtak. Salt is manufactured from lime in wells at several villages. The mineral products are iron ore, copper ore, plumbago, and ochre. Wolves, leopards, deer, jackals, hares, and foxes are found in the district. In 1803 Gurgun district passed into the hands of the British after Lord Lake's conquests, and under their influence improvements made steady and rapid progress. On the outbreak of the mutiny at Delhi in May 1857, the nabwā of Farrukhnagar, the principal feudatory of the district, rose in rebellion. The Meos and many Rājput families followed his example. A military officer preserved the public buildings and records at Rewārī from destruction; but with this exception, British authority became extinguished for a time throughout all Gurgun. After the fall of the rebel capital, a force marched into the district and either captured or dispersed the leaders of rebellion. The territory of the nabwā was confiscated on account of his participation in the mutiny. Civil administration was resumed under orders from the Punjab Government, to which province the district was formally annexed on the final pacification of the country.

The census of 1881 was taken over an area of 2015 square miles, and it disclosed a population of 698,646 persons—males, 370,281; females, 328,366. The Hindus number 480,307; Mahometans, 215,147; Sikhs, 130; and "others," 62. In 1875-76 there were four municipal towns, with populations as follows:—Rewārī, 25,247; Ferozepore (Ferozpur), 10,580; Patiala, 18,627; Farrukhnagar, 10,611. Gurgun, the administrative headquarters, had in 1868 a population of 5939. Out of a total area of 1,267,335 acres, as many as 967,440 were returned in 1875-76 as under cultivation. The principal products are wheat, barley, *jowar*, *bajra*, gram, oil-seeds, pulses, cotton, and tobacco. Owing to the deficiency of artificial irrigation, Gurgun must always be exposed to drought. Seven periods of dearth have occurred since the disastrous year of 1769. In 1893 and 1897 many villages, according to report, lost their whole population through death and emigration. The traffic of Gurgun district centres entirely upon the town of Rewārī, which ranks as one of the chief trading emporiums in the Punjab. Its merchants transact a large part of the commerce between the states of Rājputānā and the northern provinces of British India. Salt from the Sambhar Lake, together with iron, forms the principal import; sugar and English rice-goods form the chief items of the return trade. In 1871-72 the imports of Rewārī were valued at £208,392, and the exports at £29,028. The means of communication are not of the highest order. One good metalled road traverses the district, from Delhi to Muttra, but the lines of greatest mercantile importance are unmetalled. The Rājputānā State Railway now passes through the district, with stations at Gurgun, Jhām, Jatali, Kalpur, and Rewārī. The total revenue in 1875-76 was £211,885. In the same year 18 civil and revenue judges had jurisdiction, and the police force numbered 605 men, supplemented by a body of village watchmen. The number of schools was 66, with a joint roll of 3660 pupils. The summer heat of Gurgun raises a great interest, and no record of temperature, however, exists. "The average annual rainfall for the eight years ending 1878-4 was 28.52 inches. The district contained 4 charitable dispensaries, affording relief (1876) to 18,034 persons.

GURNALL, WILLIAM (1616-1679), author of the *Christian in Complete Armour*, was born in 1616 at Lynn, Norfolkshire. He was educated at the free grammar school of his native town, and in 1631 was nominated to the Lynn scholarship in Emmanuel College, Cambridge, where

he graduated B.A. in 1635 and M.A. in 1639. Nothing is known of his history from the time that he left the university till 1644, when he was made rector of Lavenham in Suffolk; but it would appear from one of his letters that when he received that appointment he was officiating as minister at Sudbury. At the Restoration he signed the declaration required by the Act of Uniformity, and on this account he was the subject of a libellous attack, published in 1665, entitled *Covenant-Renouncers Deperate Apostates*. He died October 12, 1679, and was buried at Lavenham. The work by which Gurnall is principally known, *The Christian in Complete Armour*, was published in three separate volumes in 1655, 1658, and 1662, and soon became so popular that in 1679 a sixth edition had been called for. It consists of a series of sermons on the latter portion of the 6th chapter of Ephesians, and is more fully described in the title page as a "Treatise of the Saint's War against the Devil; wherein a discovery is made of that grand enemy of God and his people, in his policies, power, seat of his empire, wickedness, and chief designs he hath against the saints;" and a "Magazine from whence the Christian is furnished with spiritual arms for the battle, helped on with his armour, and taught the use of his weapon; together with the happy issue of the whole war." The work is more practical than theological; and its quaint fancy, graphic and pointed style, assisted mingled variety of scriptural application and allusion, and fervent religious tone render it still popular with a certain class of readers.

An *Enquiry into the Life of the Rev. W. Gurnall*, by H. M'Keon, appeared at Woodbridge in 1830, and a biographical introduction by the Rev. J. C. Ryle, chiefly founded on this pamphlet, was prefixed to an edition of the *Christian in Complete Armour* published in London in 1865.

GURNARD (*Trigla*). The gurnards form a group of the family of "mailed cheeks" (*Trigidae*), and are easily recognized by three detached finger-like appendages in front of the pectoral fin, and by their large, angular, bony head, the sides of which are protected by strong, hard, and rough bones. The pectoral appendages are provided with strong nerves, and serve not only as organs of locomotion when the fish moves on the bottom, but also as organs of touch, by which it detects small animals on which it feeds. Gurnards are coast-fishes, generally distributed over the tropical and temperate areas; of the forty species known seven occur on the coast of Great Britain, viz., the red

Trigla pleurocanthios.

gurnard (*T. pinn*), the streaked gurnard (*T. lineata*), the sapphire gurnard (*T. hirundo*), the grey gurnard (*T. gurnardus*), Bloch's gurnard (*T. cuculus*), the piper (*T. byra*), and the long-finned gurnard (*T. obscura* or *T. lucerna*). Although never found very far from the coast, gurnards descend to depths of several hundred fathoms; and as they are bottom-fish they are caught chiefly by means of the trawl. Not rarely, however, they may be seen floating on the surface of the water, with their broad, finely-colored pectoral fins spread out like fans. In very young fishes, which abound in certain localities on the coast in the months of August and September, the pectorals are comparatively much longer than in the adult, extending to the

end of the body, they are beautifully coloured and kept expanded, the little fishes looking like butterflies. When caught and taken out of the water, gurnards emit a grunting noise. Their flesh is very white, firm, and wholesome.

GURWAL See GURWIL

GUSTAVUS I (c. 1496–1560), king of Sweden, commonly known as **GUSTAVUS VASA**, the surname being derived from the family arms, which were a bundle or sheaf, is justly celebrated as the founder of modern Sweden, he delivered it from the yoke of Denmark, introduced the Reformation, established law and order, and laid the foundation of its industrial prosperity. His family name was Ericson, he was born about 1496 of a noble house, and he was related to the powerful family of Sture. Gustavus was at a very early age called upon to suffer for his country. Sweden was still joined to the other Scandinavian kingdoms under the union of Calmar, Denmark being the leading state. Sweden was a reluctant member of this union and King Christian of Denmark was obliged to maintain his suzerainty with a high hand. In an expedition to Stockholm this king treacherously caused off the young Gustavus and other nobles as hostages to Denmark. After being detained in Jutland for above a year, Gustavus managed to escape in disguise to Lubeck, and the great Hanse town, ever jealous of the power of Denmark, furnished him with the means of returning to Sweden, where he landed in 1520. He had now formed the resolution to deliver his country from the oppression of the Danes. He went about from place to place trying to incite the people to revolt, but on all hands he met with apathy and even resistance. For some time his life was in extreme danger, he was hunted by the Danish authorities, and worked in disguise on the farms and in the mines of Dalecarlia. The barn in which he threshed corn is preserved as a state monument. He was on the point of fleeing over the hills into Norway, when tidings came of the Blood bath of Stockholm, in which ninety of the nobles and leading men of Sweden, including the father of Gustavus himself, were executed by the Danish king. This deed roused the slumbering patriotism of the Swedes, especially of the hardy people of Dalecarlia, who now chose Gustavus as their leader (1520). They instantly defeated the Danish forces, and took the principal towns. By 1523 Stockholm was taken and Sweden delivered from the Danish yoke. At a great diet held at Strängnäs in that year Gustavus was elected king of Sweden. Finland was speedily recovered. After liberating his country, Gustavus set himself to the far harder task of reforming and settling it. Sweden was in a very backward and disorderly condition. The nobles had great power and many selfish privileges, the clergy were wealthy, and in the war of freedom had taken the side of the Danes, the peasants were poor and discontented. There was little respect for law, the whole country was demoralised and disorganized. The reforms of Gustavus began with the church. The two brothers Peterson had already introduced the doctrines of Luther, and the chancellor Anderson had translated the New Testament into the native tongue. Vasa encouraged their efforts, in a great diet held at Westerås in 1527 he succeeded under the threat of abdicating in passing measures, by which the lands of the bishops were placed at his disposal, and full liberty was granted of preaching the gospel, but the support of the nobles had to be gained by a share of the spoils. The Reformation soon took deep root, but the troubles of Gustavus continued. He was required to deal with a turbulent nobility, he had to beat off the exiled king of Denmark, three times he needed to pacify a revolt in Dalecarlia, and he was forced to put forth the whole strength of his kingdom to quell a peasants' war in the south. The pretensions of Lubeck, which had given him real help in the war of freedom, and to which he owed a consider-

able sum of money, involved him in a war, by which he curtailed their commercial privileges. In all these difficulties Gustavus bore himself with equal energy and wisdom. In 1544 his position was so acute that the elective sovereignty was changed by the diet into an hereditary one. From this time till his death in 1560, except an unimportant war with Russia on the Finnish frontier, there was little to disturb the quiet progress of Sweden. Gustavus's home policy made an era in Swedish history. Law, order, and national spirit were encouraged and developed, schools were everywhere established, roads made, and foreign trade extended by advantageous commercial treaties with England and Holland. Nothing was too homely or minute for the supervision of the king, he was ready to encourage, scold, or instruct, whenever an opportunity offered in any department of industry. He even established model farms. His second and best-loved queen Margaret had a dairy farm on which twenty-two maidens tended the cows. While he avoided foreign war he did not neglect national defence, he left an excellent army of 15,000 men, and he created a considerable naval force. Altogether, few kings have done so much for any country as Gustavus Vasa did for Sweden. He was succeeded by his son Eric.

See *Geyser's History of the Swedes*, also an anonymous *History of Gustavus Vasa*, London, 1852.

GUSTAVUS II, or **GUSTAVUS ADOLPHUS** (1594–1632), the hero of Protestantism in the Thirty Years' War, and the first king of Sweden who played a great rôle in European history, was the grandson of Gustavus Vasa, and the son of Charles IX. He was born at Stockholm in 1594, and received an excellent education. As we learn from his friend and chancellor Oxenstierna, he gained in his youth "a complete and ready knowledge of many foreign languages, so that he spoke Latin, German, Dutch, French, and Italian as purely as a native, and besides had some knowledge of the Russian and Polish tongue." Even during his busiest years, after ascending the throne, it is said that he was fond of reading the great work of Grotius, *De Jure Belli et Pacis*, also that he knew Greek, preferring Xenophon as a military historian to any other. He was introduced to the business of government at an early age, when he was only ten, his father required his presence at meetings of council and at the audiences given to foreign ambassadors. Thus early experience was needed, for his father dying in 1611, he ascended the throne of Sweden in his eighteenth year. His position was a difficult one, after fifty years of civil strife, Sweden had lost the strong and compact organization which it had received from Gustavus Vasa, the finances were exhausted, the nobles were discontented, and the spirit of the people had declined. Abroad, Sweden was surrounded with enemies, Denmark, Russia, and Poland being in a state of chronic hostility with it.

To the difficult task before him the young king applied himself with equal skill and resolution. He attached the nobles to himself by his respect for their privileges and his genial manner, showed them a more honourable field of activity in a patriotic war, and even induced them to bear their due share of its financial burdens. The administration was reformed in all its branches, industry encouraged, and education greatly improved. In this way the national spirit was wonderfully raised, and Sweden was gradually prepared to play for the first time a great part in Europe,—a part which seemed so disproportionate to her natural resources. At his accession Gustavus was engaged in a difficult war with Denmark, which, besides its supremacy over Norway, occupied what is now southern Sweden. The peace of 1613 left their respective frontiers very much as they had been before the war. The war with Russia ended much more advantageously for Gustavus in the peace of Stolbovo (1617), by which Sweden was confirmed in the possession

of the Baltic provinces stretching from Finland to Livonia. Gustavus clearly foresaw the advantage to himself and the danger to Sweden if the former power were allowed to plant itself on the Baltic coast, and he now congratulated his country on a peace which assured her against such a risk. In 1620 Gustavus married a sister of the elector of Brandenburg, with whom he lived happily till his death. After being for many years engaged in an intermittent war with Poland, Sweden (1621) entered upon a more active conflict with that power. With some interruptions the struggle lasted till 1629, and proved an excellent training for Gustavus. Sigismund, king of Poland, was his cousin, and had at one time been king of Sweden, but had been forced to resign owing to his Catholic opinions. He still laid claim to the crown of Sweden. In this war Gustavus took Riga, and made many other conquests in Livonia as well as in Courland and Prussia, part of which he retained by the peace of Altmärk, concluded under the mediation of Richelieu.

That great statesman wished to get Gustavus's hands free for a more important conflict, in which the king himself had long been eager to engage. While Gustavus had been involved in his Baltic war, the Catholic house of Austria had been swiftly raising itself on the ruins of German Protestantism to a position of absolute supremacy. In this early period of the Thirty Years' War, which dates from 1618, the arms of Protestantism had been everywhere overthrown by Tilly and Wallenstein. The latter, raising a host at his own cost and bearing desolation wherever he went, garrisoned Brandenburg and Pomerania, occupied Mecklenburg, and overran the continental dominions of Denmark. The only town that successfully resisted the imperial general was Stralsund, the king of Denmark was obliged to make peace. Such a colossus, with its gigantic force of oppression and devastation and its invincible armies, Gustavus now ventured to attack. It seemed a foolhardy undertaking which excited the laughter of his enemies, when in mid-summer 1630 he landed on the coast of Pomerania with his little army of 15,000 men. Yet there were many things in his favour,—the despair of the Protestant princes, who saw a great part of their lands threatened by the Edict of Restitution, the disunion of the Catholics, who forced the emperor to dismiss Wallenstein shortly after the landing of Gustavus, the help of Richelieu, who now inaugurated the French policy of weakening Germany by dividing it. This help was formally assured him by the treaty of Bawalde (January 1631). Yet the German princes showed no haste to join Gustavus, the duke Boguslaw reluctantly consented to receive the Swedish army into his capital—Stettin. But the marvellous discipline of the Swedes, so different from the wild barbarism of the imperial army, soon gained the confidence of the German people, robbery and licence were unknown, morning and evening the soldiers assembled for prayer round their regimental chaplains, such an army had never been seen in Europe. It was not less distinguished for its laudable bravery in war, keeping the field in winter as well as summer, it soon drove the imperialists out of Pomerania and the lower basin of the Oder, and stormed Frankfort-on-the-Oder. In the midst of those successes, Gustavus was greatly moved by the sack of Magdeburg (May 1631). Fearful of being cut off from his basis of operations, he could not advance to the relief of the city without the cooperation or consent of the electors of Brandenburg and Saxony. During the delay thus caused, Magdeburg was taken by Tilly, and became a scene of the most fearful atrocities. Too late Gustavus forced the elector of Brandenburg to hand over to him the fortresses required, a desolating invasion of Saxony by Tilly compelled even the Saxon elector to seek the aid of Sweden. The union of the Swedish and Saxon forces was followed

by the battle of Breitenfeld (near Leipzig), in which Tilly was completely overthrown, and the supremacy of Catholic Austria shattered at a single blow (Sept. 1631). While the Saxons overran Bohemia, Gustavus, now hailed as the liberator of Protestantism, marched westwards towards the Rhine, gathering round him the friendly Germans, and driving out the imperial garrisons. Wurtzburg and Frankfort were occupied, at Oppenheim he forced the passage of the Rhine against the Spaniards, he spent Christmas in the ecclesiastical city of Mainz. Early next spring he advanced into Bavaria, forcing the passage of the Lech in the face of Tilly (who was mortally wounded). Munich had to pay a war contribution to the Swedes.

In this overwhelming reverse of fortune, the emperor Ferdinand was obliged to invoke the aid of Wallenstein, who soon changed the course of the war. He gathered a mighty host, cleared the Saxons out of Bohemia, and marching westwards threatened the wealthy city of Nuremberg. Afraid of a repetition of the horrors of Magdeburg, Gustavus hastened northwards and threw himself into the city with a small force. In the neighbourhood Wallenstein threw up a fortified camp resolving to starve his rival out, and here the great captains watched each other for several weeks. After drawing his scattered forces together, Gustavus offered battle to the enemy, and when that was declined he assailed his intrenched position, but without effect. Leaving a sufficient garrison to defend the exhausted city, he advanced a second time into Bavaria, where he hoped to draw Wallenstein after him, and thus transfer the seat of war to the enemy's country. But Wallenstein made a desolating march through Thuringia into Saxony, which he resolved to make his winter quarters, and again Gustavus was obliged to leave his Bavarian conquests to save his ally from such a cruel guest. On a misty November day (1632) he attacked the army of Wallenstein at Lützen (near Leipzig). The numbers engaged were not great according to Ranké, the Swedes were 14,000, the imperialists only 12,000 at the beginning of the conflict, but the battle was one of the fiercest recorded in history. The Swedes had carried the strong positions of the enemy and turned his own cannon against him, when the cavalry of Pappenheim, which had left the main army shortly before the battle, appeared on the field. The Swedes were hurled back, and the king, too eagerly hurrying forward to reform the battle, was separated from his guards and shot. Wild with rage and sorrow the Swedes renewed the attack, overthrew the enemy, and won his artillery again. Without making any effort to recover it, Wallenstein retreated into Bohemia, while the Swedes carried the disfigured body of their king from the battlefield. It was laid to rest in the Riddarholm church at Stockholm.

Gustavus Adolphus is justly regarded as one of the noblest and greatest figures in history. Even in the art of war he made an epoch. To the huge and unwieldy masses of Tilly he opposed a light and flexible formation of three deep, which he manoeuvred with unwonted rapidity. The activity of his movements was equalled by the dexterity with which his artillery and muskets were handled, at Leipzig his guns fired three shots for the enemy's one. The political plans which Gustavus entertained have been the subject of some discussion. That he aimed at founding a Swedish empire of the Baltic, and succeeded in doing so, is certain, he meant also to unite under his protection the *corpus evangelicum* of Germany. Probably too he seemed to become a candidate for the empire, and if so, he had only one disadvantage, that he was a foreigner. Even with this drawback it would have been the best course available for Germany, to have enjoyed for a generation the rule of such a man would have been an unspeakable blessing, at any rate infinitely better

than the supremacy of Austria, or that process of desolation and ruin which actually took place. In any case his premature death at the age of thirty eight was an irreparable loss for German Protestantism. The Thirty Years' War, which for two years had been rendered heroic by his presence, degenerated again into a scene of the wildest barbarism, by which Germany was reduced to a wilderness, and flung back at least a century in the march of civilization.

Schiller's *Guardschichte des dreissigjährigen Kriegs* is a brilliant production, but written without a careful study of the sources. (T. K.)

GUSTAVUS III. (1746-1793), king of Sweden, succeeded his father Adolphus Frederick at the age of twenty-five. He was in Paris when his father died, and was an enthusiastic admirer of everything French. His manners were popular, he was brave, resolute, and eloquent. At the beginning of his reign he found the royal power completely overshadowed by the nobles, who in the council virtually dictated the government of the country, and had involved it in frequent disturbance and disgrace. A revolt, contrived for this purpose by one of his adherents, gave Gustavus a pretext for marshalling his guards, whom he won over and employed to make a complete change in the constitution. As the nobles were disliked by the people, they were obliged to submit. Surrounded by soldiers, the diet accepted the new form of government, by which the entire administrative power including taxation was entrusted to the king. In many respects Gustavus made an excellent use of his great power, he improved the army and navy, reformed the administration of justice, abolished torture, and built hospitals. But his foolish aping of French fashions, and his dream of leaving the knightly exercises and accomplishments, led him into great extravagance. His arbitrary attempt to introduce a national dress, as well as the conviction of bandy, the national drink of Sweden, into a royal monopoly, lost him his popularity. In 1788 in his campaign against Russia, several nobles, officers of his army in Finland, refused to carry on the war because it had not been sanctioned by the estates. Angry at this Gustavus summoned the hardy Dalecarlians to his aid, deprived the nobles of their exclusive privileges, and made his power absolute. He continued the Russian war with great bravery and even success till the peace of 1790, which made no change on the Finnish frontier. Gustavus's next project, which he prosecuted with his usual energy and disregard of consequences, was a war to save King Louis XVI. from the Revolution. This war the estates, already weary of his expensive undertakings, refused to support. To avert a new *coup d'état* some nobles formed a conspiracy against him, and Ankarström, formerly an officer in the guard, shot him at a masked ball at Stockholm (1792).

GUSTAVUS IV. (1778-1837), king of Sweden, was son of the preceding. He was only fourteen years of age when his father was cut off, and his uncle Duke Charles acted as regent during the minority. Gustavus early gave proof of an obstinate strength of will and of a highly-wrought temperament bordering on insanity. Thus he went to St. Petersburg, according to agreement, to marry a granddaughter of the emperor Catherine, and the whole court was assembled for the ceremony. The bridegroom however did not appear, and the company dispersed after waiting several hours. Gustavus had drawn back at the eleventh hour, refusing to sign the marriage treaty because it bound him to grant his future queen the free exercise of

her religion. He spent his whole reign under the mastery of a fixed idea, that Napoleon was the Great Beast spoken of in the Apocalypse, and he joined the great coalition of 1805 against the conqueror. In this war Swedish Pomerania was occupied by the French. Even after Tilsit, Gustavus prosecuted the war with unbroken resolution. Sweden suffered fearfully by this obstinacy of the king, the Russians conquered Finland, the Danes invaded the southern provinces, his English allies, wearied of his irrational obstinacy, left him to his fate. Sweden also grew sick of his wrong-headed policy. The officers of the army conspired against him. He was dethroned and detained in captivity, while his uncle Duke Charles was elected to the crown (1809). After the new arrangements had been made, he was banished with the assurance of a considerable income. Under the name of Colonel Gustavson he passed a wandering life abroad, dying at St. Gall in 1837.

GUSTAVUS ADOLPHUS UNION (GUSTAV-ADOLF-STIFTUNG, GUSTAV-ADOLF-VEREIN, EVANGELISCHER VEREIN DER GUSTAV-ADOLF-STIFTUNG), a society formed of members of the Evangelical Protestant churches of Germany, which has for its object the aid of feeble sister churches, especially in Roman Catholic countries. The project of forming such a society was first broached, in connection with the bi-centennial celebration of the battle of Lützen, on the 8th of November 1832, a proposal to collect funds for a monument to Gustavus Adolphus having been agreed to, it was suggested by Superintendent Giesemann that the best memorial to the great champion of Protestantism would be the formation of a union for propagating his ideas. For some years the society was somewhat limited in its area and operations, being practically confined to Leipzig and Dresden, but at the Theofestival in 1841 it received a new impulse through the energy and eloquence of the Hofprediger Zimmermann of Darmstadt, and in 1843 a general meeting was held at Frankfurt-on-the-Main where no fewer than twenty-nine branch associations, belonging to all parts of Germany except Bavaria and Austria, were represented. The want of a positive record on the part of the Union tended from the first, however, to make many of the strictest Protestant churchmen doubtful of its probable usefulness, though on the other hand its purely negative attitude in relation to Roman Catholicism secured for it the sympathy of the masses. At a general convention held in Berlin in September 1846 a keen dispute arose about the admission of the Königsberg delegate Rupp, the founder of the "Free Congregations," his exclusion, which was carried by a majority, called forth many energetic protests, and at one time it seemed likely that the society would be completely broken up. A peaceful solution of the difficulty, however, was reached at Darmstadt in 1847. Amid the complications of the Revolution of 1848 the whole movement fell into stagnation, but in 1849 another general convention (the seventh), held at Breslau, showed that, although the society had lost both in membership and income, it still was possessed of considerable vitality. From that date the Gustav-Adolf-Verein has been more definitely "evangelical" in its tone than formerly, and under the direction of Zimmermann of Darmstadt it has greatly increased both in numbers and in wealth. In 1863 the income was £13,500, in 1885 it had risen to £31,000, while in 1876 there was divided among 1406 congregations a sum of nearly £35,000. The total number of congregations assisted up to that date was 2553, and the sum distributed amounted to an aggregate of nearly £637,000. Apart from any influence it may have had in advancing the cause of Protestantism in places where it was struggling or weak, there can be no doubt that the Union has had a very great effect in helping the various separate Evangelical churches of Germany to

realize the number and importance of their common interests. It ought to be added that the strictest Lutherans still continue to hold aloof from it.

The Verein has numerous special organs, of which the most important are the *Darmstädter Bote des Evangelischen Vereins d. hiesiger Adolf-Stiftung und Pflegenden Blätter*. See *Zimmermann's Geschichte des Gustav Adolf-Vereins*, Darmstadt, 1868.

GUSTROW, the chief town of the Wendian circle of the grand duchy of Mecklenburg-Schwerin, Northern Germany, is situated on the Nebel and on the railway from Lubeck to Stettin, 20 miles south of Rostock. The principal buildings are the castle, erected in the middle of the 16th century, now used as a workhouse, the cathedral, dating from the 13th century, and lately renovated, containing many fine monuments and possessing a square tower 100 feet high, the town-hall, dating from the 16th century, the court houses, the music hall, and the theatre. Among the educational establishments are the ducal gymnasium, which possesses a library of 15,000 volumes, the town school, the city school, the trade school, and four female schools. The town is one of the most prosperous in the dukedom, and has breweries, foundries, tanneries, sawmills, brandy distilleries, and manufactures of tobacco, glass, candles, and soap. There is also a considerable trade in wool, corn, wood, butter, and cattle, and an annual cattle show and horse races are held. Population (1875), 10,923.

Gustrow was a place of some importance as early as the 12th century, and in 1219 it became the residence of Prince Henry Bismarck II., from whom it received Schwerin privileges. From 1566 to 1866 it was the residence of the dukes of Mecklenburg-Gustrow. In 1698 it was occupied by the imperial troops, and Wallenstein resided in it during part of the years 1628 and 1629.

GUTENBERG, JOHN, was born about 1410 at Mainz of noble parents, his father being Friezo von Gansfleisch, and his mother, whose name he adopted, Elise von Gutenberg. In 1420 the citizens of Mainz drove the patricians out of the city, and as Gutenberg's name appears about ten years later at Staßburg the family probably took refuge there. When the expelled families were recalled to Mainz, Gutenberg did not avail himself of the privilege. We next hear of him at Straßburg, where in 1484 he seized and imprisoned the town clerk of Mainz for a debt due by the corporation of that city, releasing him, however, at the urgent representations of the mayor and counsellors of Staßburg. In 1497 Gutenberg was sued before the ecclesiastical court by Emmeline zu Isenre Thure for breach of promise of marriage, the case being settled by his making her his wife. The active mind of Gutenberg had adopted several plans for making money before he invented the art of printing with movable types, which is his great claim upon the gratitude of mankind. Before 1425 he engaged in some experiments requiring money, when Andrew of Ditzheim, a fellow-citizen, became security for him, and the same year a partnership between them was arranged to carry out Gutenberg's new plan for polishing stones. Next came an improvement in the manufacture of looking-glasses, for which money was lent by other two friends. For these a lucrative sale was expected at the approaching pilgrimage to Aix-le-Chapelle, which, however, was unfortunately postponed. In 1438 was arranged a partnership between Gutenberg, Andrew Ditzheim, Andrew Heilmann, and Anton Heilmann, and that this concerned the new art of printing appears from the long law proceedings which soon after followed. The action was brought by the brothers of Ditzheim, who were dead, to force Gutenberg to reveal the secrets of the partnership. The decision was in favour of Gutenberg. In January 1441 Gutenberg obtained 80 livers by mortgaging some house property, and again in 1442 he borrowed money of Martin Brähler for carrying on his experiments. For four years after this nothing is known of Gutenberg except that his wife paid taxes

in his name. He now returned to his native city, Mainz, where he borrowed 100 guilders of his kinsman Arnold Gelthus, and established himself in the house Zum Jungen, which was part of the family possessions. At this time Gutenberg must have been able to show some solid and convincing results of his new invention, for he obtained substantial aid from a shrewd goldsmith, John Fust or Faust, who advanced 800 guilders to promote the work, taking as security a mortgage on all the printing materials to be purchased. Gutenberg at once set to work upon a large folio Latin Bible, the printing of which was ended before August 1455. During the progress of this great undertaking several forms of indulgence and other small things were printed, the earliest with a date being the Indulgence of 1454 in the library at Althorp. But the new art was certainly not a success commercially, and again Fust had to come forward with another 800 guilders to prevent a collapse. In November 1455 Fust determined to dissolve his connexion with Gutenberg, and demanded payment of his advances. Gutenberg not being able to refund so large a sum, Fust took legal proceedings against him, and he was eventually compelled to yield up the whole of the printing materials, which at once were removed by Fust to his own house at Mainz. Here with the assistance of Peter Schoffer he continued to print until the sack of the city in 1462 by Adolphus II. Gutenberg, however, in the evening of life, had to make a fresh start in the world, and fortunately in Dr. Humery of Mainz found a friend who assisted him with capital. Embarrassment, however, still pursued him, and the press made slow progress. It is uncertain whether the new press of Gutenberg was in Mainz or at the neighbouring town of Eltville. On January 17, 1465, Gutenberg accepted the post, at the court of Archbishop Adolphus, of salaried courtier. He received annually a suit of livery together with a fixed allowance of coin and wine. Meantime the printing materials were lent to the brothers Bechtelmannze, who printed some inconsiderable works, and upon the death of Gutenberg were claimed and taken by Dr. Humery. On February 2, 1468, died Gutenberg, poor, childless, and almost friendless, after laying the foundations of an art which was soon to dominate the world. Arnold Gelthus erected a monument to his memory near his grave, and forty years afterwards Ivo Wittig set up a memorial tablet at the legal college in Mainz.

No portrait of Gutenberg is known, those appearing upon medals, statues, or engraved plates being all fictitious. The latest authority upon his life and work is *Gutenberg*, by Dr. Van der Linde.

GUTHRIE, THOMAS (1803-1873), Scottish clergyman and philanthropist, was born at Brechin, Forfarshire, on July 12, 1803. He entered the university of Edinburgh at the early age of twelve (November 1819), and continued to attend classes there for more than ten years. During that period he seems to have read widely in general literature, although he did not distinguish himself as a student in the strict sense. On the 2d of February 1825 the presbytery of Brechin licensed him as a preacher in connexion with the Church of Scotland, but it was not till 1830 that he was inducted to his first charge, Arbuthnot, in Forfarshire, where he laboured for seven years. In 1837 he became the colleague of the Rev. John Sym in the pastorate of Old Greyfriars, Edinburgh, and at once attracted notice as a great pulpit orator. Towards the close of 1840 Guthrie was chosen minister of St. John's Church, Victoria Street, Edinburgh. His increasing popularity brought him flattering invitations both from London and from India, but these he firmly declined. He was an enthusiastic supporter of the movement which led to the Disruption of 1843, and his name is thenceforth associated with the Free Church. In 1847 he began the

greatest work of his life by the publication of his first *Plea for Ragged Schools*. This pamphlet, amid a multitude of other encomiums, elicited a beautiful and sympathetic letter from Lord Jeffrey. A ragged school was opened on the Castle Hill, which has been the parent of many similar institutions elsewhere. Guthrie insisted on bringing up all the children in his school as Protestants, and he thus made his ragged schools not only educational but proselytizing institutions. This interference with religious liberty led to some controversy, and ultimately those who differed from Guthrie founded the United Industrial School, which is managed on the principle of combined secular and separate religious instruction. In April 1847 the degree of D.D. was conferred on Guthrie by the university of Edinburgh, and in 1850 Dr Hanna, the laicophiler of Dr Chalmers, was inducted as his colleague in Free St John's Church.

In 1850 Guthrie published *A Plea on behalf of Drunkards and against Drunkenness*, which was followed by *The Gospel in Ezekiel* (1856), *The City, its Sins and Sorrows* (1857), *Christ and the Influence of the Saints* (1858), *Seclerism and the Loss of Ragged Schools* (1860), consisting of his three *Plea for Ragged Schools*, and *The Way to Life and Speaking to the Heart* (1863). These works had an enormous sale, and earned his fame to distant parts of the world. Portions of them were translated into French and Dutch. In 1862 he was moderator of the Free Church General Assembly, but he seldom took a prominent part in the business of the Church courts. In connection with the total abstinence movement he often appeared on the platform, where his oratorical talents, rich humour, genuine pathos, and inimitable power of story-telling eminently qualified him to shine. He was also greatly interested in the work of the Evangelical Alliance, of which he was one of the vice-presidents. In 1861, his health being seriously impaired, he resigned public work as pastor of Free St John's (May 17), although his nominal connexion with the congregation ceased only with his death. Guthrie had occasionally contributed papers to *Good Words*, and, about the time of his retirement from the ministry, he became editor of the *Sunday Magazine*, himself contributing several series of papers which were afterwards published separately. In 1860 he was presented with £5000 as a mark of appreciation from the public. His closing years were mostly in retirement, and after an illness of several months' duration he died at St Leonard-on-Sea, February 24, 1873.

Dr Guthrie's fame rests on his labours as a social reformer and his extraordinary oratorical power as a preacher and platform speaker. He will always be remembered as one of the most successful and warm-hearted of Christian philanthropists, and his influence over the masses of his countrymen was very great. His theology was the moderate Calvinism generally accepted by the Evangelical school. His style is distinguished by great graphic power and richness of illustration, but, although admirably adapted for effect on a popular audience, it is far too florid and Asiatic in its rhetoric to please a sound literary critic.

See *Autobiography of Thomas Guthrie, D.D., and Memoirs* by his son, 2 vols., London, 1874-5.

GUTS MUTHS, JOHANN CHRISTOPH FRIEDRICH (1759-1839), a German teacher and the principal founder of the German school system of gymnastics, was born at Quedlinburg 9th August 1759. He was educated at the gymnasium of his native town and at Halle university, and in 1785 he went to Schnepfenthal, where he taught geography and gymnastics in Salzmann's academy. His method of teaching gymnastics was expounded by him in various hand-books; and it was chiefly through them that gymnastics very soon came to occupy such an important position in

the school system of Germany. He also made much to introduce a better method of instruction in geography. He died May 21, 1839.

His principal works are *Gymnastik für die Jugend*, 1793, *Spiele zur Übung und Erhaltung des Körpers und Geistes für die Jugend*, 1794, *Turnbuch*, 1817, *Handbuch der Geographie*, 1810, and a number of books constituting a *Bibliotheca für Pädagogik, Schullehre, und die gesamte pädagogische Literatur Deutschlands*. He also contributed to the *Vollständiges Handbuch des neuesten Bildhauers*, 1809, and, along with J. A. Schenk, published *Deutsches Land und deutsches Volk*, the first part, *Deutsches Land*, being written by him.

GUTTA PERCHA (GUTTA TABAN, &c.) This name¹ is applied to the constricted or inspersated juice of various plants belonging to the natural order *Sapotaceae*, growing in the Malay Peninsula. To what particular tree the name "gutta percha" properly belongs, there is no evidence to show, but it has been generally given to *Duchospora Gutta* (Bentley and Timen) or *Leocordia Gutta* (Hooker), the vernacular name of which is "taban"².

The *Duchospora Gutta* attains a height of 60 to 80 feet, with a diameter of 2 to 4 feet. The leaves are ovate-oblong and entire, pale green on the upper side, and covered beneath with short reddish-brown shining down. The flowers are arranged in clusters of 3 or 4 in the axils of the leaves. The fruit, about an inch long, is of an ovoid shape, and is eaten by the Malays. In Siam (Siam) a vegetable butter is prepared from the seeds. The wood is soft, fibrous, spongy, of a pale colour, and marked with black lines, those being reservoirs of gutta percha.³ The gutta, as it flows from the tree, is of a greyish hue, occasionally with a somewhat roseate tinge, probably arising from the colour vessels of the bark becoming ruptured through swarms, and thus contents mixing with the gutta. This species does not furnish all the gutta percha of commerce, indeed there are other trees which yield larger quantities. In all these are about thirty varieties known, but some of the vernacular names in different districts may prove more synonyms.

The geographical distribution of the trees producing gutta percha is very restricted. Gutzlaff defines the limits as 6° N and 8° lat and 100° to 120° E long, whilst Captain Langard (who has great personal experience on the subject) gives the limits as 4° N and 3° S lat, still further restricting the area varieties to 3° 50' N and 1° S, with a temperature ranging between 66° and 90° Fahr, and a very moist atmosphere. These limits are well within the isotherm of 80° Fahr. Many of the best varieties are found only on the hill slopes at a distance from the sea coast, each variety forming a separate grove of from 200 to 500 trees, with high forest trees above them. They grow best in a rich light loam, with a rocky subsoil.

The collection of gutta percha generally takes place directly after the rainy season, as in the dry season the gutta does not flow so readily, while during the rains egges and jungle fever are most prevalent, and the gutta is liable to be washed away from the felled trees. The yield of a well-grown tree of the best variety is from 2 to 3 lb of gutta percha, such a tree being about thirty years old, 30 to 40 feet high, and 1½ to 3 feet in circumference. A full-grown tree sometimes measures 100 to 140 feet to its first branches.

¹ Gutta, or as it is variously written gutah, gutta, gutih, gitta, is the Malay name for gum, and Percha (pronounced as in perch, not hard as perch), accentuated variously as pincha, peria, percha, is the name of the tree, hence the term may be translated "gum of the percha tree." The old name of Bunnia was Palo or Pulan Percha, i.e., "solid (Pulan) of the percha tree."

² Taban, taban, tabun is the name of the tree, and, according to Logan, a new word has been added to the Malay language, viz., Mamban (Mam[ph]an), i.e., to collect gutta taban. The greater number of Malay names admit of conversion into verbs by a prefix.

³ For figures and botanical descriptions see *London Journal* No. 1848, De Vries, *De Handel in Guttapercha*, and Bentley and Timen's *Medicinal Plants*, part 85, p. 16 (1878).

with a girth of 20 feet at a distance of 14 feet from the base, and may yield 50 to 60 lb of gutta percha, which loses in six months about 35 per cent of its weight in drying.

The methods of extracting the gutta percha are much the same amongst the Malays, Chinese, and Dyaks. The trees are cut down, just above the buttresses, or *bances*, as they are called, and for this purpose a staging about 14 to 16 feet high is erected. The tools used in felling are either "billhooks" or "jangs". A billhook is a kind of axe used by the Malays in felling, building, &c. The blade is of a chisel like form, and the tang is scooped at right angles to a handle by means of a jangling of "retan" or cane. The Chinese sometimes use an axe perfectly wedge-shaped. The parang looks more like a sword-bayonet, and in the hands of a Malay is a box of tools in itself, as with it he can cut up his food, fell a tree, build a house, or defend himself.

When the tree is felled the branches are speedily lopped off, to prevent the ascent of the gummy latex to the leaves. Narrow strips of bark, about an inch broad and 6 inches apart, are then removed, but not all round the tree, as its support in its fall becomes buried in the soft earth, much sap being thus lost. Some natives beat the bark with mallets to excite the flow of milk or gutta. The milk flows slowly (changing colour the while) and rapidly coagulates, and, according to its source, may vary from yellowish-white to reddish or even brownish in hue. The gutta as it flows is received into hollow bamboos, doubled-up leaves, 'spaths of palms, pieces of bark, cocoa-nut shells, or in holes scooped in the ground. If the quantity obtained is small, it is prepared at the spot by rubbing it together in the hands into a block, in one end of which a hole is made to carry it by. In this state it is known in the markets as "raw gutta" or "gutta muntah." If water gets mixed with the juice, the gutta becomes stringy and is considered deteriorated, but after boiling appears quite as good. Sometimes the gutta is kept in a raw state for a month or two, and then undergoes the next step in the preparation, that is, boiling. The boiling is generally conducted in a "kuali" or pan of cast or hammered iron, of about 10 inches in diameter and 6 inches deep. The boiling is either simply with water, or with the addition of lime juice or cocoa-nut oil. If one pint of lime juice be added to three gallons of gutta juice, the latter coagulates immediately on ebullition.

On arriving at the point of shipment the gutta, before exportation, generally undergoes examination and classification into parcels, according to quality. As received in the "godowns" or warehouses it presents great diversities in condition, shape, size, and colour,—from crumbling, hardy coherent, whitish or greyish "raw" or "getah muntah" fragments, to reddish or brownish blocks as hard as wood. Sometimes it is made up into all manner of grotesque shapes of animals, and it is mostly always largely adulterated with sawdust, wax, resin, clay, stones, &c. The Chinese are great adepts in assorting and classifying gutta, and frequently procure from different varieties a certain "standard sample" by cutting or chopping the material into thin slices and boiling with water in large shallow iron pans, keeping the contents constantly stirred with poles, and adding good gutta percha and even cocoa-nut oil to give a better appearance. When sufficiently boiled the gutta is pressed into large moulds, and is then ready for shipment. This process of reboling is wholly unnecessary, and in some cases is done only to get rid of stuff which has no right to be called "gutta percha."

The amount and value of gutta percha imported into Great Britain in 1875-76 were as follows—

	1875	1876	1877
Cwt.	10,668	21,568	26,859
Value	£119,084	£169,441	£228,327

The price of gutta percha ranges from 4d to 3s per lb, according to quality and demand.

History.—The early history of the use of gutta percha is somewhat obscure, the Malays and Chinese are said to have long known and used it. One of the earliest notices of it in England occurs in a catalogue of the collection of the famous Tridacens.¹ Dr Montgomerie, a surgeon in the East India Company's service, was the first to direct attention to gutta percha as likely to prove of great utility in the arts and manufactures. Having observed the substance in Singapore in 1822 in the form of whips, he commenced experimenting with it. In 1842, being again stationed at Singapore, he followed up the subject, and his recommendation of it to the medical board of Calcutta was useful for making of splints and other surgical appliances met with high approval. He also sent specimens, with relative information, to the Society of Arts of London, which society warmly took up the subject, and on Montgomerie's return to England in 1844 presented him with its gold medal. Some have claimed the honour of introducing gutta percha to the notice of the commercial world for Dr (afterwards Sir) Jose D'Almeida, who sent a specimen merely as a curiosity to the Royal Asiatic Society in 1843, but careful investigation clearly decides the question of priority in favour of Montgomerie. The Society of Arts having requested him to lay before them the result of his experiments, he delivered a lecture in the summer of 1844, and many patents were at once taken out by the names of those of M. C. Hancock, Mr Nickels, Mr Keene, Messrs Barlow and Forster, Mr E. W. Siemens, and others. After this the substance soon came into general use.²

Properties.—Gutta percha, like many other milky juices, occurs in the laticiferous tissue of the plant, which exists in greatest abundance in the middle layer of the bark. See Botany, vol. iv p. 87.

Gutta percha is resolvable into two isomers, *albin* and *fluviid*. Lake crithone or milky rubber, it is a hydrocarbon, $\text{C}_{10}\text{H}_{16}$ gives its composition as—carbon 87.80 and hydrogen 12.20. In commercial gutta percha we have this hydrocarbon in pure gutta, plus a soft resin, a solvent of oxidation of the hydrocarbon. Mr Payson gives the following analysis of commercial gutta percha—

Pure gutta (milk white in colour and fusible), 75 to 82 per cent. Resins soluble in boiling alcohol—

1. Crystalline or albin ($\text{C}_{10}\text{H}_{16}$), white, and crystallizing out of the alcohol as it cools, 6 to 14 per cent.

2. Fluviid ($\text{C}_{10}\text{H}_{16}$), yellow, fusing as an amorphous powder on the cooling of the alcohol, 1 to 14 per cent.

It is thus apparent that the change of pure gutta into a resin like mass takes place naturally if means be not taken to stop it. Many a good piece has been thus lost to commerce, and the only remedy seems to be through boiling as soon after collection as possible. It must be remembered too that, in cutting through the bark to arrive at the laticiferous vessels, many other vessels and cells are punctured, containing tannin and gallic acids, &c., and the presence of these we denote by a colorless oxidation. In opening bottles of the milky juice a turbidity and effervescence are often noticed, owing to the formation of a brownish liquid, the colour being probably due to the presence of gallic acid. In impurely prepared blocks of gutta also, these foreign substances reduce the presence of a brown fermented and putrid liquid, which decomposes the internal mass. Many of these substances, being soluble in water, are removable by the process of boiling.

Gutta percha as met with in commerce is of a reddish or yellowish hue, but when quite pure is of a greyish-white colour. In this

¹ In the *Museum Tridacensium*, or, a Collection of the true *Tridacens* given and at South Lambeth, near London, by John Tridacens, London, xxcvii., the following entry occurs (p. 44)—"VIII. Variety of Rubber.—The phylloid mass, being warmed, will yield to any force." This mass was the unknown of the Ashmolean Museum at Oxford. The word "mass," variously spelt, often occurs in early English poetry, and is specially mentioned in old entomology and will. It is by no means impossible that masser cups may have been made of gutta percha, as its lightness, strength, and non-solubility in fire would recommend it, and eventually, could one of the venacular names of the tree yielding gutta percha is "masser wood tree."

² See Collins on "Gutta Percha" in *British Manufacturers' Industries* (Standard & Co.), and the very interesting volume of *Singapore Patent* in *Colonial*, Gutta Percha, &c. issued by the Patent Office.

state, it is usually as hard as wood, only just retaining the impression of the nail, or of a porous structure, and when viewed under the microscope has the appearance of a series of vanuously lined pyramids. When moulded, rolled into sheets, or drawn into ropes, it assumes a fibrous character in the direction of its greatest length, in which direction consequently it can be stretched without rupture. If, however, a strip of a sheet be cut off across the fibre, it will be found first a re-entrantity, and then the strip takes place, &c., the direction of the fibrous character is developed in an opposite direction. The elastic properties of gutta-percha were first noticed by Linnæus.

If a piece be subjected to friction, an electric spark can be obtained. On its resistance to heat, it is found that at 53° it becomes soft, at a temperature of 82° to 77° Fahr., gutta-percha has as much tenacity as thick leather, though inelastic and less flexible. In water at 110° Fahr. it becomes less hard, towards 120° Fahr. it becomes doughy, though tough, and at from 145° to 160° it grows soft and pliable, allowing readily of being rolled and moulded. In this state it has all the elasticity of eucalyptus, but this it loses as it cools, gradually becoming hard and rigid again, and retaining any form impressed on it while in this plastic condition.

It is highly inflammable, and burns with a bright flame, disengaging a black smoke like sooting wax. The specific gravity of gutta-percha has been variously stated, from 0.9928 to 0.9993. It is insoluble in water, alcohol, dilute acids, and alkalis, but dissolves in an oil of turpentine, fusible oil of carbon, cold oil, eucalyptus oil, or of eucalyptus, and its own oil,—for it yields by destructive distillation in oil similar to that yielded by eucalyptus, under the same treatment. It is not acted on by the essential oils, neither is it praty, and it is softened by hot water, absorbing a small quantity of the water, which is slowly prated with in cooling.

Manufacture and Applications.—Gutta-percha, as received in England, is in irregular lumps, and is frequently adulterated with mineral stones, sand, bark, sugar, and other foreign matters, and the first step in its manufacture is to cleanse it thoroughly. The blocks are first sliced by means of a powerful machine, which driven by machinery, and provided with a set of three strong chisel like knives, by which it is divided into thin sheets. These are placed in wooden troughs filled with water, and loaded by means of a screw, the gutta-percha being as soft as butter, is taken out in baskets and placed in a wooden trough, called a "divelling" machine, which leads it into fragments, the soft fall into a trough of water, and the impurities sink to the bottom, leaving the pure gutta-percha floating on the surface. This mass is then taken out by means of perforated shovels, thoroughly washed in cold water, and dried in baskets. It is then packed in rackets into chests heated by steam, and left till it be quite soft, when it is at once removed, and kneaded or masticated by means of a cast iron cylinder, with a movable and an internal revolving toothed iron ring,—the result being a homogeneous dough like rubber, or a mass. Sometimes various substances are introduced into this machine, which is called a "masticator," to increase the hardness or density of the gutta, or to colour it,—such as orange or red lead, chrome, vermilion, yellow ochre, sulphur, eucalyptus, gypsum, or tann, one being taken to use such substances only as are necessary to the purpose of the operation. The mastication is conducted with great nicety, as at the will of the operator it is soft and elastic or hard and heavy substance can be produced. When sufficiently masticated, the gutta is placed whilst still hot between two thin cylinders, and thoroughly rolled. By means of an endless band of felt the gutta is returned again to the cylinders, the distance between which is gradually diminished so as to compress and completely drive out any contained air from the gutta-percha. These are various machines for cutting diving boots, &c., to a uniform width, and for rounding off the edges and finishing sulcus for boots are made by cutting a long strip of the required width, and then passing the strip under a hollow die.

In making piping a machine is used consisting of a cylinder, with a die piece attached of the requisite size. By means of a piston the gutta-percha, which is introduced into the cylinder in a plastic condition, is driven through the die piece, and the piston gives the exact diameter of the pipe. The machine is driven by a steam engine, it passes immediately into a trough of water, which "sets" it, and prevents it from collapsing. The value of gutta-percha piping is very great, it does not contaminate water as lead piping does, it withstands acids, damp, &c., and is easily repaired, being shortened, lengthened, or repaired without trouble or expense, and its acoustic properties have led to its employment largely in the manufacture of anal, stethoscopes, and other instruments. Gutta-percha speaks of a new use to be seen in nearly every office.

The substance too, from the fact that few acids and alkalis affect it, especially if dilute, is largely employed for funnels, siphons, and other chemical apparatus.

In telegraphy gutta-percha is of the very highest importance, being a cheap, lasting, and perfect insulator, easily applied to telegraphic wires. The general method of coating telegraph wire is by changing a cylinder with plastic gutta-percha, and forcing it through a die-piece, the wire forming a central core. As the wire

is drawn through this "die" or "moulding" piece, it becomes coated to the requisite thickness, and after passing through water it is wound on drums ready to be coated with tinned copper, and with galvanised iron wire for telegraphic submarine cables.

This substance, with a hard gutta-percha, which in its plastic condition, receives an impression, which it retains when solid, employed in its employment in the decorative and fine arts, where it is used to dress the lines, &c., in the making of moulds from electrotypes. See *Journal of Arts*, 1887.

In the production of imitations of silk and other ornamental woods, gutta-percha has been largely used, since by the admixture of various substances, such as "graining" or "mimbling" can to very nearly imitate natural, and a coating of a solution of gutta-percha gives a finish of great brilliancy.

Substitutes.—Many substances have been recommended as substitutes for, or as supplementary to, gutta-percha. Amongst these Butta gum undoubtedly holds the first place. It is obtained from the *Hemiphus Balata* (Dutch), a tree found in British and French Guiana, Java, &c. Prof. Bleeker seems to have been the first to direct attention to the substance, by bringing it before the notice of the "Société de Arts" in 1867. The Butta gum combines in some degree the elasticity of eucalyptus with the ductility of gutta-percha, being easily softened and becoming plastic, and being easily moulded like gutta-percha. Whilst small pencils have been sent to the Highland have met with a ready sale, and were remarkably strong and free from adulteration. But unfortunately, through the difficulty of collection, the occupation being dangerous and unhealthy, the supply of this excellent article was soon fallen off, and increased by making incisions in the bark of the tree about 7 feet from the ground, a ring of clay being placed around to catch the milk as it exudes. A large tree is said to yield as much as 45 lb. of "day gum," the product of the tree is called *Chrysophyllum*, Colling (*Diospyros elliptica*, Dill.), is a most interesting substance, and may yet prove in article of commerce if properly treated, at present, although by heat it becomes plastic and ductile, it is not so easily worked as gutta-percha. The tree found very generally distributed in Weyang, Congo, Transvaal, &c.

Many of the euphorbia yield milky juices which have some at least of the properties of gutta-percha. The chief amongst these are the *Euphorbia corollata* (*Euphorbia corollata*, Linn.), and the Indian spurge tree (*E. tiruwalli*, Linn.) of India, and some euphorbia at the Cape of Good Hope. The *Alstonia* or palm gum (*Alstonia scholaris*, Linn.) of the Indian mind (*Alstonia scholaris*, Linn.), have also been recommended as substitutes for gutta-percha. But attempts made to utilize these substances have as yet been unsuccessful.

Native Supplies.—A very important matter for consideration is the question of the future supplies of gutta-percha. It is after all only a spontaneous natural product. If a Malay or Chinese wishes to plant pepper, gambier, &c., he burns down a portion of the forest, and when he has raised two or three crops he clears a new portion, and thus finally wooded spots become denuded of trees, and covered with rank grass rendering them unfit for further cultivation. Again, to obtain the gutta-percha the trees are cut down, and none are planted in their stead, so that in districts where they were in abundance only a poor and scanty growth remains. It is not a wonder indeed that a single tree is left. A writer in the *Sarawak Gazette* says that from 1851 to 1875 over 90,000 pencils (of 193 lb. each) of gutta-percha were exported from Sarawak alone, and this must be at least 3,600,000 lb. of gutta-percha. At the same time that practices the tree at all is that it is now cut and used till it is 25 to 30 years old. Soon or later recourse must be had to cultivation and cultivation.

GUTZKOW. KARL (1811–1878), one of the most distinguished of modern German novelists and dramatists, was born 17th March 1811 at Berlin, where his father held a clerkship in the war office. After completing his education at the Friedrichswerder gymnasium, he entered upon the study of theology and philosophy at the university of his native town, where, having had his interest awakened by the political and social questions of the time by the Paris revolution of July 1830, he, while still a student, began his chequered literary career by the publication in 1831 of a periodical entitled *Fon und Journalisten*. Although, as was to be expected, the serial was a failure and was soon discontinued, it procured for him the notice of Wolfgang Menzel, who invited him to Stuttgart, and assumed the editorship of the *Intelligenzblatt*. At the same time he continued his university studies, first at Jena, then at Heidelberg, and latterly at Munich. In 1833 he published anonymously at Hamburg *Dreissig Jahre Narren an eine*

¹ *Journal des Arts*, Oct. 8, 1867, also Aug. 24, 1860, and March 4, 1864.

² *Transvaal Chronicle*, Sept. 2, 1878.

Niemann, and in 1833 appeared at Stuttgart *Maha Gien, Geschichte eines Gottes*, a fantastic and satirical romance intended to ridicule the current conceptions of the divine. In 1835, on account of a difference with Menzel, he discontinued his contributions to the *Literaturblatt*, and went to Frankfurt, where he became collaborator with Dülfer on the *Pharos*, and also founded the *Deutsche Revue*. In the same year appeared *Wally, die Zwieslerin*, from the publication of which may be said to date the school of writers who, from their opposition not only to Romanticism but to all the time honoured literary, social, and religious traditions, have received the name of "Young Germany." The work was directed especially against the institution of marriage and the belief in revelation, and whatever attention it might have attracted from its own merits was tenfold increased by the action of the Government, which, besides condemning its author to three months' imprisonment, decreed the suppression of all he had written or might yet write, and it prohibited him from exercising the functions of editor within the states of the *Brund*. During his term of imprisonment Gutzkow employed himself in the composition of his treatise *Zur philosophie der Geschichte*, published at Hamburg in 1836, in which he opposed the Hegelian theory as to the nature and ends of history. On obtaining his freedom he went to Frankfurt, where, shortly afterwards, he was married, and where he wrote several volumes on various subjects which he published at Hamburg and Stuttgart, but finding himself hampered in his literary undertakings by the prohibitions of the Prussian Government, he removed in 1837 to Hamburg. Here he inaugurated a new epoch of his literary activity by bringing out his tragedy *Michaelis Savage*, which immediately made the round of all the German theatres, and first decidedly won the ear of Germany for the modern drama. Of his numerous other plays the majority are now neglected, but a few have obtained an established place in the repertory of the German theatre, especially the comedies *Joys and Shrews* (1844) and *Das Verbild des Teufels* (1847), and the tragically *Uziel Acaata* (1847), the deep tragic interest, fine dramatic situations, and terse and pregnant diction of the last entitle it to rank among the best dramas of modern times. In 1842 Gutzkow paid a visit to Paris, of which he gave an account in *Briefe aus Paris* (Leipzig, 1842). After his return to Germany he resumed his stay at Frankfurt, where he was chiefly occupied in preparing for the press an edition of his collected works, published in 12 volumes, 1845-46, but in 1847 he went to Dresden, where he succeeded Tieck as director of the court theatre. About the same time began the period of his literary activity to which belongs the series of remarkable works of fiction intended to depict the action and tendency of the principal intellectual, social, and religious forces in modern society. The chief of these novels are *Die Ritter vom Geiste* (9 vols., Leipzig, 1850-52) and *Der Zauberer von Rom* (9 vols., Leipzig, 1859-61). The latter, a study of Roman Catholic life in southern Germany, is generally regarded as his masterpiece, and its vigorous and trenchant delineations of character are not more notable than its keen analysis of the motives, underlying religious professions, and its subtle penetration into the characteristics and tendencies of the various forms of religious opinion. In regard, however, to both works, it may be objected that their great length, their somewhat tedious dillying over unimportant details, the intricate nature of their plots, and the hampering influence of their controversial purpose lessen considerably the legitimate effect of their many striking and original character portraits, their skillfully arranged dialogues and frequently powerfully dramatic scenes, and the cunning manner in which their incidents are blended into one whole. The success of *Die Ritter vom Geiste* suggested to Gutzkow the establishment

of a journal on the model of Dickens's *Household Words*, entitled *Unterhaltungen am häuslichen Herd*, which first appeared in 1852, and was continued till 1862. In 1864 he had an attack of insanity, during which he made an attempt upon his life, and although after his recovery he continued to write as voluminously as formerly, his productions show lamentable decided traces of failing powers. To this period belong the historical novels *Hohenstaufenruin* (5 vols. 1868) and *Krös Eiliedt* (3 vols. 1872), *Lebenbilder* (3 vols. 1870-73), consisting of autobiographic sketches, and *Die Söhne der Dämonen* (3 vols. 1870), the plot of which is founded on the story of Karpur Hauser. On account of a relapse of his nervous malady, Gutzkow in 1873 made a journey to Italy, and on his return took up his residence in the country near Heidelberg. Although some time before his death he had been confined to his sick chamber at Frankfurt, its occurrence, 16th December 1878, was due to accidental suffocation from smoke.

The writings of Gutzkow suffer in character from the controversy which embittered his life. His didactic purpose was too strong to allow his fine artistic faculty full freedom of action, and notwithstanding his time dramatic might, firm grasp of character, rich vein of original thought, and wonderful comprehension of the principles at work in modern society, he did not possess that command of his means which was necessary to mould them into poetic completeness. But although his popularity has not been commensurate even with his merits, no recent writer has exerted a more powerful influence on the opinions of modern Germany, and if his works are not destined to live by virtue of their inherent value, many of them will always be of interest as the mirror in which the intellectual and social struggles of his time are best reflected.

An edition of Gutzkow's collected works appeared at Jena, 1878-79. Since his death the name of a popular edition has been undertaken, the first volume of which, containing the autobiography of his boyhood and his miscellaneous poems, has already appeared. *Die Rückblicke auf mein Leben*, published in 1876, deals specially with that period of his life, which he was director of the Dresden theatre. A complete biography by Johannes Freche is now in the press of preparation.

GUTZLAFF, KARL FRIEDRICH AUGUST (1803-1851), a missionary to China, was born at Pyritz in Pomerania, 8th July 1803. At an early age he cherished a strong desire to become a foreign missionary, but the poverty of his parents made it impossible for them to aid him in attaining his wishes, and he became apprentice to a saddler in Stettin. In 1821, however, he made known his inclination to the king of Prussia, through whom he obtained admission to the Kadetgymnasium at Halle, and afterwards to the mission institute of Jankin in Berlin. In 1826, under the auspices of the Netherlands Missionary Society, he went to Batavia, where by intercourse with the Chinese residents he perfected himself in the Chinese language. He, however, severed his connexion with the Netherlands Society in 1828, and went to Singapore, and in August of the same year he removed to Bangkok, the capital of Siam, where he occupied himself with translating the Bible into Siamese. In 1829 he married an English lady, who aided him in the preparation of a dictionary of Coolin China, but she died in August 1831 before its completion. Shortly after her death he sailed to Mazao in China, where, and subsequently at Hong Kong, he worked at a translation of the Bible into Chinese, published a Chinese monthly magazine, and wrote in Chinese various books on subjects of useful knowledge. He also at different times undertook voyages on the coast of China, and in 1834 he published at London on account of them under the title *Journal of Three Voyages along the Coast of China in 1831, 1832, and 1833*. He was appointed in 1835 joint Chinese secretary to the English commission, and during the opium war and the negotiations

connected with the prices that followed he rendered valuable service by his knowledge of the country and people. On account of the continued refusal of the Chinese authorities to permit foreigners to penetrate into the interior, Gutzlaff in 1844 founded an institute for the training of native missionaries, which was so successful that during the first four years as many as forty-eight Chinese were sent out from it to carry on missionary labours among their fellow countrymen. He died at Hong Kong, August 9, 1851.

Besides the works already mentioned, Gutzlaff is the author of *A Sketch of Chinese History, Ancient and Modern*, London, 1834, and a similar work published in German at Stuttgart in 1847, *China Opusculum*, 1838, and *The Life of Tsao Kiang*, 1851 (German edition published at Leipzig in 1858). A complete collection of his Chinese writings is contained in the library at Munich.

GUY, THOMAS (1644–1724), founder of Guy's Hospital, London, was the son of a lighterman and coal-dealer at Southwark. After serving an apprenticeship of eight years with a bookseller, he in 1668 began business on his own account. He dealt largely in Bibles, which had for many years been poorly and inaccurately printed in England. These he at first imported from Holland, but subsequently obtained from the university of Oxford the privilege of printing. Thus, and by an extremely thrifty mode of life, and more particularly by investment in Government securities, the subscription of these into the South Sea Company, and the subsequent sale of his stock in 1700, he became master of immense fortune. He died unmarried, December 17, 1724. In 1707 he built three wards of St Thomas's Hospital, which institution he otherwise subsequently benefited, and at a cost of £18,793, 16s he erected Guy's Hospital, leaving for its endowment £219,400, he also endowed Christ's Hospital with £400 a year, and in 1705 built almshouses at Tamworth, his mother's birthplace, which was represented by him in parliament. The residue of his estate, which went to distant relatives, amounted to about £80,000.

See *A True Copy of the Last Will and Testament of Thomas Guy, Esq.*, London, 1728; J. Noyththorpe, *A New Hist. of London*, bk. in, chap. i, p. 684, 1778; Nichols, *Literary Anecdotes*, vol. iii, p. 699, 1812; and Charles Knight, *Shadows of the Old Dock-liners*, pp. 8–24, 1865.

GUY OF WARWICK, an old English metrical romance which is known to have existed in French as early as the end of the 13th century. Its authorship has been assigned to Walter of Bæter, a Franciscan monk of the 13th century, and, although this supposition has been generally disputed, Tanner regards it as probable. The romance has been retouched by some French or Anglo-Norman minstrel, but is evidently of Saxon origin, and is allied to the story of Guido Tynius in the *Gesta Romanorum*, and probably to the romance *Sir Guy*, quoted by Chaucer in his *Rime of Sir Topas*. The hero of the story is Sir Guy of Warwick, who is said to have been the son of Siward, baron of Wallingford, to have married Pelicia, the only daughter of Roland, a famous Saxon warrior, to have become earl of Warwick in his wife's right, and after conquering Colbrand the Dane to have lived as a hermit till his death in 939. The earliest English chronicler who mentions the story is historical is John Harding. Tanner is of opinion that the first form of the romance dates from the battle of Brunanburgh, the "Vinheula" of the *Eglogica*, but though the story has some basis in tradition, the chief events of the hero's life are plainly mythical. Although the romance had once great popularity, it now appears dull and tedious, and has no other than an antiquarian interest.

An edition of the romance in French prose appeared at Paris in 1685 printed by Antoine Courcier, and is also referred to in the *Old French Romance, Terence et Blanche*, written about 1480. The earliest English edition is that without date printed at London by William Copland, who died in 1668 or 1669. There exists also an edition printed at London by John Cawood, without date, another by Samuel Rowlands in 1667, and three by O. Bates in 1700. The

earliest English manuscript of the romance is that contained in the Auchinleck MS in the Advocates' Library, Edinburgh, which is, however, imperfect at the commencement and in the middle. It was printed in the Abbotsford Club in 1840. There is a perfect copy in the library of Gair College, Cambridge, and another in the Cambridge University Library. A fragment of the romance, from a MS in the British Museum, was privately printed by Sir Thomas Phillips, 1838, and the same fragment was reprinted in the Abbotsford edition. The manuscript in the University Library, Cambridge, was printed for the first time in the *Romance of Guy of Warwick*, edited for the early English Text Society by Zupitza, 1875. All the other versions appear to have been translated from the Anglo-French version. There is, according to Zupitza, at least eight French MSS in existence,—three in London, one at Oxford, two at Cambridge, one at Cheltenham, and one at Worcester. There is also a copy in the Imperial Library of Paris, and there was one at Bingen in 1487, and one at Brussels in 1487. A portion of the *Wolffenbüttel* MS has been edited by G. A. Heiberg in the *Programm der grossen Stadtschule zu Pommern als Einleitung zur Michaelisfeier*, 1872. See also Zupitza, *Die Literarische Geschichte von Guy von Warwick*, 1818; *The Photo MS*, edited by Hilos and Furnival, vol. ii, and A. Tannu, *Die Sagen von Guy von Warwick*, 1877.

GUYON, or GUYON, JEANNE MARIE BOUTVIERES DE LA MOTHE (1619–1717), a leading exponent of the quietistic mysticism of the 17th century, was born of wealthy and aristocratic parents at Montargis (dep. Loiret), on the 13th of April 1618. From infancy a sickly and evitable child, she was at the age of two years and a half placed for a short time in the charge of the Ursuline nuns of her town, and in 1652 she became resident in the Benedictine convent for a somewhat longer period, but the state of her health rendered it necessary that she should again be taken home, where for a time she was left almost exclusively to the care of domestics. From her seventh to her tenth year she was once more with the Ursulines, and after another short interval at home she next passed eight months in the Dominican cloister, where she spent much time in reading the Bible, and in committing large portions of it to memory. In her 12th year she communicated for the first time, and also began to form some acquaintance with the writings of St. Francis de Sales and of his disciple Madame de Chantal, "la Sainte de Monthelon." In imitation of the latter, she tells us in her autobiography that she at this time carried the name of the Saviour visibly inscribed on her person, subjected herself to severe bodily austerities, and made a solemn vow ever to aim at the highest perfection in an absolute surrender of her will to God. She earnestly wished also to take the veil, and in fact made an attempt, by means of a forged letter purporting to be signed by her mother, to gain admission into the order of the Visitation of Mary, but her father interfered. In 1663 she removed along with her parents to Paris, and went much into society, where her youth, beauty, and talent secured for her a very flattering reception, in the following year, before she was quite sixteen, she was married to M. Guyon, a man of some wealth and position, but of weak health, and twenty-two years her senior. The union, on her side at least, had not been dictated by love, her husband's affection, though probably genuine enough, appears to have been of a somewhat tepid kind, and disparity of age, as well as wide differences of taste and habit between herself and M. Guyon, combined with other circumstances, such as the jealousy of her mother-in-law, and her own eager temper, to make her married life anything but happy. She "began to eat the bread of sorrow and to mingle her drink with tears," and her lonely and desolate heart was not comforted until it found quiet in God. It was in her twenty-first year, on the 22d of July 1668, she tells us, that, after much restless tossing, she was seized with the ague, and, after some religious writers, much spiritual conversation with those who knew best about the mysteries of the "inner life" and the happiness of the state of "recollection in God," much groping in deep darkness, and much wrestling in agonized

prayer, she at last experienced the change of heart which filled her with joy and peace in the life of faith. The words in which she describes that crisis, it indeed they are not coloured by later experiences, are interesting and important, as showing that thus early she had already reached all that was distinctive of her quietism. "Nothing was more easy to me now than to practise prayer. Hours passed away like moments, while I could hardly do any thing else but pray. The fervency of my love allowed me no intermission. It was a prayer of rejoicing and of possession, wherein the taste of God was so great, so pure, unblended, and uninterrupted, that it drew me above the powers of the soul into a profound recollection, a state of confiding and affectionate rest in God, existing without intellectual effort. For I had now no sight but of Jesus Christ alone. All else was excluded in order to love with greater purity and energy, without any motives or reasons for loving which were of a selfish nature." In the months and years that followed she learned by much experience how difficult it is to keep even such heights as the soul has already gained, but her aim, ever more clearly seen and more steadily followed, continued to be "entire consecration," "perfect faith and love." Amongst those who were helpful to her during this period was Geneviève Granger, the pioneer of a Benedictine community in Paris, under whose influence she, on July 23 (St. Mary Magdalene's day), 1872, drew up a solemn act of consecration sealed with her ring and signed with her blood, in which she surrendered herself to Christ as His spouse, accepting as a part of her marriage portion "the temptations and sorrows, the crosses and the contempt, which fell to Him." In the beginning of 1874 she passed into a state of "privation" or "desolation," which she considers to have continued with but slight variations for somewhat more than six years, during the whole of this period, however, she had the benefit of the spiritual direction of Deiot, a kindred spirit, whose mystical writings she afterwards edited. On the 21st of July 1876 she was left a widow, with three surviving children,—two sons and an infant daughter,—and began to live a life of still deeper seclusion and isolation than before, interesting herself, however, in works of charity, and in the education of her family, in connexion with the latter occupation she commenced and made some progress in the study of Latin. Her temptations and crosses continued nevertheless to multiply, she began to lose hope, and to regard herself as wholly forsaken by God, in her deep despondency she began to correspond with Francis de la Combe, superior of the Bernabites at Thonon, Savoy, with whom she had ten years before become acquainted, and in whom she had even then recognised a sympathizing spirit. On the 22d of July 1880 she tells us her soul was delivered from all its pains. "From the time of the first letter from Father La Combe, I began to receive a new life. I was then, indeed, only like a dead person raised up, who is in the beginning of his restoration, and is raised up to a life of hope rather than of actual possession, but on this day I was restored, as it were, to perfect life and set wholly at liberty. I was no longer depressed, no longer borne down under the burden of sorrow. I had thought God lost, and lost for ever, but I found Him again. And He returned to me with unspeakable magnificence and purity. In a wonderful manner, difficult to explain, all that which had been taken from me was not only restored, but restored with increase and with new advantages." In this changed state of feeling she began to revolve new plans for the disposal of the remainder of her earthly life. She for some time thought of winding up her worldly affairs and taking the veil, but her duty towards her children, especially the two younger, seemed to prohibit that step. Several proposals of marriage were also received, but re-

jected. Gradually, in the course of 1881, she had almost, though with hesitation, reached the conclusion that she was called to active religious work, and the field to which inward intimations seemed to point was that part of France and Savoy which borders on Geneva, if not Geneva itself. The advice of D'Aranthion, titular bishop of Geneva, was asked and obtained, he approved of the proposal. After making some important arrangements with regard to her property, and entrusting her two sons to the care of suitable guardians, she accordingly secretly left Paris accompanied only by three female attendants and her daughter, then a child of five years of age. The party arrived at Arancy on the 21st of July, on the following day, at the tomb of St. Francis de Sales, Madame Guyon renewed her spiritual marriage with the Redemptor, and finally she fixed her abode at Gex under the spiritual care of D'Aranthion, by whom La Combe was assigned to her as her director in the place of Bartol, who had died some time before. Here she at once began her benevolent labours, tending the sick and poor, praying with them and giving them religious instruction, yet still it seemed to her as if the "goal of her mission was not yet broken." Something within her whispered that she had not yet found the great and special work to which God had been calling her. Amongst other things the state of her director caused her much solicitude. She saw that he had much, but felt that he ought to have more. His vocation at last was revealed to her, to become to him a spiritual mother, and her efforts towards the fulfilment of that vocation were not in vain. La Combe at last became possessed with the doctrine of present sanctification by faith in the Saviour, and began to preach accordingly. Opposition and persecution almost immediately began, Bishop D'Aranthion did not fail to take notice of the new doctrine, though on this occasion it escaped formal condemnation by the authorities at Rome, seeing, however, that Madame Guyon was the real author of the heresy, if heresy it was (and it certainly seemed to involve a theory of perfectionism hardly compatible with Catholicism), he resolved that she should not continue her activities within his diocese unless she should consent to accept a sphere where the facilities for doctrinal propagandism would be less than those for the exercise of ordinary benevolence. He accordingly proposed that she should give what property still remained within her control to a religious house at Gex, and that she should herself become prioress, this proposal, however, she declined, chiefly on the general ground that it did not seem to be in accordance with the designs of God in regard to her. The alienation of the bishop now made her stay at Gex to be far from comfortable, and accordingly, at the close of a residence of rather more than six months, she removed early in 1882 to Thonon, apparently in the expectation of being near her adviser La Combe. Here she remained for upwards of two years, engaged in religious work of various kinds, especially in spiritual conversation with the people of the neighbourhood, and in tending a small hospital which, at the suggestion of her director and with the assistance of some benevolent ladies of Thonon, she had formed. Meanwhile her doctrines of "pure love" and of that "fixed state" which consists in the complete identification of the human will with the will of God were taking more definite shape, and in 1883 they first found literary expression in *Les Trois reus*, probably the best of her writings, and really in some respects a fine performance, which describes the progress of the soul from the commencement of its upward life to its union with God, by a reference to "streams or torrents flowing from the mountain tops with greater or less rapidity and with greater or less docility, and mingling at last in the ocean." Although Madame Guyon was not herself conscious of any disharmony with the teaching and practice of the Catholic Church, her

doctrines could hardly fail to be regarded by the ordinary orthodoxy of that time as more or less hostile to the generally accepted views as to the nature and mode of sanctification, and as to the normal state of the rationally reformed heart, at Thouin they soon gave deep offence, and ultimately it was intimated both to her and to La Combe, on the part of Bishop D'Aruthon, that both must leave the diocese. Her next resting place for a few weeks was Turin, whence, in the autumn of 1684, she removed to Grenoble, where she again became a centre of attraction and influence. Here, for the direction of the many who flocked to her for instruction and advice, she wrote and enlivened her *Moyen court et très facile de faire sa prière*, a treatise in which she pointed out, doubtless in a manner highly susceptible of misconstruction, that prayer might often well be both silent and wordless. The commencement of her commentaries on the Bible also dates from this stay in Grenoble. Her numerous and popular "conférences" or meetings for conversation and prayer or a "self-recollection in God," and the effect produced by the *Moyen court de faire sa prière*, however, speedily excited ecclesiastical opposition similar to that which she had already encountered at Gex, and although the bishop (Camus) was himself disposed to be tolerant, if not friendly, she was ultimately constrained, in the spring of 1686, to yield to strong representations, and seek an abode elsewhere. Nice, Genoa, and Vercelli (where she again met La Combe) were visited, but it was finally decided, with the advice and consent of her friends, that Paris now offered itself as the field of labour most suited to her powers. Here accordingly she arrived on the 22d of July 1686, and soon she and her teaching began to meet with a very favourable reception in the higher circles of society. But meanwhile the doctrine of Molinos and the *Quête Spirituelle* had been formally condemned by the Inquisition at Rome, and the sentence had been taken up as a signal, especially in France, for the persecution of all suspected quietists. In October 1687 La Combe was suddenly arrested by a royal "lettre de cachet" and committed to the Bastille, and by the same authority Madame Guyon herself was, three months later (29th January 1688), ordered to be detained as a prisoner in the convent of St Marie in the Faubourg Saint Antoine. The charges brought against her were the maintenance of heretical opinions, the holding of private religious assemblies, contrary to the practice and rules of the Catholic Church, for the spread of these opinions, the publication of a dangerous book containing opinions similar to those of the *Spiritual Guide* of Molinos, and correspondence with Molinos. These, however, were not destined to come to a definite issue, for through influence which friends succeeded in bringing to bear upon Madame de Maintenon a release was obtained in the following October. Madame Guyon now went to live for the most part with her daughter, who had become the Comtesse de Vaur, at the family seat in the neighbourhood of Paris, but while on a visit with the duchess of Choiseul she became acquainted with Fénelon, and a considerable correspondence began. Her influence continuing to make itself felt at Paris, Dijon, Versailles, and other places, especially in the institution of St Oyr, founded by Madame de Maintenon in 1686, the attention of theologians was drawn afresh to the "new spirituality," as it was called, and among others both the Port-Royalist Nicole and Bossuet, bishop of Meaux, sought personal interviews. The latter, to whom she had submitted not only all her printed works but also the manuscript of an autobiography which she had written while in confinement in 1685, after more than one long conference, is understood to have expressed himself as on the whole satisfied of her orthodoxy, but the publication by Nicole of the *Béatitude des principales Écrivains des Quatre siècles* appears to have had an exciting influence on the

public mind, a rumour, prejudicial not only to the orthodoxy of Madame Guyon's faith, but also to the purity of her life, were industriously spread, and caused great scandal in the highest quarters, so that at last she was constrained to write to Madame de Maintenon requesting that a number of suitable persons might be selected for the purpose of judging both of her doctrines and her morals, and offering at the same time to submit to any degree of confinement and restraint until it should please the king to appoint such persons. A commission was duly nominated, consisting of Bossuet, Bishop (afterwards Cardinal) De Noailles, and Trousson, the superior of St Sulpice. To this tribunal she then requested submitted the *Moyen Court*, *Les Torrens*, and the manuscripts of her commentaries along with her autobiography, to which she added her *Justification*. The outcome of many deliberations, extending over some months, was the preparation of twenty-four articles, usually called the "Articles of Issy," relating to the doctrine of "pure love." Her refusal to sign a "condemnation of religious errors," as drawn up and presented to her by Bossuet in a pastoral ordinance and letter, now led to an open rupture which resulted in her imprisonment, on this occasion at Vincennes, on the 27th of December 1695. Bossuet now set himself to prepare his *Instruction sur les États d'Oraison*, which he submitted before publication to De Noailles, and amongst others, to Fénelon for approval. The latter after reading the manuscript, with his usual imprudence, not on account of its doctrine (with which he did not disagree), but on account of its personalities, which he held to be unequalled for and unjust. Almost forced thus into the position of a champion of Madame Guyon, he published in 1697 his *Maximes des Saints*, a statement of the leading principles laid down by approved writers on the subject of the highest inward experiences and of holy living. In the course of the controversy which followed several important works appeared, which can only be alluded to here, the dispute, as is well known, issued in the formal condemnation of Fénelon (13th March 1699), in which achievement the hostility to Madame Guyon seems to have almost exhausted itself. She was not released, however, until 1702, in which year she was banished to Blois, where the remainder of her life was spent. Numbers of persons of all ranks, and many of them from foreign countries, visited her in this retirement, and both in correspondence and conversation she continued to manifest considerable activity, although feeling herself "called on to glorify God by submission and by private prayer, rather than by active labour." She heard mass daily, received the sacrament every alternate day, and died in full communion with the Roman Catholic Church, after an illness of three months, on the 9th of June 1717.

*La Vie de Madame de la Motte Guyon, des ses penes même, last appeared at Cologne in 1780. It is based upon the autobiography which at the instance of La Combe she is known to have written during her imprisonment in 1688, it afterwards received additions and corrections from her own hands, and was finally entrusted to a confidential friend on the understanding that it should be published until after her death. In addition to *Les Torrens Spirituels*, and the *Moyen court et très facile de faire sa prière*, which was first published in the *Opuscules Spirituels* in 1704, there appeared in her lifetime the *Principes Spirituels* (1689), and *Les Saints, traduits en français, avec des Explications et des Définitions qui regardent la Vie Intérieure* (1715). There are also several volumes of *Lettes aux Chrétiens et Spirituels*, addressed by her to Metznich, Ratisman, and other correspondents, many of them distinguished. The edition of the collected *Œuvres* extends to 40 vols (1787-1791). English and German translations of the various works are numerous. Apart from the *Autobiography*, the only mention of Madame Guyon is yet in evidence in the diffuse but somewhat vague and meagre *Life*, by Thomas O Upland (1854). (J S BE.)*

GUYTON DE MORVEAU, LOUIS BERNARD, BARON (1737-1816), a distinguished French chemist, was born January 4, 1737, at Dijon, in the university of which town his father was professor of civil law. As a boy

at Gyot (Raab), in the middle school of which town he was teaching during the two following years. In 1811 he was again at Pannony, whence in 1812 he was sent to Pesth to study theology. Here he became acquainted with the works of the best German and Hungarian authors, and also took part in the editorship of the *Neu etc* (National) *Plutus*, and in the translation of Hubner's *Lexicon*. After about four years' stay at Pesth, he obtained the degree of doctor of divinity, and returned to Pannony, where he devoted himself to dogmatic theology and literature. So great was his activity that it is said that there was hardly an Hungarian periodical to which Guzmics was not a contributor. The most important of his theological works are—*A Lath anyas-entregi-nak hablat tamdas* (The doctrinal teaching of the Holy Catholic Church), and *A keresztényeknek viládebeli egyenlőségi* (On Religious Unity among Christians), both published at Pesth in 1823, also a Latin treatise entitled *Theologia Christiana fundamentalis et theologia dogmatica* (Gyot, 1828-29, 4 vols.) Of the other literary labours of Guzmics the most meritorious is a translation of Theophrastus in hexameters published in 1824. His versions of the *Odipus* of Sophocles and of the *Trojan* of Euripides were rewarded by the Hungarian Academy, of which in 1838 he was elected honorary member. From 1832 to the date of his death he was abbot of the *Egyházi Társ* (Ecclesiastical Treasury). In 1832 he was appointed abbot of the wealthy Benedictine house at Bakonybél, a village in the county of Veszprém. While there he built an asylum for 150 children, and founded a school of harmony and singing. He died at Bakonybél on the 1st September 1839.

GWALIOR, a native state in political relationship with the Central India Agency and the Government of India. The state consists of several detached districts, the principal of which is bounded on the N.E. by the Chambal river, dividing it from the British districts of Agra and Etawah, on the E. by Bundelkhand and Sagar (Saugor) districts, on the S. by the states of Bhopal and Dhari, and on the W. by those of Rajgarh, Jhalwar, and Kotah, and on the N.W. by the Chambal, separating it from Karauli (Kerowlee), and Dholpur in Rajputana. The extreme points of the Gwalior territory are in 28° 21' and 26° 52' N. lat., 76° 31' and 79° 21' E. long. The area, including part of the ancient province of Agra and most of Malwa, is 33,119 square miles. The extreme north-eastern part is generally level, bare, and of no great fertility. A little farther south the surface rises into hills. The country is covered with small hills, which stand abruptly out of the level plain. On one of these stands the fortress of Gwalior. The geological formation of these rocky eminences is a very fine-grained sandstone, yielding an excellent building stone. The middle tract is a plateau, having probably an average elevation of about 1500 feet. The Mandu range running east and west forms the southern boundary of the plateau, sloping gently northwards towards it, and dipping precipitously southwards towards the Nerbudda (Nerbudda). The state is watered by numerous rivers. The Nerbudda, flowing west, forms the boundary of the most southern part of the state. The greater part of the drainage is discharged into the Chambal, which forms the north-western and northern and eastern boundary. The Sind, with its tributaries the Kuwari, Asai, Sankh, and other smaller streams, flows through the state. The chief products are opium, known as Malwa opium, wheat, gram, pulses of various kinds, *jodra*, *bajra*, *mung*, maize, rice, linseed and other oil-seeds, garlic, turmeric, ginger, sugarcane, indigo, *aj* yielding a fine red dye, tobacco, and cotton. Many species of wild beasts and birds are found throughout the state. The rivers abound in fish, especially of the carp kind.

Birbhanpur is the site of a considerable manufacture of

fine cottons, silks, and such broadcloths. Iron ore is raised and smelted in many places. The principal imports are British woollens, cottons, silks, cutlery, cashmere shawls, pearls from the Persian Gulf, Ceylon diamonds, and agates from Bundelkhand, gold, silver, manure, copper, lead, and zinc. The chief exports are opium, cotton, tobacco, dyes, and iron. The Indore and Ajmer narrow-gauge railway, now (1879) in course of construction, will pass through the west of Gwalior state, while a railway on the broad gauge, to connect Gwalior town with Agra, is approaching completion.

During the hot and dry seasons the climate is not unhealthy, but during the rainy season fevers prevail, especially in the north. The range of the thermometer is usually small, except during the sultry season, when it sometimes rises to nearly 100° during the day. The average rainfall during the rainy season is 50 inches.

The population of the north-eastern part of this territory is of many elements, comprising, besides Mahabhis (the ruling race), Bundelas, Jats, and Rajputs, with some less distinctly defined divisions of Hindus and Mahometans. There is perhaps no part of India where the tribes of Bakhmans are so various and their number so great as in the southern and south-western parts. The Mahometan population is estimated at about 20 per cent. of the whole. Including the cessions to Sindia under the treaty of 1803, the territories of the Gwalior state were in 1875 estimated to contain a population of about 2,500,000 souls. The total revenue in 1875 was £1,200,000. Education is afforded by 92 schools attended by 3206 pupils.

The Gwalior family, whose aims and chiefs have played so conspicuous a part in the history of India, and whose representative now rules over a state larger than that of Wales, and much richer than many independent kingdoms, was founded by Bhoj Singh, whose father was *patel* (head man) of a Deccan village. Once in the household of the *patel*, Bhoj Singh rose to a high rank, and was soon made head of the community. He was a great warrior. Mahabhis raised through him to Hindustan, he was at the time of his death the acknowledged possessor of lands which still form part of the Gwalior state. His success was due to his son Malad Singh, whose ability as a statesman and a soldier has rarely been surpassed. At his death he was succeeded by his grand nephew Daulat Rao Sindia. The power of Sindia was at this time most dangerous to the British Government, who now began to take measures to break the power of this chief. Sindia entered into a league with the raja of Berar to defeat them, but their allied armies were defeated in 1803 at Assaye by a British force commanded by General Sir Arthur Wellesley, subsequently duke of Wellington. By the end of the same year, the Mahabhis were completely overthrown, and Sindia was compelled to accept peace and to sign a treaty by which he resigned his conquest territories. Eventually, by a treaty concluded in 1806, Sindia's whole force was ceded to Sindia. Daulat Rao died at Gwalior in 1827 without an heir. On his deathbed, he left the state and succession in the hands of the British Government. The succession of a boy of the Sindia family, Mangat Rao, to whom it was thought the widow of Daulat Rao turned, was admitted by the British Government. The young man was subsequently married to the girl daughter of Daulat Rao, and took the name of Feroz Sindia. In 1848 he died without issue. His widow, with the concurrence of the chief nobles, adopted Dignat Rao, a lad eight years of age. The British Government recognised the adoption, and Regent Rao, under the name of Dignat Rao Sindia, succeeded to the present rule (1879). Early in the reign the disturbances took place, and the advance of British troops on Gwalior became necessary to restore order. Two battalions, Malabar and Punjabi, were fought on the day of the 27th December 1848, and the British troops and the mutinous army. They both perished in the total defeat of the Gwalior troops. No event of historical importance has taken place since, except the revolt between the Gwalior contingent and Sindia's army in 1857. The malabar's conduct throughout has been conspicuous for its loyalty. In recognition of his services, the Government conferred upon him the right of adoption, together with lands yielding a revenue of £30,000.

GWALIOR, the capital of Gwalior state, and fortress residence of the Mahabhis Sindia, is situated in 26° 13' N. lat. and 78° 12' E. long., 65 miles S from Agra, and 277 N.W. of Allahabad. Gwalior city has a chief interest—first, as a very ancient seat of Jain worship,

secondly, for its example of palace architecture of the best Hindu period (1656-1716), and thirdly, as the fortress capital of one of the greatest native chiefs of India.

Jain Remains.—There are several remarkable Hindu temples in Gwalior. One, known as the Sas Balu, understood to be of Jain erection, is beautifully adorned with bas-reliefs, and is now ascribed to both by the *Vesuvius* and *Sure* sects. It was finished in 1098 A. D., and, though much dilapidated, still forms a most picturesque fragment. An older Jain temple has been used as a mosque. Another temple in the fortress of Gwalior is called the *Tela Le Mandir*, or "Chakra" temple. This building was originally dedicated to Vishnu, but afterwards converted to the worship of Siva. The most striking part of the Jain remains at Gwalior is a series of caves or rock-cut sculptures, excavated in the rock on all sides, and numbering many a hundred, great and small. Few of them are much more than carvings, though some are cells that may have been originally intended for ascetics. One curious fact regarding them is that, according to inscriptions, they were all excavated within the short period of about thirty-three years, between 1441 and 1474. Some of the figures are of colossal size, and, for instance, is 67 feet high, which is taller than any other in the north of India.

Hindu Palace Architecture.—The palace built by Nis Singh (1686-1716) forms the most interesting example of early Hindu work of its class in India. Another palace of even greater extent was added to this one in 1716, both Jhangri and Sirh Jhangri added palaces to these two—the whole making a group of edifices unequalled for picturesqueness and interest by anything of their class in Central India. Among the apartments in the palace was the celebrated library, and the *Shalimar*, supported on 12 columns, and 40 feet square, with a stone floor, forming one of the most beautiful palace halls in the world. It was, besides, singularly interesting from the experiments to which the Hindu architect was forced to resort to produce the effect of the modern. Of the buildings, however, which so excited the admiration of the emperor Durrani, probably little now remains.

Rock Forts.—The fort of Gwalior stands on an isolated rock. The base of the fort is perpendicular, and when the rock is actually less prominent it has been scalped. Its greatest length from north to south west is a mile and a half, and the greatest breadth 800 yards. The rock attains its maximum height of 343 feet at the northern end, and is everywhere accessible by a steep road, and is further up by huge steps out of the rock, surrounds the fort. The central stands at the north-eastern corner of the enclosure, and presents a very picturesque appearance. The old town of Gwalior, which is of considerable size, but irregularly built, and extremely dirty, lies at the eastern base of the rock. It contains the tomb of Muhammad Ghani, which was erected during the early part of Akbar's reign. The fort of Gwalior, according to Walcott, was built in 773 A.D. by Suyas Sen, the son of the neighbouring country. In 1193 Gwalior was captured by Mahmud Ghori, it then passed into the hands of several chiefs until in 1556 Akbar gained possession of it, and made it a strong prison for captives of war. On the dismemberment of the Delhi empire, Gwalior was seized by the Jats; and of Gwalior. Subsequently it was possessed by Sindhis, from whom it was wrested in 1780 by the forces of the East India Company. A century later it came under the possession of the British government of Gwalior, the adopted son of Dairat Rao Sindhu, who died in 1843 without an heir. A revolution was impending, and the British Government had to interfere. Troops crossed the Ghambur, and unexpectedly found the insurgents were no more. The Maharajah, a few miles distant from the fortress. A battle ensued on the 29th December 1848, resulting in the complete overthrow of the Maharajah. The British contingent stationed in the town was increased, and affairs were placed on a peaceful footing.

GWILLT, JOSEPH (1784-1863), author of the *Encyclopaedia of Architecture*, was the younger son of George Gwilt, architect surveyor to the county of Surrey, and was born at Southwark, January 11, 1784. He was educated at St Paul's school, and after a short course of instruction in his father's office was in 1801 admitted a student of the Royal Academy, where in the same year he gained the silver medal for his drawing of the tower and steeple of St Dunstan-in-the-East. In 1811 he published a *Treatise on the Equilibrium of Arches*, and in 1815 he was elected a fellow of the Society of Antiquaries of London. After a visit to Italy in 1816, he published in 1818 *Notizie Architettoniche Italiane*, or *Complete Notices of the Buildings and Artists of Italy*. In 1825 he published, with notes and valuable additions, an edition of Sir William Chambers's *Treatise on Civil Architecture*, and among his principal other contributions to the literature of his profession are a trans-

lation of the *Architectures of Vitruvius* (1836), a *Treatise on the Rudiments of Architecture, Practical and Theoretical* (1836), and his valuable *Encyclopaedia of Architecture* (1842), which has passed through a great many editions, and was published with additions by Wyatt Papworth in 1867. In recognition of Gwilt's advocacy of the importance to architects of a knowledge of mathematics, he was in 1833 elected a member of the Royal Astronomical Society. In addition to the sciences bearing on his profession he took a special interest in philology and music, and is the author of *Rudiments of the Anglo-Saxon Tongue* (1829), and of the article "Music" in the *Encyclopaedia Metropolitana*. His works as a practical architect are not of much importance, the principal being Markree Castle near Sligo in Ireland, and St Thomas's Church at Charlton in Kent. He succeeded his father as a surveyor of sewers for the county of Surrey, and held that office till 1848. He died September 14, 1863.

GWYNIAD is the name given to a fish of the genus *Corygonus* (*G. lupoides*), inhabiting the large lakes of North Wales and the north of England. At Ullswater it is known by the name of "schelly," at Loch Lomond by that of "powen." It is tolerably abundant in Lako Bal, keeping to the deepest portion of the lake for the greater part of the year, but appearing in shoals near the shores at certain seasons. It is well flavoured, like all the species of *Corygonus*, but is rarely attached to the weight of a pound. The name gwyniad is a Welsh word, and signifies, "shining," and it is singular that a similar fish in British Columbia, also belonging to the family of Salmonids, is called by the natives "gunnat," from the silvery lustre of its scales, the word having in their language the same meaning as the Welsh "gwyniad."

GYARMAT, a Magyar term signifying colony, and applied to several places in Hungary. Of these the following two towns have the largest number of inhabitants.

DEBASSA-GYARMAT, capital of the Cis-Danubian county of Nagrad, is situated on the Ipoly (Eipel), about 40 miles N.N.E. of Budapest, 48° 6' N. lat., 10° 16' E. long. It is the seat of a royal court of law and of the assize, and has Roman Catholic and Lutheran churches, also a Jewish synagogue, a free county hall, a house of correction, a religious institute for girls, and tax, post, and telegraph offices. In 1870 the population was 6435, Magyars and Slavs by nationality.

FÜZES GYARMAT, a market-town in the Trans-Tiszan county of Bekés, is somewhat unfavourably situated in the extensive marshy tract of country known as the Sárköz, 47° 5' N. lat., 21° 13' E. long. The town has few noteworthy buildings, with the exception of the Calvinist church and some elegant private residences. The chief products of the rich, dark, alluvial soil of the neighbourhood are wheat, tobacco, hay, grapes, and other fruits. Housed are cattle, pigs, and sheep (both German and Hungarian) as well as the wide-spreading pasture lands, and numerous water-fowl and wading birds, especially herons, inhabit the reed covered marshes. The water used for drinking purposes is, however, frequently muddy and warm, and unpleasant to the taste. In 1870 the population was 5735, of whom the great majority were Magyars.

GYARMATHA, a market-town in the county of Temes, Hungary, situated in a level but productive agricultural district to the north-east of Temesvár, 45° 50' N. lat., 21° 17' E. long. For some distance round the town the cultivation of wheat, barley, oats, maize, and the vine is largely carried on. Horse-breeding is another source of employment to many of the inhabitants. Gyarmath has few buildings of special interest with the exception of a Roman Catholic church and the ruins of a fort. In 1870 the population amounted to 5125, consisting of Germans, Magyars, and Wallachs.

GYERGYÓ SZENT MIKLÓS, a market-town of Hungary, in the Transylvanian county of Csik, is situated in a mountainous but well wooded district, 96 miles E of Klausenburg, and about 25 W of the Moldavian frontier, 46° 43' N lat., 25° 33' E long. Among the more important buildings are a Roman and a Greek Catholic church, a fine public school, a royal court of justice, and the post and telegraph offices. There are also cattle and timber trading houses, an office of woods, a financial commission agency, and a police station. Cattle and sheep are reared in great numbers in the surrounding country, which is noted also for its cheese, and for the preparation of gun. The number of inhabitants at the commencement of 1870 was 5645, consisting of Magyars, Wallachs, and Magyarized Armenians, the descendants of a band of wanderers who settled here in 1668.

GYGES, founder of the third dynasty, called Meimnad, of Lydian king, reigned about 687–664 B.C. (*v. Gelzer in Rheum Mus.*, xcv). The kindred name Gyges, applied by Homer (*Il.*, ii 664) to the Maconian like, mother of the Moconian leader, supports the statement of ancient historians that he belonged to an old Lydian family. In the reign of Candaules, Gyges, perhaps after banishment, attempted during the troubles caused by the Cimmerian invasions into Asia Minor, to gain the royal power. He was aided by foreign, especially Carian, mercenaries, but was strenuously resisted by the native population. At last it was agreed to settle the decision between the old Heraclid dynasty and the new claimant to the national god Heracles, but, to ensure impartiality, they appealed to him under his Greek form of Apollo. The Delphic oracle gave its answer in favour of Gyges, and the presents with which his gratitude enriched the shrine were soon and described by Herodotus. This story points to familiar and friendly intercourse between Lydia and the Greek states, and that the circumstance impressed itself on the Hellenic mind is shown by many romantic tales current about the fortunes of Gyges (Plato, *Rep.*, ii p 360, Herod., i 8). The contemporary poet Archilochus speaks of the riches of Gyges. Under the Heraclid dynasty Ionian settlements had occupied the whole coast of Lydia, and in friendly relation with the country had rapidly prospered. But the warrior king who now began to rule was not content to leave the sea coast in the undisturbed possession of foreigners. He and his successors maintained almost constant war with the Ionian cities. Gyges captured Magnesia and the lower city of Colophon, but the monarch of the Cimmerians diverted his attention from conquest to the defence of his own capital. At one time he was so hard pressed that he applied to Assyria for help (about 660 B.C.), and paid tribute to Assurbanipal in return for protection against these barbarians. But he afterwards threw off allegiance and assisted Pasmadius, who had revolted in Egypt against the Assyrian rule. It is mentioned in an inscription of Assurbanipal that Gyges was slain in battle by the Cimmerians, and that his son Aidys renewed the tribute.

For a full account of the reign of Gyges, and the ancient authorities for it, see Duncker, *Gesch. d. Alterthums*, vol. ii.

GYLLENBOURG-EHRENSVARD, THOMASINER KRISTINA, BARONNESS (1773–1856), the most eminent female writer of Denmark, was born November 9, 1773, at Copenhagen. Her maiden name was Buntzen. Her great beauty early attracted notice, and before she was seventeen she married the famous political writer Peter Andreas Heiberg. To him she bore in the following year a son, afterwards illustrious as the poet and critic Johan Ludvig Heiberg. In 1800 her husband was exiled and she obtained a divorce, marrying in December 1801 the Swedish Baron Ehrensvard, himself a political fugitive. Her second husband, who

previously adopted the name of Gyllenbourg, died in 1815. In 1812 she followed her son to Kiel, where he was appointed professor, and in 1825 she returned with him to Copenhagen. In 1827 she first appeared as an author by publishing her romance *The Polonius Family* in her son's newspaper *The Lyngby Post*. In 1828 the same journal contained *The Magic Ring*, which was immediately followed by *An Everyday Story*. The success of this anonymous work was so great that the authoress adopted until the end of her career the name of "the Author of *An Everyday Story*." From this time forward she took a foremost place among the writers of her time, but preserved her anonymity with entire success. In 1833–34 she published three volumes of *Old and New Novels*. *New Stories* followed in 1835 and 1836. In 1839 appeared two novels, *Montana the Younger* and *Frederik*, in 1840, *One in All*, in 1841, *Neen and Far*, in 1843, *A Correspondence*, in 1844, *The Cross Ways*, in 1845, *Two Generations*. From 1849 to 1851 the Baroness Ehrensvard-Gyllenbourg was engaged in bringing out a library edition of her collected works in twelve volumes. On the 2d of July 1856 she died in her son's house at Copenhagen. Not until then did the secret of her authorship transpire, for throughout her life she had preserved the closest reticence on the subject even with her nearest friends. The style of Madame Ehrensvard-Gyllenbourg is clear and sparkling, in English reading no closer analogy can be found than between her and Mrs. Gaskell, and *Cygnets* might well have been written by the witty Danish authoress. She introduced into the literature of her country a novel vein of realism and domestic humour, and, although she has had many imitators, she is still without a rival.

GYMNASIUM was the name applied by the Greeks to a building designed for the practice of physical exercises. From the earliest times we hear of athletic sports in honour of heroes and gods. Sometimes they are celebrated among the funeral rites of a deceased chief, sometimes they form part of a periodic festival. At first competitors exercised apart of their outer garments (*gymnasia*), hence arose the name *gymnasium*. Afterwards the habit of exercising naked became universal. In the continuance of their history the Greeks grew more attached to such sports, then free active life, spent to a great extent in the open air, fostered the liking almost into a passion. The victor in any athletic contest, though he gained no money prize, was rewarded with the honour and respect of his fellow-citizens, and a victory in the great religious festivals was counted an honour for the whole state. In these circumstances the training of competitors for the greater games became a public concern, special buildings and officials were provided for the purpose by the state. But, as gymnastics became more and more an institution of social life, the gymnasium was applied to other uses even more important. The most interesting points are the connexion with education on the one hand, with medicine on the other. Due training of the body and maintenance of the health and strength of children were the chief part of earlier education. Except the time devoted to letters and music, the education of boys was conducted in the gymnasium, where their moral training was as carefully attended to by special officers as their physical exercises. As they grew older conversation and social intercourse took the place of the more systematic discipline. Philosophers and sophists assembled to talk and to lecture in the gymnasium, which became places of general resort for the purpose of all less systematic intellectual pursuits, as well as for physical exercises. Plato, whose teaching of education devotes much consideration to gymnastics (see especially *Rep.* iii and various parts of *Leges*). Gymnastic exercises proper were designed, not merely as in Sparta, to foster the taste for war and the activity and strength needed for using weapons, but also to

produce graceful carriage and healthy tone of the body. According to Plato, the sophist Prodicus first pointed out the connection between gymnastics and health. Having found such exercises beneficial to his own weak health, he formulated a method which was adopted generally, and which Hippocrates improved on. Galen, the greatest stress on the proper use of gymnastics, and throughout ancient medical writers, we find that special exercises are prescribed as the cure for special diseases. The regulation of the gymnasium at Athens is attributed by Pausanias (i. 39, 3) to Theseus; Solon made several laws on the subject, but, according to Galen, it was reduced to a system in the time of Clisthenes. Ten gymnasiarchs, one from each tribe, were appointed annually. These performed in rotation the duties of their office, which were to maintain and pay the persons that were training for public contests, to conduct the games at the great Athenian festivals, to exercise general supervision over the morals of the youths (they could, for example, remove any philosopher whose teaching they thought injurious), and to adorn and keep up the gymnasium. This office was one of the ordinary *leitourgia*, and great expense was entailed on the holders. Under them were ten sophronists, with a salary of a drachma per day. Their duty was to watch the conduct of the youths at all times, and especially to be present at all their games. The practical teaching and selection of the suitable exercises for each youth were in the hands of the *paidotribes* and *gymnasts*. The latter also superintended the effect on the constitution of the pupils, and prescribed for them when they were unwell. Alights oiled and rubbed dust on the bodies of the youths, acted as sanguineous, and administered the drugs prescribed.

The gymnasia built to suit these various purposes were large buildings which contained, not merely places for each kind of exercise, but also a stadium, baths, covered porticoes for practice in bad weather, and outer porticoes where the philosophers and men of letters read public lectures and held disputations. In Athens there were three great public gymnasia,—Academy, Lyceum, and Cynosarges,—and every Greek city of consequence seems to have possessed one. Ruins of them exist at Paigum, Ephesus, Alexandria in Thebes, &c., from which, and from the accounts of Vitruvius (v. 11), it would appear that all were constructed on much the same plan. The details will be found most clearly given in Rich's *Dictionary of Greek and Roman Antiquities*.

Much of the healthy buoyant elasticity of mind for which the Greek race is remarkable, as well as the active and beautiful physical development which no other race has ever equalled, is due to the love of gymnastics. The plastic art also owes its perfection in the treatment of the human form to the constant opportunity which artists had of observing the nude body in various attitudes. But abuses were liable to occur. The careful provisions made by Solon and later legislators to keep up the moral character of the gymnasia did not prevent them from fostering the vices which appear so much in Greek life. Though introduced in Rome, where Nero built the first public gymnasium, gymnastics did not suit Italian habits, and never became popular.

Gymnasium, in its modern use, generally signifies a school for gymnastic exercises, but it is sometimes used also to denote a higher school intended to give immediate preparation for the universities. The latter application of the term is especially prevalent in Germany.

GYMNASTICS, in the general acceptance of the term, denotes every exercise which tends to develop and invigorate the bodily powers, such as walking, running, riding, fencing, rowing, skating, dancing, and many others. In another sense gymnastics includes those manly and healthful games which have been encouraged by all high-minded nations

as calculated to improve the physical strength and keep alive the martial spirit of their people. In a more limited sense, the term has been employed to denote the modern system of bodily exercises. Physical strength was the valuable good of antiquity, and we therefore find the elements of a system of gymnastics in most nations from the earliest times. In the infancy of society, when the individual was valued according to his personal strength and prowess, it was only natural that the utmost care should be bestowed on those arts which most surely led to distinction. All education then consisted chiefly in the practice of such exercises as were best calculated to develop muscular strength and make the tenure of life as secure as possible. The first gymnastic exercises, both of those nations that reached the highest civilization and of barbarians, were the same, viz., running, leaping, swimming, and the throwing of missiles. These exercises were at a very remote period systematized and reduced to a science by the Greeks (see GYMNASTIKUM). Among the Romans of the republic, the games in the Campus Martius, the duties of camp life, and the preliminary military exercises to which the soldier devoted himself, besides the enforced marches which were imposed upon him, and the part he took in the execution of public edicts, saved to take the place of the gymnastic exercises as established by the Greeks. In the Middle Ages, chivalry with its jousts, its feats of horsemanship, and encouragement to the arts of fencing, single stick, &c., took the place of the ancient gymnastic exercises. The invention of gunpowder, which modified the system of warfare, and the increasing value of individual life,—in a word, the progress of civilization—closed the career of the champions and votaries of physical strength, and gymnastic exercises in the course of time were neglected. Mousseaux, in his *Émile*, was the first to call attention to the injurious consequences of such indifference, and it is in a large measure to his eloquent appeal that gymnastics have in recent times been held to constitute an integral part of school education, although it cannot be said that in every country the practical application of his views has met with much success. The good effects of the innovation which he advocated have nowhere been more strikingly exemplified than in Germany. When many parts of that country groaned under the iron yoke of Napoleon, Jahn and his followers, encouraged by the Prussian minister Stein, were establishing *Turnplätze* or gymnastic schools, from which issued the well-trained youth who in due time drove the French legions across the Rhine. Of late years public attention has been drawn to the increasing deterioration in the physique of the population of England, and several proposals have been put forward to check an evil which can no longer be concealed. These proposals may be arranged under the banners of two rival camps. One maintains the opinion put forward in a work just published on exercise and training, in the following words (*Exercise and Training*, 1878) —

"In our opinion the natural virtues of exercise of cricket, football, and rowing for boys, hunting, shooting, &c. for men, pursued at the different seasons of the year, are quite sufficient for a proper development of all parts of the body, in accordance with the uses of the different limbs, for the development of special muscles, or, where a great variety of exercise cannot be procured, a system of gymnastics may be pursued. To the advocates for the adoption of systematic physical education by means of gymnasia at our schools, we must concede the immense value of such establishments in our large towns, where outdoor exercise and field sports are difficult of attainment, or in cases where from the physical debility the muscles have to be gradually developed, still we maintain that the national games played by the English schoolboy are infinitely superior to any system of artificial exercise ever devised."

On the other side we have the advocates of physical education by means of regular gymnastic exercises superintended by trained and educated teachers, the whole placed

under competent medical supervision. Among the staunch supporters of the latter view may be named Dr Roth, and Mr's Wesslake, a member of the London School Board. The following considerations appear to be of great weight as supporting the views put forward by the advocates of physical education. While the national games may seem to some sufficient for the physical development of the ordinary youth and manhood of a country, it must not be forgotten that there is a vast and rapidly increasing portion of the population, especially in large cities, to whom the "national games" are quite unknown diversions, and that it is among this class that the most marked deterioration in physical development is only too apparent. The children of this class dwell crowded up in narrow, ill-lighted, and worse-ventilated courts, from which they are often dragged to undergo a certain amount of mental training, in many cases perhaps too severe to be sustained by their debilitated and enfeebled bodies. Whilst so much is being done for the mental culture of the rising generation, then physical culture is left very much to inclination or chance. But there is another source of danger put forward by those who advocate the sufficiency of the national games, viz., "the neglect of any classification of games at school, and allowing the weak and strong to engage in them indiscriminately, to the detriment of the physical wellbeing of the more delicate," and they proceed to show the injury that may be done by the present system of competitive outdoor sports, unregulated by judicious restraint. Important information on this subject will be found in two papers published in the *St George's Hospital Reports* for 1874-76, by Mr C Roberts, F.R.C.S., and by Mr Stueet, and another in the *Tenth Annual Report of the State Board of Health of Massachusetts*, by Professor Edward Hitchcock. Mr Roberts points out that between the ages of fifteen and seventeen the greatest amount of physical development takes place, and that if at this period a boy is subjected to a great strain upon his strength his future growth may be interfered with, or the foundation laid of constitutional disease. Prof Hitchcock's paper embodies the experience of seventeen years of careful observation. Acting upon the well-grounded opinion that neither mental acuity nor mental development can exist upon an unhealthy animal organization, and admonished by "the sad deaths of two promising young men, and the breaking down in health of others just at the end of their college courses," the authorities of Amherst College were impelled to demand that the college officials should give a proper attention to physical health as well as to the culture of these powers for which departments were ordinarily created endowments made. In 1859 a department of physical education and hygiene was created, concerning which we read in the catalogue of 1861-62 that—

"Its design is to secure habitual daily exercise and recreation to all students, to instruct them in the use of the vocal organs, movements of the body, and manner, as connected with oratory, and to teach them, both theoretically and practically, the laws of health. This daily physical training is a part of the regular college course. The professor is an educated physician, and has not only a general oversight of the health of the college, but students have the privilege of consulting him without charge. While the gymnasium will furnish opportunities for the highest physical training, the required exercises will be such as can be performed without undue effort or risk of injury."

Each class, at a stated hour on four days of the week appears at the gymnasium, and all perform their part in systematic and methodical exercises timed to music. The statistics of this department show some interesting facts in reference to the duration of sickness among students. While the average amount of time lost on account of sickness by each labourer in Europe is found to be 19 or 20 days each year, the returns of Amherst College sick-list for term time give 2.64 days as an annual average of time lost to every student, and 11.36 days to each sick student for

17 years. A decrease in the amount of sickness during the course is also an important feature in the health of the college.

From replies to questions put by Dr Roth to the heads of the educational bodies, and also from the recorded personal experience of his son, Mr B Roth, F.R.C.S., it appears that considerable attention is now being paid to the best methods for improving the physical education of the people in nearly all the Continental states. The greatest activity is perhaps shown by Sweden, Germany, France, Belgium, and Italy, and even in Russia the question is attracting much public attention, Dr Begkind having been ordered to write a special book on the subject. In Hungary also the Government has made physical education an obligatory part of the school curriculum. In Prussia gymnastic instruction was formally recognized by a cabinet order of June 1812, and by a royal order of 1862 a guide-book of gymnastic instruction was introduced into the primary schools and into the training colleges for teachers. In Sweden this subject appears to have earlier attracted attention, for in 1813 the Government, under the direction of P H Ling, founded the Royal Central Gymnastic Institute at Stockholm, where teachers of both sexes are gratuitously trained for two years, and receive a diploma after undergoing a theoretical and practical examination. In Belgium, under the united efforts of MM Delcour and Lemaire, there is considerable progress has been made, although much has still to be done, owing to the opposition raised by the municipality of Brussels to the views put forward by the Government. In the girls' schools the exercises are accompanied by music, after the example set by Colonel Amoros, who about the beginning of this century introduced into France a series of gymnastic exercises adapted to a jingling rhyme and to music. The clashing governor the movements, marked the intervals of repose, and helped to strengthen the organs of the voice and respiration.

In France the necessity for the physical education of the people began to attract attention about the year 1845, owing probably to the energy display of by John in Prussia. M de Salvandy proposed to introduce the teaching of gymnastics into the Lycées of Paris and Versailles, and a commission was appointed by him, which, however, never presented a report. In 1850, 1851, 1855, and 1856 several attempts were made to enforce compulsory gymnastic training, but the principle was not accepted till 1859, when M V Darcy took for his basis of action the labours of the commission presented over by Dr Hillanet. After the fall of the empire, M Jules Simon addressed the head masters of the colleges and schools in France as follows—

"I beg you to assist me in introducing gymnastics into our habits in a profitable and tasteful manner. This is not only in the interest of public health, a healthy child is better prepared for study, and especially for the battle of life. Morality gains by this education of the body, much money is not wasted for the purpose, and in case of need, exercises can be performed without a trapeze or dumb bells. Our medical men will help us to do our task, if the children are once accustomed to, and take pleasure in, these healthy exercises, we may be sure of a prompt amelioration of the race."

In England we find that the first attempt to introduce scientific physical education among the people was made in parliament in 1862 by Lord Eiche. This attempt failed, as also did another made in 1875 by P A Taylor, M.P. for Leicester, although supported in an able speech by Mr Butler Johnstone. Lord Sandon, then vice-president of the committee of council on education, told Parliament that "the Government has done all that could be expected of them for physical education by taking steps to substitute military drill for ordinary drill." The substitution, it may be remarked, does not appear to have any advantage over the drill it displaced, as the military authorities declared the ordinary military drill to be insufficient for the use

guements of the soldier, and have during the last sixteen years instituted gymnastics at Aldershot, Gibraltar, Malta, and elsewhere, the teachers in which have, for the most part, passed under the care of Mr MacLaren of Oxford, one of the principal authorities on the subject in England. Without entering into details, it may be admitted that the physical condition of the people, if not actually deteriorating, is not improving, and it is a significant fact that within the last year or two it has been found necessary to lower the standard in the British army, and that Dr Ord, in his report for 1869, states that out of 5567 boys 4410 were rejected as under the standard of width of chest and height. We have already referred to the tendency to rely on the casual outdoor sports for maintaining the physique of the population, and to a great extent to discontinue systematic gymnastic exercises and physical education. That in some quarters, however, this opinion is not entertained is shown from the fact that the London School Board has appointed Miss Lofving of the Stockholm Training College to instruct certain of their teachers so as to fit them for teaching the girls in the schools. It is to be regretted that in the blind asylums so little is done for the physical education of the inmates. An institution in Milan provides for the training of ricketty children by carefully regulated gymnastic exercises, but this institution seems to be the only one of its kind in Europe.

To show that the importance of gymnastics has not been overestimated, we may describe the effects produced on twelve non-commissioned officers sent by the military authorities to be trained as teachers for the British army by Mr MacLaren. The men ranged from nineteen to twenty-nine years of age, and in height from 5 feet 5 inches to 6 feet. In Mr MacLaren's own words, "the muscular additions to the arms and shoulders and the expansion of the chest were as great as to have absolutely a ludicrous and embarrassing result; for, before the four months several of the men could not get into their jackets and tunics without assistance, and when they had got them on they could not get them to meet down the middle by a hand's breadth." In a month more they could not get into them at all, and new clothing had to be procured, pending the arrival of which the men had to go to and from the gymnasium in their greatcoats.

Although there is some diversity of opinion among teachers of gymnastics as to the relative value of the different exercises, some holding that "free exercises" are sufficient, others, that certain mechanical appliances are necessary, yet all agree that, to ensure the fully and perfect development of the organs of the body, a course of gymnastics must commence with such exercises as those as walking, running, jumping, &c. The introductory course ordinarily consists of "movements and positions" and the use of dumb bells and bar bells. In some French gymnastics, especially those introduced by M. Legerre, of Paris, an instrument is used and called by him "a *gilette*," as in use, consisting of a wooden stick, not notched and weighted with a rod of iron, and corresponding apparently to the bar bell of English teachers. Another form of mechanical apparatus, also in use in some Continental schools, consists of sticks on which slide wooden spheres of from 6 to 7 inches diameter, prevented from slipping off by india-rubber rings at each end. The movements which accompany the use of the stick are intended to expand the chest and increase the power of the muscles of the back. In stretching the arms outwards from the bent position, the spheres fly outwards and very much increase the energy of the movements.

For the preliminary exercises with movable apparatus, the dumb bell is that usually selected. It was in use in England in the time of Elizabeth. It has many advantages over the Indian club, the weight of the dumb bell requiring a less amount of room, and not presenting the risk the club does of overstraining the body by its unwhisked use.

The dumb bell admits of being exactly proportioned to the individual strength of each learner, and can be adjusted in weight as its strength increases. The exercises also that may be performed with it give employment to all parts of the body and to both sides equally. The bar is simply a two handed dumb-bell. Next in order come walking, running, and jumping, the exercises being so regulated that both the distance and speed are gradually increased. The *leaping rope* is suspended from a beam, and enables the leaper to

clear a barrier at the same time that it gives employment to both the upper and lower limbs. The *leaping pole* is usually made of ash, and is used from 8 to 10 feet in length. Its use may be left to the pleasure of the pupil after he has acquired some dexterity with the leaping rope.

The *horizontal beam* is a round wooden beam so mounted that it may be moved up and down. The exercises on this are chiefly balancing the body in the sitting and erect posture, and when moving along it.

The *vaulting bar* differs from the preceding in being somewhat thicker, so as to be easily grasped by the hand. The appropriate exercises on this are for the strengthening of the muscles of the upper extremity and joints. The *vaulting horse* allows of a wider range of exercises, and requires a greater amount of strength and dexterity. The muscles of the upper and lower limbs and trunk are all benefited by its use. The *fixed parallel bars* are used to develop the muscles of the trunk and upper limbs, but chiefly the former. The *movable parallel bars* may be used for the same exercises as the preceding. The *trapez* consists of a horizontal bar suspended by ropes at a height of 4 or 5 feet from the floor. Considerable practice is required to perform the exercises on this machine with dexterity and neatness. The *horizontal bar*, the *side ladder*, the *plank*, the *vertical plane*, the *prepared wall*, and the *rope*, and several modifications of these that may be used, present of a great variety of exercises.

In "exercises," the exercises are more directed to ensure grace and ease in the several movements of the body than muscular development and are, therefore, closely allied to the "movements and positions" or "free exercises" of the gymnast. Among these exercises dancing takes a prominent part, being at once beautiful and graceful.

See Combe's *Education, its Principles and Practice*, edited by J. C. MacLaren's *Physical Education*, the various works (in French) of Prof. N. Lenoir, Capt. Doer, and Dr. Le Blond, and numerous pamphlets by Dr. Boeth.

GYMNASTICS See **EXERCISES** and **ELECTRICITY**.
GYNECOLOGY (from the Greek *gynē*, a woman, and *lógos*), that branch of medicine which concerns the pathology and treatment of affections peculiar to the female sex. See **MEDICINE**.

GYOMA, an old market-town in the Trans-Tisane county of Békés, Hungary, is situated on the banks of the Körös main stream, 46° 57' N lat, 20° 50' E long. It has a fine town-hall, Roman Catholic, Calvinist, and Lutheran churches, a Jews' synagogue, tax, post, and telegraph offices, a brewery, several elegant private residences, and a large station on the Szolnok And Railway. The soil of the surrounding country, though in some places clayey, is in others of a rich and productive character, and the inhabitants succeed in raising plentiful crops of wheat, mangrove, barley, millet, and maize, besides cultivating several kinds of orchard fruit and grapes. The more considerable landholders can great numbers of sheep, pigs, and hound cattle. An abundant supply of fish and water-fowl is yielded by the Körös, which is here spanned over by a wooden bridge and by the railway. Enormous quantities of firewood are floated down the stream on rafts. The fields are protected from floods by a large dike, while a similar service is rendered by the Nagy-Iván, Csengelyi, Jókai, and Német trenches, which usually become dry during summer. In 1870 the population of Gyoma was 9907, by nationality Magyars. Before 1683 there other communes, viz, Eger, Pó, and Nyírszég, stood on the wide-spreading tract belonging to Gyoma. In that year they were, however, completely destroyed, and now only traces of their former existence remain.

GYONGYOS, the second town in importance of Heves county, Hungary, is situated at the foot of the Mátra, south west of Eger (Erlau), and is connected by a branch line with the Budapest-Miskolc royal state railway, 47° 47' N lat, 18° 19' E long. Gyongyos is the seat of a court of justice, and of a board of taxes, and contains three churches, a large monastic establishment belonging to the Franciscans, a gymnasium, manufactures of leather, hats, and woollen cloth, and distilleries. The town carries on a brisk trade, especially in the Viscontar and Eger (Erlauer) red wines, which are produced in great quantities in the

neighbourhood. In 1870 the population was 15,830, mostly Magyars by nationality. The Hungarians defeated the Austrians at Gyugyos on the 3d April 1849.

GYONGYOSI, ISZVÁN or STEPHÁN (1620–1704), one of the most talented Hungarian poets of the 17th century, was born of poor but noble parents in 1620. The county of his birth is variously given as Gomoj or Bona, the date as August 5 or November 3. His abilities early attracted the notice of Count Ferencz Wesselenyi, who in 1640 appointed him to a post of confidence in Füleu castle. Here he remained till 1653, when he married, and commenced his public career as an assessor of the judicial bench. In 1661 he was elected as a representative of his county at the diet held at Soprony (Oedenburg). From 1686 to 1692, and again from 1700 to his death in 1704, he was deputy lieutenant of the county of Günsör. Of his literary works the most famous is the epic poem *Mindya Venus* (Canelan, 1664), which hymns the praises of his benefactor's wife Maria Szécs, the heroine of Matiny. Among his later productions the best known are—*Ritza-Kus orit*, or *Rosa-Wreath* (1690), *Kemény-János* (1693), *Cupidó* (1695), *Palnoudus* (1695), and *Cherikha* (1700). His poems are chiefly remarkable for energy, feeling, and popular sentiment. The earliest edition of his collected poetical works is by Dugonics (Pressburg and Pesth, 1796), the best modern one that of Földi, entitled *Gyongyosi István elegantiás poétai munkái* (Select poetical works of Stephen Gyongyosi), 2 vols., 1864–65.

GYPSUM, the hydrated sulphate of lime, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$, is a mineral substance occurring in various rock formations, especially in Tertiary deposits, in very considerable abundance and under varying conditions. In its transparent crystalline state it is known as selenite, when it presents a finely fibrous opalescent appearance, it is termed satin spar, and the name alabaster is reserved for the pure milky white massive varieties. Gypsum is very generally disseminated, the most famous locality for the finest qualities worked into alabaster vases and figures being Constantin, about 30 miles from Leghiora, while Montecatini, Argenteau, and other places in the environs of Paris, and in the neighbourhood of Derby in England, furnish inexhaustible supplies chiefly for the preparation of plaster of Paris and for agricultural use, &c. It is also found in large quantities in Nova Scotia, New York, Virginia, and Michigan. The application of gypsum as a manure is referred to under AGRICULTURE, vol. 1 p. 351, and its employment for ornamental purposes is described under ARCHITECTURE, vol. 1 p. 439. The preparation of plaster of Paris, so called from the fact that the industry chiefly centres in several Parisian suburbs, is the principal object of the quarrying or mining of gypsum. By the application of heat gypsum begins, at a temperature of about 173° Fahr., to part with its combined water. An increase of temperature causes the desiccation to proceed with great rapidity, and for manufacturing purposes the best results are obtained at from 230° to 250°. For making plaster of Paris, gypsum is burnt in kilns at about the latter temperatures, and subsequently it is powdered and ground to a fine uniform flour. So prepared it possesses the valuable property of recombining with water when mixed with it, and setting, from a thin paste, into a solid mass, the phenomenon being accompanied with some expansion and the evolution of heat. It is to this property of recombining with water that the value of plaster of Paris is principally due. When, however, gypsum is burnt at a temperature of 480° and upwards, the sulphate rehydrates only with great difficulty, and at still higher temperatures it loses all power of absorbing water, and in this respect it then resembles anhydrite, the natural water-free sulphate of lime. Plaster of Paris is largely used for obtaining copies of statuary figures, coins, medals, sculptures, and

carvings, and also for taking casts from natural objects. It is also employed as the material for moulds for electro-deposits, and for the manufacture of enbossed and pressed pottery ware. Still more extensively it is consumed in the finishing of internal plaster work in houses, and for making cornice moldings and other architectural enrichments in positions sheltered from the weather. Plaster of Paris work is, like gypsum, soluble in water at a temperature of 32° to the extent of 205 per cent., rising to a maximum solubility of 254 at 95° Fahr. Plaster casts made simply with water are soft, porous, and easily injured, and various plans have been devised for producing a harder and more compact body with plaster. Keene's cement, which may be taken as a type of the hardened plasters, is made by treating the burnt gypsum with a solution of 1 part of alum to 12 of water at a temperature of about 95°. After about 3 hours the plaster is removed, dried, and rebaked in the furnace, and then thoroughly ground and powdered. Thus prepared, the plaster needs comparatively little water to slake it, and it sets much more slowly than the ordinary plaster, while the comparative tenacity of the two varieties is as 15 to 1. Putian cement is plaster hardened with water containing 10 per cent. of borax, and stucco is plaster rendered tenacious by being prepared with a strong solution of glue. When water containing lime or a solution of gum arabic is used to slake burnt gypsum, a hard plaster is also obtained, which by smoothing, colouring, and subsequent polishing with oil assumes a marble-like surface. A fine imitation of mersschmuss is also made in hardened plaster by polishing, tinting the surface with a solution of gamboge and dragon's blood, and treating it with either melted paraffin or stearic acid. It is understood that the cheaper "mersschmuss" pipes and cigar-holders are thus prepared.

GYROSCOPE, GYROSTAT, are names given to instruments which are used to demonstrate certain properties of rigid bodies, when made to rotate rapidly about the axis round which they are kinetically symmetrical.

In some of its forms the gyroscope has been known for a very long time, and is, in all probability, of French or German invention. Almost the first instrument of the kind that we hear of, and of which the present gyroscope is merely a modification, is that of Bohnenberger, which was constructed as early as 1810, and is described in Gilbert's *Annalen* for 1818 (ix p. 60). It consisted of a heavy spheroid which could rotate inside a circular ring round its shorter axis, the axis running on pivots situated at opposite ends of the ring's diameter. This ring, with its contained spheroid, was similarly made movable inside a second ring, and round an axis at right angles to the axis of the spheroid. In the same way this second ring, with its contents, could rotate inside a third ring, and round an axis at right angles to each of the others. From this it will be seen that the spheroid had all degrees of free rotation,—one point only within it being fixed, namely, the intersection of the three axes.

Under the title of precession instruments, various pieces of apparatus, involving the gyroscope principle, have been in use for a number of years for illustrating the precession of the equinoxes, and the parallelism of the earth's axis as it revolves round the sun. An instrument of this kind was given by Arago to Professor Playfair, which must have been in existence since 1816. Mention is made of a similar instrument as being brought from Italy to Mr. Babbage in 1837. At the close of that year a notice of an instrument akin to the gyroscope made by Mr. Henry Atkinson was read before the Astronomical Society. In 1856, in a paper read before the Royal Scottish Society of Arts, Mr. Edward Sang, C.E., Edinburgh, suggested an experiment with an instrument exactly similar to the gyroscope, by which the rotation of the earth on its axis could

be directly proved. He says, "While using Troughton's top an idea occurred to me that a similar principle might be applied to the exhibition of the rotation of the earth. Conceive a large flat wheel, poised on several axes all passing exactly through its centric of gravity, and whose axis of motion is coincident with its principal axis of permanent rotation, to be put in very rapid motion. The direction of its axis would then remain unchanged. But the directions of all surrounding objects varying, on account of the motion of the earth, it would result that the axis of the revolving wheel would appear to move slowly." This suggested experiment was actually carried out in 1853 by M. Leon Foucault, although, in all probability, without any knowledge on his part of M. Saug's suggestion. Already, in 1851, Foucault, in his famous experiment with the pendulum at the Pantheon in Paris, had shown how the constancy of the plane of a pendulum's vibration could be used to show the rotation of the earth, and now, in 1853, he applied the property of the "constancy of the plane of rotation" of a gyroscope for the same purpose. The name gyroscope was given to the instrument by Foucault at this time, and in order to perform the experiment successfully the instrument had to be constructed with the utmost exactness. The experiment was repeated at the Liverpool meeting of the British Association, and by causing a considerable sensation in the scientific world at the time was the means of bringing the gyroscope into public notoriety. In *Poggendorff's Annalen* for 1858 there is a description of a gyroscope made some time before by Fessel, and about the same time we hear of various modifications of the instrument introduced by Prof. Baden Powell, Wheatstone, and others. Quite recently, in 1878, there has appeared in the *Scientific American* an account of a new form of gyroscope made by Mr. C. M. Hopkins. In this instrument the heavy flywheel is driven by an electric current after the manner of an electromotive engine, and so its rotation can be kept up for any length of time.

The construction of the gyroscope will be readily understood from fig. 1, which is engraved from a photograph of a large instrument made by M. Saug.

It consists of a fly-wheel, with a heavy rim accurately turned and balanced, which can rotate round an axis GO forming a diameter of the ring K. This ring also can rotate about the axis AF which is at right angles to GO, and is a diameter of the ring L. Similarly this ring L can rotate about the vertical axis BII, which is perpendicular both to GO and AF, and forms a diameter of the ring M, which is screwed to the heavy sole plate N. In order to perform certain experiments the ring M, by means of a clamp arrangement seen at X, can be turned round to make the axis BR inclined at any angle with the vertical. With this instrument the following among many interesting experiments may be made.

1. Either by a large fly-wheel and band, or by running out a long cord coiled several times round the V grooved wheel on the end of the axis, let a very rapid rotation be given to the fly-wheel round the axis OC, and in the positive direction (that is, counter-clockwise as seen from C). Such a rotation can readily be given so rapid as to last a long time. While so revolving let a weight be placed at G so as to cause a rotation round OA, also in the positive direction, and it will then be observed that a slow rotation of the whole mass takes place about the vertical axis OB, but in the nega-

tive direction. If the weight be put at C, the wheel rotating as before, the rotation round OB will be in the positive direction. Reversing the rotation of the wheel will in both cases produce a reversal of the rotation round OB.

2. The fly-wheel still rotating in the positive direction, let a positive rotation be given to the ring L round OB, and immediately the axis of the wheel OU will tilt up, rotating in the positive direction round OA till it reaches the vertical position, where it will remain, and then it will be observed that the fly-wheel is rotating in the positive direction round OB. Should the axis OC, in consequence of inertia, be turned a little past the vertical, and the direction of rotation round OB be then suddenly reversed, the axis OC will continue to revolve in the positive direction round OA, till it reaches the vertical pointing downwards, when it will again be stationary, and the wheel will now be rotating in the negative direction round OB. By gently oscillating the ring L at the instant the axis of the fly-wheel is passing the vertical, a continuous rapid rotation round OB can be given to the ring K carrying the rotating fly-wheel with it.

3. Let the fly-wheel be now made stationary, and, while in this position, let simultaneous rotations in the positive direction be given round both OA and OB, the fly-wheel will then be observed to begin to move in the negative direction round OC.

The explanation of all these experiments follows readily from the theory of the composition of rotations round different axes. Let the angular velocities about O A, O B, O C, be ω , ω' , ω'' respectively. If simultaneous angular velocities ω and ω' be given round OC and OA in the positive direction, these can be compounded into an angular velocity about a new axis OI, which divides the angle AOC into two parts such that

$$\omega = \sin COI \sin COI - \sin COI - \tan COI = \tan \theta \text{ (suppose.)}$$

OI is, therefore, the position of the instantaneous axis, and as OC will always tend to coincide with it, OC will move round the axis OB in the negative direction. It will be noticed also that, ω remaining the same, $\tan \theta$ will be less as ω' grows. This shows that the rotation round OB, at the motion in arimuth, will be slower as the speed of the fly-wheel is greater. This accords with experiment. In precisely the same way by considering simultaneous angular velocities about OB and OA and OB, can experiments 2 and 3 be explained.

Perhaps the most common form of gyroscope is that which has been largely sold under the name of the gyroscope top.

It is a modification of the gyroscope introduced by Fessel. In it the ring containing the rotating wheel is either supported on a vertical pivot at the end of the axis, or simply held suspended by a string attached to the same point, as represented in fig. 2. In this case, when the wheel is rapidly rotated, and its axis initially inclined at an angle with the vertical, a slow motion round the vertical axis is observed to take place. This

Fig 2

rotation is accompanied by a feeble nutation of the axis, which is unobservable by the eye so long as the wheel rotates rapidly. The rotation in arimuth would continue uniform if the velocity of the wheel is maintained constant, but irregularly increases in speed, the nutation at the same time becoming more apparent as the velocity dies away, till the gyroscope finally settles with the axis of the wheel in the direction of the

Fig 3

settles with the axis of the wheel in the direction of the

longation of the supporting string. A short analytical investigation of this particular case may serve to give some of how problems on the gyroscope generally may be tackled. For clearness in the woodcut (fig 3) we suppose ring containing the wheel removed.

at K represent the wheel of mass M , A the distance of the centre of gravity G from O , OC the axis of the wheel, supposed of unit length, OA , OB , two other axes through the fixed point O at right angles to OC and to each other, OX , OY , OZ three rectangular axes fixed in space, with which OA , OB , OC (axis able with the body) initially coincide, ψ , ϕ , θ , angles on the sphere which define the position of G . $\dot{\psi}$, $\dot{\phi}$, $\dot{\theta}$ the angular velocities about OA , OB , OC respectively, the equation of kinetic energy T gives

$$T = \frac{1}{2}(A\dot{\psi}^2 + B\dot{\phi}^2 + C\dot{\theta}^2) \\ + \frac{1}{2}M\dot{\psi}^2 + \frac{1}{2}M\dot{\phi}^2 + \frac{1}{2}M\dot{\theta}^2$$

differentiating and making $A = B$, as is clearly the case, we have $T = \frac{1}{2}A\dot{\psi}^2 + \frac{1}{2}A\dot{\phi}^2 + \frac{1}{2}M\dot{\theta}^2 + 3C(\dot{\psi}\dot{\phi}\dot{\theta} + \dot{\psi}\dot{\theta}\dot{\phi} + \dot{\phi}\dot{\theta}\dot{\psi})$

giving Lagrange's equations of motion, which are for this case

$$\frac{d}{dt} \frac{\partial T}{\partial \dot{\psi}} = \frac{\partial T}{\partial \psi} = 0, \\ \frac{d}{dt} \frac{\partial T}{\partial \dot{\phi}} = \frac{\partial T}{\partial \phi} = 0, \\ \frac{d}{dt} \frac{\partial T}{\partial \dot{\theta}} = \frac{\partial T}{\partial \theta} = Mgh \sin \theta,$$

giving

$$(1) \frac{d}{dt} \left\{ A\dot{\psi} \sin^2 \theta + C(\dot{\psi}\dot{\phi}\cos\theta + \dot{\phi}\dot{\psi}\cos\theta) \right\} = 0,$$

$$(2) \frac{d}{dt} \left\{ C(\dot{\psi}\dot{\phi}\cos\theta + \dot{\phi}\dot{\psi}\cos\theta) \right\} = 0,$$

$$(3) A\ddot{\theta} - A\dot{\psi}^2 \sin \theta \cos \theta + C\dot{\psi}\dot{\phi}(\dot{\psi}\cos\theta + \dot{\phi}\sin\theta) = Mgh \sin \theta$$

giving (2), we get

$$\dot{\psi}\dot{\phi}\cos\theta + \dot{\phi}\dot{\psi}\cos\theta = a \text{ constant} = n,$$

which represents the angular velocity about OC owing to the motion being steady we must have both $\dot{\theta}$ and $\dot{\phi}$ constants which can be represented by α and μ respectively. Then equation (1) becomes

$$-A\mu^2 \sin \alpha \cos \alpha + C\mu \sin \alpha = Mgh \sin \alpha \\ \mu = \frac{Mgh + A\mu^2 \cos \alpha}{C}$$

this formula we can calculate, for any particular instrument, the velocity in azimuth from having given the angular velocity of rotation of the fly-wheel and vice versa.

An important case of motion, and one also very interesting both mathematically and physically, is got by including the gyroscope in a pendulum bob and supporting the rod from a universal flexure joint. This constitutes the gyroscope pendulum. The joint is usually got by attaching a short piece of fine steel wire rigidly to the end of the rod, and bending the whole by means of the other end of this wire firmly clamped into a fixed support. When the scope is rapidly rotated, and the pendulum drawn aside from the vertical and then let go, its lower end is observed to describe a beautiful curve consisting of a series of equal closed loops, all equally near each other and arising from a centre point. This curve, which is a case of hypotrochoid, is figured in Thomson and Tait's *Great Philosophy*, where also the whole theory of the scope pendulum will be found.

It has been already mentioned, a remarkable apparent effect is produced by the earth's diurnal rotation upon a fly-wheeling gyroscope. This is seen from what Foucault called the "fixity of the plane of rotation," and what Thomson and Tait have recently called "gyrostatic dominion." In virtue of this principle, the axis of the rotating wheel tends always to preserve a fixed direction in space, and, in consequence, will appear to move in a direction opposite to that in which the earth's rotation is at each instant actually carrying it.

We suppose the gyroscope represented at fig 1 to have all its axes of free rotation round the point O , and to be in every way fly balanced about that point, and also to have all its pivots

nearly round of friction, then, as when a part of the earth's surface it may be placed, the fly-wheel while rotating rapidly will be observed to move gradually and finally take up such a position that its axis OC is parallel to the earth's axis, and also that its direction of rotation round OC is the same as that of the earth round its axis. Should the ring K be fixed so that the axis OC can only move in a horizontal plane, then the ring L will move in azimuth till it has placed OC in the direction north and south and such that the direction of rotation of the fly-wheel coincides with that of the earth. Further, should the ring L be fixed in the plane of the meridian, so that OC can only move in altitude, then OC will be observed to tilt up till it is parallel to the earth's axis, the direction of rotation of the wheel being, as before, the same as that of the earth. These effects may be explained as follows—

Let α be the latitude of the place, and ω the angular velocity of the earth on its axis, also, ω being the ring L in the horizontal plane, and let OC make an angle θ in azimuth with a horizontal line ON drawn from O northwards, finally, let the rotation of the wheel round OC be positive. Now as OC is revolved into three singular velocities at right angles to each other, it is

$$\omega \sin \alpha \text{ round the vertical line,} \\ \omega \cos \alpha \text{ round a line parallel to } ON \text{ and}$$

Of these $\omega \sin \alpha$ gives the velocity in azimuth, $\omega \cos \alpha$ can only affect the velocity of the wheel, while $\omega \cos \alpha$ sin α gives the velocity of OC in altitude. These being the actual component velocities communicated to the gyroscope by the earth, the opposite velocities will be equal and opposite to them.

The apparatus actually employed by Foucault to demonstrate the rotation of the earth differed somewhat from that represented in fig 1. In it the corresponding ring to L was suspended from a fixed stand by a thread without torsion, and rested at its lowest point by a pivot in an agate cup. Also the ring corresponding to K , which carried the fly-wheel, rested on knife edges within L , and could be removed at pleasure, in order that the rotation might be given to the fly-wheel. Great care was also taken to have every part thoroughly well balanced. It is stated that the experiment was several times successfully performed, and Foucault by means of his apparatus was thus able to verify astronomical observation, to find out the latitude of the place, the east and west points, and the rate of the earth's motion. The same experiment has lately, it is said, been successfully performed by Mr G. M. Hopkins. His fly-wheel, being driven by electricity, has the advantage of rotating at a uniform rate for any length of time. By attaching a small mirror to the frame which carries the revolving wheel, and using a spot of light reflected from it as an index, he has been able to make manifest the earth's rotation in a very short time.

An ingenious practical application of the gyroscope principle was suggested and carried into effect about the year 1855 by Professor Piazzi Smyth. His aim was to devise a telescope stand which would always remain level on board ship, notwithstanding the pitching and rolling, and so facilitate the taking of astronomical observations at sea. For this purpose the stand was supported on gimbals, and underneath it was placed on fine pivots several heavy fly-wheels which could be put in rapid rotation, some on vertical and some on horizontal axes. The complete apparatus, involving many ingenious details as to driving the fly-wheels, was tested by Professor Piazzi Smyth on board the yacht "Titanic" during a voyage to Tenerife, and found to work with perfect satisfaction. A full account of the method will be found in *Trans. Royal Scottish Society of Arts*, vol. 17.

GYROSTAT.—This is a modification of the gyroscope, devised by Sir William Thomson, which has been used by him as well as by Professor Tait for a number of years to illustrate the dynamics of rotating rigid bodies. It consists essentially of a fly-wheel, with a massive rim, fixed on the middle of an axis which can rotate on fine steel pivots inside a rigid case. The rigid case is exactly like a similarly-shaped, but hollow, fly-wheel and axis closely surrounding the other but still leaving it freedom to move. XI — 45

containing case whereby a cord can be coiled several times round the axis for the purpose of setting the fly wheel in motion. There is also attached to the rigid case, in the plane

passing through the centre of gravity of the wheel at right angles to its axis, a thin flange of metal, which is called the bearing edge. The circumference of this flange is not a circle but a convoluted polygon of sixteen or more equal sides. The object of making it so is to prevent the instrument from rolling like a wheel on the bearing edge when the fly-wheel is rotating rapidly. A drawing of the gyrostatis, with a portion of the case removed to show the inside, is given in fig 4. A represents the bearing edge upon which the whole balances. To suit certain experiments, a sharp conical metal point can be fixed on to the end B by means of a bayonet joint.

The gyrostatis is a most instructive instrument, and with it many interesting experiments can be performed. We can only mention a few taken from Thomson and Tate's *Natural Philosophy*, vol. I, Part I, where the mathematics of the whole subject will be found fully given.

1. Let the gyrostatis be placed on a flat disc of glass with its bearing edge in a vertical plane as represented in the figure. Neglecting its weight, it lies in this position clearly two freedoms, one in φ and the other in θ . Of these, the first is neutral and the second unstable when the fly-wheel is still, but when it rotates rapidly the second will become stable, the first remaining neutral as before. When the fly-wheel is spinning, rapidly, the poise with which the gyrostatis keeps the erect position is very remarkable. A blow from the fist on the side of the case is met by a strong resistance, the instrument being thrown into a state of violent tremor, which subsides, however, after a few seconds. If, while the fly-wheel is still, rapidly spinning, weight be hung on B, the whole apparatus will, like the gyroscope, immediately begin to move round a vertical axis.

2. Let the gyrostatis be supported on knife edge gimbals at its lower end, and with the axis vertical. In this position it has two freedoms each unstable, without rotation of the fly-wheel, but with it both stable. A small result is obtained by supporting the gyrostatis on a universal flexure joint, constituting an inverted gyroscopic pendulum.

3. Let the gyrostatis be supported on two equally long slits perpendicular to the bearing edge. In this position the two freedoms, one φ and the other inclination, are both stable without, but both stable with, rapid rotation of the fly-wheel.

4. Let the gyrostatis be attached to a bar of wood by thrusting the bearing edge, through a narrow slot in the middle of the bar, and then let it be supported by strings attached to the ends of the bar, the bar being horizontal. By this we have the means of showing the gyrostatis behaving in four different ways, two with the wings parallel and two with them crossed, the gyrostatis being alternately above and below the wooden bar. Each of these ways has four freedoms, which can be reduced to three by a third string in each case. A little consideration will show in each case the stable and unstable modes without and with rotation of the fly-wheel.

It only remains to mention a very interesting and intricate gyrostatis problem which has been lately suggested by Sir William Thomson. He suggests a string of gyrostatis to be formed with them axes all in the same straight line, and each attached to the other by a small universal flexure joint of thin steel wire. If this string be disturbed after the fly-wheels have all been put into rapid rotation, a remarkable cork screw motion passes along the wire. For particulars we must refer to a paper announced by Sir William Thomson in the *R. S. Proceedings*.

GYTHIUM was an ancient Aeolian town on the Laconian Gulf, south-west of the mouth of the Eurotas, near the site of the modern port Manthotia. It lay opposite the island Ciane, at the foot of the fertile valley of the Gythius. On its coasts the common types are Apollo and Heracles, the founders of the city. Heracles, the Phoenician god Melkart, points to an early connexion with Tyre. The Phoenicians maintained a great trade with the shores of the Laconian Gulf, and Aphrodite Migonitis, the Phoenician Ashtar, had a temple at Migonion, the modern Manthotia. Aphrodite and Asclepius also occur on its coins, and the latter had a temple in the city. A great port in the period of Phoenician intercourse, Gythium became a secondary town after the Doron conquest, as is proved by the absence of early coins, and it was only after the decay of Sparta that it again became an important city. It was the ordinary station of the Spartan fleet, and was considered the port of the city, in which it was distant about 30 miles. In the wars against Athens it was therefore exposed to frequent attacks. Tolmides, the Athenian commander, burned it (455 B.C.). Later it was besieged unsuccessfully by Epaminondas (370 B.C.). It was strongly fortified by the tyrant Nabis, but he was compelled by Flamininus to give up Gythium and other coast towns to the Achaean league (195 B.C.). When, soon after, wars, the whole country became a Roman province, Gythium had its own magistrates, *stratagorai* and *hupoai* (see insc. in Lebes, *Voyage Archéol.*, 242a, and *Gott. Gel. Anz.*, 1865, p. 401). Augustus made it one of the twenty Ionian-Eleuthero-Laconian towns. The existing ruins, called Paleopolis, are all of the Roman period. According to Strabo (p. 363), it had an artificial harbour, of which Cal Leake could see no trace. In the town was a well sacred to Asclepius, and at three stades distance was the stone Argos, where Orestes was relieved from his madness.

GYULA, chief town of the Trans-Tibetan county of Dékda, Hungary, is favourably situated on the Fehér (White) Körös, and has a well-built station on the Nagy-Tiand (Grossvárden) and Eszék line of the Alföld-Fiume Railway, in 46° 38' N lat., 21° 17' E long. The outer ditch of the old ruined fortress, the tower of which serves as a prison, divides Gyula into two parts, named respectively Magyar Város (Hungarian town) and Német Város (German town). Stone bridges facilitate communication over the canal, which flows from the Körös, and intersect the streets. Among the principal buildings are Roman Catholic, Old United Greek, Lutheran, and Calvinist churches, and a Jews' synagogue, also a fine castle with gardens, a county hall, an ancient Turkish bath, many handsome private residences, and several oil-mills. Gyula is, moreover, the seat of the county assemblies and administration, of a royal court of justice, of the assizes, and of a board of taxes, and has post and telegraph offices, and a savings-bank. The inhabitants are employed partly in industrial and commercial pursuits, partly in farming and cattle-breeding. The fairs are much resorted to for the purchase of corn, horned cattle, sheep, pigs, wooden wares, and gall-nuts. The chief agricultural products of the surrounding country are wheat, barley, oats, and maize, there is also a good supply of garden fruit, grapes, and vegetables. In 1870 the population amounted to 18,496, consisting chiefly of Magyars, Wallachs, and Germans.

H

H has varied in form from the Phœnician and old Hebrew symbol , called *Cheth*, only by the removal of the upper and lower horizontal lines. (For the oldest forms of the letter see *ARABICAN*.) The closed form is sometimes found in old Greek inscriptions, and, though less frequently, in South Italy.

Its value in Phœnicia was probably a continuous guttural sound—the sound which it had in Hebrew—resembling the German *ch*, and with no English counterpart. In Greece it represented nothing more than the spirant *h*, so long as a separate symbol to denote that sound was felt to be necessary. Afterwards it was generally employed to denote a second *s*-sound, under the name of *Etta*; probably it had before been called *Heta*. The time of this change varied in different parts of Greece. In the alphabet of the island of Thera we find *H* representing *s* as early as the 40th Olympiad, though it still sometimes retained its old value. At Athens the date was 408 a.c., and here the practice did not vary. But in most of the alphabets of Greece proper, of Peloponnesus, and of the Italian colonies, *H* still remained as the rough breathing; and as such it consequently passed into the Latin alphabet. It is possible that *h* in a very few Latin words, when it occurs as a medial sound (*e.g.*, *trahere, veho*), was a continuous guttural. But generally it occurs at the beginning of a word, and can hardly have been more than a breathing. Even as this it early became evanescent. During the classical period of Latin literature it was retained in the speech of educated men, doubtless in part by Greek influence. But in the popular speech it was rapidly disappearing as an initial sound; although it continued to be written, and indeed was often written wrongly, at the beginning of words where it had no place; *e.g.*, *unior* was written *hunior*, and the *h* has held its own in English spelling down to our day. The sound is almost completely lost in modern Italian.

It is not settled beyond dispute by what mechanism the *h*-sound is produced. The old view (held by Lepsius and others) is that *h* has a distinct position of its own, further back in the throat than the gutturals, in fact, immediately above the larynx,—that it is a *surd*, to which the corresponding sonant is the slight gurgle heard between words of which the first ends and the second begins with the same sound (*e.g.*, “go over”), if we take care to close the glottis between the two words but not to alter the position of the other vocal organs. A quite different view is held by Whitney, M. Bell, and others, that *h* has no distinct position of its own, but is sounded in or through the position of the following sound; for example, that in saying *ha* we do not put the vocal organs into two positions, one for *h* and one for *a*, but we put them into the position for *a*, and then produce the breath and the vowel without any change of position, the *h* being a mere expiration of breath through the open glottis; similarly *hi*, *hu*, &c., are produced with the vocal organs in the position for *i*, *u*, &c., respectively; in each case the vocal chords vibrate for the vowel after the expiration of breath, but there is no change made within the orifice of the mouth between the *h*-sound and the vowel. This view is at least a plausible one.

HAARLEM, a city of the Netherlands, the chief town of the province of North Holland. By rail it is 11 miles W. of Amsterdam, 19 S. of Alkmaar, and 20 N. of Leyden. Distant about 5 miles from the German Ocean, it communicates with the Zuider-Zee by the Spaarne and the IJ. The railway to Amsterdam was opened in 1839, and that to Alkmaar in 1867.

Haarlem is a typical Dutch town. The branches of the Spaarne and an extensive system of canals bring the ship-traffic into the heart of it, and turn its streets into so many quays. The roadways are paved with bricks; the houses have gable-ends with old-fashioned crow-steeps; and everything wears a decent and quiet aspect, which to one man is dulness and to another “aristocratic gravity and modest coquetry.” What the city lacks in liveliness it makes up by the interest of its historical associations and the number of its scientific and artistic institutions. The great market place especially has much that is worth seeing: the town-house and the cathedral of St. Bavo; the old meat market, a building of the end of the 16th century in the old Dutch style; the stadthouders’ place where in former times the burgesses used to assemble in arms; and the statue erected to Koster in 1856, when in Holland he was still generally considered the inventor of printing. St. Bavo’s is one of the most famous churches in the Netherlands. It is a cruciform structure completed in 1538, and makes a considerable impression on the spectator by the great length (about 426 feet) of its main axis and the height and steepness of the

roof. The tower is about 255 feet high. Within the lofty vaulting is supported by twenty very light columns, and there is a good deal of beauty about the perspective of its aisles. The organ, built by Christian Muller of Amsterdam between 1735 and 1738, was for some time the largest in the world, and is still celebrated for the sweetness of its tone, especially in the vox humans stop. It possesses four key-boards, 64 stops, and 5000 pipes, the largest of which is 15 inches in diameter. Among the monuments in the church are those of Bilderdijk the poet and the hydraulic engineers Christian Brunnings and Frederik William Conrad, the latter the projector of the sluices at Katwijk. In the belfry are the *damianites*, small bells presented to the town according to tradition by William I., the conqueror of Damietta. At the head of the scientific institutions of Haarlem may be placed the Dutch society of sciences (*Hollandische Maatschappij van Wetenschappen*) founded in 1752, which possesses very valuable collections in botany, natural history, and geology. Teyler's foundation (Teyler's Stichting), instituted in accordance with the last will of Pieter Teyler van der Hulst for the study of theology, natural philosophy, poetry, history, drawing, and

numismatic, has various auxiliary collections in the founder's private residence. The Dutch society of industry, founded in 1777, is still active and flourishing, with branches established all over the country. In 1871 it instituted a colonial museum, which along with the royal museum of modern art is accommodated in the pavilion formerly the residence of an Amsterdam banker, Hope, and acquired for the crown by King Louis Napoleon. The colonial museum presents a complete survey of the manifold products of the Dutch possessions in the East Indian Archipelago, and the royal museum has a collection of 250 pictures. Among the benevolent institutions of the city it is enough to mention the hospital for old men founded in 1608, and the beautiful Teyler's Hospital.

The staple industries of Haarlem have been greatly modified in the course of time. Under the counts of Holland cloth weaving and brewing were in a very thriving condition, but under Charles V they lost enormously in importance. While 2000 pieces of cloth had been manufactured annually in the end of the 15th century, 800 or 900 were the number for 1515, and the breweries diminished from 120 in 1494 to 95 in 1603, and by 1613 were no more than 77. After the revocation of the edict of Nantes, silk, lace, and damask weaving were introduced by French refugees, and in course of time these industries gave employment to 10,000 of the population. About the close of the 18th century this remarkable prosperity was a thing of the past, and it was not till after the Belgian revolution that Haarlem began to turn its attention to the various departments of manufacture in which it is now engaged. Cotton factories, carriage-works, bleach-works, cotton and silk dye works, a famous type foundry, oil-works, soap works, breweries, and a factory for preserved meats are among the more important establishments. The extensive workshops of the Dutch railway company are also of value to the town. One of the printing establishments has the reputation of being the oldest in the Netherlands, and publishes the oldest Dutch paper, *De Opzigt Haarlemmer Courant*. As market gardening, especially in the flower department, is largely carried on in the immediate vicinity, Haarlem is the seat of a flourishing trade in "Dutch roots," especially in hyacinths, tulips, fritillaries, sparres, and japonicas. A considerable business is also done in the butter, cheese, and other agricultural produce from the surrounding country.

Though the population of Haarlem has been steadily increasing since the beginning of the present century, it has not become so great as it was in the 17th. In 1570 the total was 20,772 souls, of whom 1836 were Dutchmen capable of bearing arms, 1215 Englishmen and Frenchmen, 1895 Germans, and 13,865 women and children. By 1622 it had increased to 30,455. A rapid decline took place in the 18th century, from 26,281 in 1748 the number sank to 21,227 in 1796, and by 1815 it was not more than 17,132. Seven years later we find 18,465 inhabitants, 31,667 in 1830, 34,012 in 1840, 25,852 in 1850, and 27,534 in 1860. The year 1871 showed 32,758, and three years later the number was no less than 35,692. In 1869—1870 there were 14,471 members of the Dutch Reformed Communism, 11,574 Roman Catholics, and 565 Jews.

Haarlem is mentioned in a register of the 10th century as *Harloun*. From Count Wilfrim II it obtained a charter in 1246, and in the course of the following centuries it rapidly advanced in prosperity. In 1492 the insurgents called the "bread and cheese folk," got possession of the town, but before the year was out it was recovered by the imperial general Duke Albert of Saxony. The year 1498 was witness of a great conflagration, and in 1500 the plague claimed its many victims. In 1559 Haarlem became a bishop's see. The prominent fact that its inhabitants took in the revolt of the Netherlands brought upon it an unparalleled disaster. Don Fred, the son of the Duke of Alva, died at the town with 80,000 men in December 1573, and after a siege, in which the burghers defended themselves with admirable and pious heroism, it was obliged

to capitulate in July 1573. The conquerors, in spite of their promise of mercy, took barbarous vengeance, and it was not till July 1877 that the town was recovered from their grasp by the prince of Orange. In its subsequent history the main events are the inundations of 1775 and 1791, the visit of the Russian emperor in 1787, and the quinquacentenary celebration of the invention of printing in 1823.

See E. ALLEN, *Geachtverhaal en beschrijving van Haarlem en de omringende landen op ons dagen onder mededeling van E. DEN, Zoon, en Geachtverhaal*.

HAARLEM LAKE, or HAARLEMME MEER, a commune of the province of North Holland, constituted by the law of 10th July 1850. It has an area of about 46,000 acres, and its population has risen from 7000 in 1860 to 13,602 in 1878. As its name indicates, the commune was formerly a lake, and, according to Amersfoofd, this lake was a tide of a northern arm of the Rhine which passed through the district in the 2nd time of the Romans. In 1581 the Haarlem Meer had an area of 6430 acres, and in its vicinity were three smaller sheets of water—the Leidse Meer or Leyden Lake, the Spaarne Meer, and the Oude Meer or Old Lake—with a united area of about 24,000 acres. The four lakes were ultimately incorporated into one by successive inundations, and by 1647 the new Haarlem Lake had an area of 36,400 acres, which by 1740 was increased to 42,000. As early as 1648 Jan Adriaanszoon Leeghwater proposed to drain and drain the lake, and similar schemes, among which those of Nikolaas Samuel Cingius in 1742 and of Baron van Lynden van Hemmen in 1821 are worthy of special mention, were brought forward from time to time. But it was not till 1836, when an important hurricane on the 6th of November drove the water as far as the gates of Amersfoofd, and another on the 25th of December sent them in the opposite direction to submerge the streets of Leyden, that the mind of the nation was turned so strongly to the subject. In August 1837 the king appointed a royal commission of inquiry, the scheme proposed by the commission received the sanction of the second chamber in March 1839, and in the following May the necessary law was passed. The first object was to dig a canal round the lake for the reception of the water and the accommodation of the great traffic which had previously been carried on the canal was made 38 miles in length, with a depth of 9 feet, and a width 130 feet on the west side of the lake and 50 feet on the east side. The preliminary works were not completed till 1846. The area enclosed by the canal was rather more than 70 square miles, the average depth of the lake was 18 feet 14 inches, and as the water of the natural outlet it was calculated that 1,000,000,000 million tons would have to be raised by mechanical means. A gigantic steam engine designed by Messrs J. Gibbs and A. Dorn of London was erected and named in honour of Leeghwater. It could raise 112 tons at each stroke and discharge 1,000,000 tons in 24 hours. The total weight of iron used for the engine, pumps, &c. was 610 tons, and the cost of the machinery and buildings amounted to £24,000. Two other engines of equal size and power were afterwards constructed by Messrs Harvey of Hayle and Messrs Fox and Co of Farnley, in Cornwall, the makers of the "Leeghwater." They were named respectively the Cingius and the Van Lynden. Pumping commenced in 1846, and the water was being raised by the 1st of July 1852. At the first sale of the highest lands about the lake on August 16, 1853, 782 hectares were bought for 675,000 florins, or 788 florins per hectare, but the average price after six days was low. The area of 42,000 acres recovered from the water has brought in 9,400,000 florins or about £780,000, so that the actual cost to the nation has only been 4,400,000 florins or £360,000, though the expense of the enterprise amounted to 13,787,377 florins or £1,080,000. The soil of the reclaimed land is very dry, and, in fact, most of it is sufficiently fertile, though in the lower portions there are barren patches where the scanty vegetation is covered with an odorous deposit. Corn, ready cattle, butter, and cheese are the principal produce. The lands which traverse the commune are bordered by pleasant looking farm houses built after the various styles of Holland, Friesland, or Brabant. Hoofdoord, Vennepoord, or Nieuw Vennep, Abbende, and the vicinities of the three great steam engines are the spots where the population is clustered most thickly. The first church was built in 1855, in 1877 there were seven. In 1854 the city of Leyden laid claim to the possession of the new territory, but the case decided in favour of the nation. Five of works on the Haarlem Lake is given by Govaert van Ende-gout, *De doekmaking van Lac de Harlem* (The Hague, 1849—1861, 8 parts, with plates). See also J. P. Amersfoofd, *Het Haarlemmer Meer*, Haarlem, 1857, published by the Amsterdam *Maatschappij Wetenschappelijke Letteren*.

HAABAKKUK (חִבְכּוּק), one of the minor prophets of the Old Testament, the eighth in order of the Masoretic text. The name of the prophet is peculiar to him, and occurs only in his own writing (i. in 1). As to its meaning there is some uncertainty, but it is probably a formation from a verb signifying to *embrace*, or *embrace*

(פֶּזֶר), and means "embraced" or simply "embrace" (Jerome, *P. ad Hab.*, Gesenius and Furst on the word). In the Septuagint and with the Greek fathers it appears in the form of Ἀμβακού, which would seem to indicate that the Hebrew was read and pronounced Habbakkuk (פֶּזֶר), the double *b* being changed for the sake of euphony into *mb*. The change of the *l* into *m* at the end of the word Bleek says is without analogy, but in the change of Beelzebub into Beelzeboul we have an analogous instance of the substitution of a liquid for a mite,—probably because to the Greek *en* it was not agreeable that a final syllable should begin and end with the same rough consonant. Of the prophet's personal history nothing is certainly known. In the inscription of his book he is simply called "the prophet," nor can we with certainty determine at what time he lived and prophesied. From the use of the word "my" in the subscription to the psalm in chap. iii, "To the chief singer on my stringed instrument" (ver. 19), it has been surmised that he was of the tribe of Levi, inasmuch as it is supposed from this that he held a place among those by whom officially the musical service of the temple was conducted, a place which only a Levite, it is alleged, could occupy. But this seems rather too much to build on the mere use of the word "my," nor is it quite certain that only Levites took part with stringed instruments in the service of song in the temple. King Heschiah, after his recovery from his sickness, composed a psalm of thanksgiving, and in reference to it he says, "We will sing my songs to the stringed instruments all the days of our life in the house of the Lord," for he "had said, What is the sign that I shall go up to the house of the Lord?" (Isa. xxxviii 20, 22), from which it may be inferred that others besides Levites might take part in the liturgical music of the temple. Weo these any truth in the assertion in the additions to Daniel in the Apocrypha that Habakkuk was sent by the Lord from Judea to Babylon with food for Daniel in the lions' den, this would give us the date of the prophet's activity, but on such a manifest fiction nothing can be built. According to one tradition the prophet was banished at Kulek in the tribe of Judah, according to another at Eulkeek (now Teluk) in the tribe of Naphtali.

The book of Habakkuk falls into two parts,—the former of which (chaps. 1 and 2) has the inscription, "The burden which Habakkuk the prophet saw," and the latter (chap. iii) the inscription, "Prayer" (or hymn) "of Habakkuk on Shyrgonoth." Both parts have reference to the same subject, the invasion of Judah by the Chaldeans, who are expressly named (i. 6). In both this is regarded as a chastisement from the Lord upon the people for their sins, but whilst in the earlier part the prophet appears as a reproof and denouncer of evil, in the latter he gives utterance to emotions of reverence, confidence, and joy in God as the Saviour of His people. In the former part the prophecy is in the form of a dialogue between Jehovah and the prophet. The prophet, deeply troubled because of the corruption of his people, cries to God and asks how long such a state of things is to continue (1-2-4), to which God replies in effect that He is about to bring on the sinful nation a heavy calamity by raising against them the Chaldeans—"that bitter and impetuous nation"—whose fierce and terrible hosts should devastate the land,—at the same time intimating that such a scourge should pass away, and that the invaders, though the instruments of God's vengeance, should not be held guiltless (5-11). The prophet then appeals to God, the Everlasting and Holy One, and asks how the employment of such instruments to inflict punishment on the people of His choice is reconcilable with the divine clemency and unchangeableness (12-17), but declares that he will stand on his watch-tower that he may learn what God will say to him, hoping that some word of comfort may be vouch-

sured to him which he may carry to his people. The word comes, the Lord will not suffer the ungodly, the transgressor, and the idolater to escape, a five-fold war is denounced against the enemies of God's people, the just are encouraged to abide in faith, cheered with the assurance that as a result of God's judgments on the wicked the knowledge of the glory of the Lord shall fill the earth as the waters cover the sea, for God is in His holy temple, His purposes shall stand fast, therefore let all the earth be still and await His coming (1-1-30). The latter part of the book is a hymn of praise in which the prophet in his own name and that of the people celebrates the mystery and mighty deeds of the Lord, and gives exulting expression to the confidence and joy with which His true subjects rest in Him (in 1-19). This hymn is in form and style like one of the Psalms, and was doubtless intended for use in the temple service. To some it has appeared that this third chapter is wholly unconnected with the two preceding. But though different in character and style, it stands closely connected in substance with what goes before, and forms with this one whole. In the former part we have the burden which the prophet had to bear to the people, in the latter we have the utterance of the feelings produced by the contemplation of the facts and revelations therein set forth, viewed in the light of God's manifestations of Himself on behalf of His people in former times. The hymn, as generally agreed, was written by the prophet himself, forms one of the finest remains of ancient Hebrew literature. In conception and style it is not inferior to any production of the most flourishing age of prophecy. The language is pure, the thought is lofty, and in the construction a classic skill is displayed. With the mantle of the prophet the author dons also the chaper of the poet.

At what time Habakkuk prophesied remains uncertain. From 1. 5, 6, where the invasion of Israel by the Chaldeans is represented as a thing so strange as to be unaccountable when announced, it has been surmised that the prophecy was uttered whilst the people of Israel were unacquainted with the Chaldeans as a hostile power,—long, therefore, before the battle of Carchemish (606 B.C.), in which Nebuch, king of Egypt, was defeated by Necho, king of Egypt. The date of the prophecy has accordingly by some been referred to the reign of Manasseh, and this has been supposed to receive confirmation from the fact that during that reign there were prophets who foretold the coming on the nation of a calamity such as that the eyes of all who heard of it should meet (2 Kings x. 10 f.), and of these prophets Habakkuk may have been one. The words of the prophet, however, do not necessarily imply that at the time he uttered his prophecy the people were ignorant of the Chaldeans, and they could not be ignorant of what he was commissioned to announce to them regarding an invasion of the country by that "bitter and impetuous" nation; it is rather the imminence and suddenness of the catastrophe which he represents as what it would seem to be, even when announced by a prophet of the Lord. It is further to be observed that his words imply that the calamity he was sent to announce would happen in the days of those to whom he spoke, which could hardly be said of a generation that had reached old age during the latter half of Manasseh's reign, that is, fully sixty years before the invasion of Judah by Nebuchadnezzar. It may be added that it is very improbable that during the reign of Manasseh, when idolatry's reign and influence was at the height, the worship of Jahveh, such a pillar as that of chap. iii. would have been composed for the temple service by any one living in Judah. A later date, it would thus appear, must be assigned to the prophecy. Vitringa has suggested that it was uttered in the time of Josiah, and this is accepted by DeWette and others. To this it has been objected that the state of things described in the beginning of the book does not accord with what we know to have been the state of things in Josiah's reign, and suggests that the declaration that the calamity threatened should happen in the days of the existing generation does not tally with the assurance given by the prophetess Huldah to King Josiah, that the evil the Lord was about to bring upon Jerusalem should not happen in his day (2 Kings xxii. 15-20). Neither of these objections, however, has much weight. To the former it may be replied that, though in the later part of Josiah's reign a better state of things than that described by the prophet prevailed, in the earlier part of it things were probably exactly such as he represents, and to the latter it may be

implies that the two declarations were not inconsistent, for though the invasion of the Christians might happen in the time of the existing generation to whom the prophet spoke, it might be not till after the death of Josiah that Judaism should be taken, which in point of fact was the case. A more serious objection is that the psalm in chap. iv. could not have been composed in the early part of Josiah's reign before the reforms which he introduced had begun, and that the first and second chapters could not have been uttered after these had been inaugurated, because from the state of things then described did not exist. To meet this it has been suggested that the two parts of the book may have been composed at different times, the earlier part in the beginning and the later after the middle of the reign. This is possible, but the stand-point of the prophet is in both parts so much the same that it is not probable that any marked interval of time elapsed between the composition of the two parts, however, so ingeniously suggested with the miracle of the story of the history of the times that for aught we can tell they may have been seasons during the reign of Josiah when the good and the evil in the nation were so mixed that a prophet, whilst denouncing the wickedness he saw around him, and therefore in a way on the nation because of it, might yet be inspired by the remembrance of God's dealings with his people in the past and the hope of better things for the future, to give utterance to such a strain of adoration and exultant gladness as the hymn at the close of the book presents not in any way to doubt that the poems king and such men as Isaiah the high priest, and those associated with him as "singers of the house of God" (2 Chron. xxv. 8), would be so in sympathy with the prophet in this that they would readily approve of his psalm being consigned to "the chief singer" to be used in the temple service. An argument in favour of regarding the date of this psalm to be the reign of Josiah has been given from the names of the persons in argument and philosophy between this book and those of Jeremiah and Zechariah (cf. Hab. 1. 8 with Jer. v. 6, 13, and Zeph. in 3, Hab. 1. 13 with Jer. vi. 1, Hab. 1. 14 with Jer. xlv. 3, Hab. 1. 15 with Jer. li. 23, Hab. 1. 16 with Jer. xlv. 3, Hab. 1. 17 with Zeph. 1. 7, &c.) and in these instances Jeremiah and Zechariah have imitated Isaiah's language from him, the argument must be held conclusive in both these respects, began to prophesy in the first part of the reign of Josiah. De Wette, Hitzig, Keil, Bleek, and others assign the prophesy to the reign of Jehoiakim, but for this there seems no good reason.

(W. L. A.)

HABEAS CORPUS, in English law, is a writ issuing out of one of the superior courts, commanding the body of a prisoner to be brought before the court. There are various forms of this writ, according to the purposes for which it is intended. *This habeas corpus ad respondendum* is to bring up a prisoner confined by the process of an inferior court in order to change him with a fresh action in the court above. Other forms are *ad satisfaciendum* (when judgment has been had against a prisoner in the court below), *ad faciendum et recipiendum*, or *cum causa* (to remove the proceedings into the superior court, the defendant being under arrest), *ad testificandum* (when the prisoner is wanted as a witness), &c. These forms are now of little or no importance. The most famous form of the writ is the *habeas corpus ad subjungendum*,—the well known remedy for the violation of personal liberty. It is addressed to the person in whose custody another is detained, and commands him to bring his prisoner before the court, with a statement of the day and cause of his capture and detention,—"*ad faciendum, subjungendum, et recipiendum*, to do, submit to, and receive whatsoever the judge or courts awarding the writ may consider on that behalf." It is described as a high prerogative writ, i. e., it is one of a number of extraordinary remedies, such as *mandamus*, prohibition, and the like, which the courts may grant on proper cause being shown. The writ of *habeas corpus* issues only after motion before the court or application to a judge, made on a sworn statement of facts setting up at least a probable cause of illegal confinement. It is a common-law writ. "From the earliest records of the English law," says Hallam, "no freeman could be detained in prison except upon a criminal charge or conviction, or for a civil debt. In the former it was always in his power to demand of the Court of King's Bench a writ of *habeas corpus ad subjungendum*, directed to the person detaining him in custody, by which he was enjoined to bring up the body of the prisoner with

the warrant of commitment that the court might judge of its sufficiency and remand the party, admit him to bail, or discharge him, according to the nature of the charge. The writ issued of right, and could not be refused by the court."¹ *Habeas corpus* is, in fact, the appropriate instrument for enforcing the law of personal liberty, as declared in the Great Charter,—that no "freeman may be taken or imprisoned but by the lawful judgment of his peers or by the law of the land."

In *Daniel's case* (3 Car. I, 1627) the judges held that the command of the king was a sufficient answer to a writ of *habeas corpus*. The House of Commons thereupon passed resolutions to the contrary, and after a conference with the House of Lords the measure known as the Petition of Right was passed, which, *inter alia*, enacted that, contrary to the Great Charter and other statutes, divers of the king's subjects had been imprisoned without any cause shown, and when they were brought up on *habeas corpus*, and no cause was shown other than the special command of the king signified by the privy council, were nevertheless remanded to prison, concluded "that no freeman in any such manner as is before mentioned be imprisoned or detained." In *Jenkes's case*, 1076, the lord chancellor (Lord Nottingham) refused to issue a *habeas corpus* in the variation. Shortly afterwards was passed the famous Habeas Corpus Act (31 Chas. II. c. 2), which, *inter alia*, enacted that as a consequence of the breach of this illegal refusal of the writ in *Jenkes's case*, but which, as Hallam shows, was really due to the arbitrary proceedings of Lord Clarendon. The Act itself passed the Lords after many similar measures sent up by the Commons had been rejected.

The Habeas Corpus Act rectifies that great defect which has been used by sheriffs and jailors in making returns of writs of *habeas corpus* directed to them, and for the prevention thereof, and the more speedy relief of all persons imprisoned for criminal or supposed criminal matters, it enacts in substance as follows:—(1) When a writ of *habeas corpus* is directed to a sheriff or other person in charge of a prisoner, he must within 3, 10, or 20 days, according to the distance of the place of commitment, bring the body of his prisoner to the court, with the true cause of his detainer or imprisonment—unless the commitment was for treason or felony plainly expressed in the warrant of commitment. (2) If any person be committed for any crime—unless for treason or felony plainly expressed in the warrant—it shall be lawful for such person or persons (other than persons convicted or in execution by legal process) in time of vacation, to appeal to the lord chancellor as a judge, who shall issue a *habeas corpus* returnable immediately, and on the return thereof shall discharge the prisoner on giving security for his appearance before the proper court—unless the party so committed is detained upon a legal process or under a justice's warrant for a non-bailable offence. Persons neglecting for two terms to pray for a *habeas corpus* shall have none in vacation. (3) Persons set at large on *habeas corpus* shall not be recommitted for the same offence unless by the legal order and process of the court having cognizance of the case. (4) A person committed to prison for treason or felony shall, if he requires it, in the first week of the next term or the first day of the next session of oyer and terminer, be indicted in that term or session or else admitted to bail, unless it appears on affidavit that the witnesses for the crown are not ready, and if he is not indicted and tried in the second term or session after commitment, or if after trial he is acquitted, he shall be discharged from imprisonment. (5) No inhabitant of England (except persons contacting or coming out of England for felony, electing to be transported) shall be sent prisoner to Scotland, Ireland, Jersey, &c., or any place

¹ *Constitutional History*, vol. iii. c. 13.

beyond the seas. Stinging penalties are provided for offences against the Act. A judge delaying *habeas corpus* forfeits £500 to the party aggrieved. Illegal imprisonment beyond 40 days renders the offender liable in action by the injured party with treble costs, and damages to the extent of not less than £500, besides subjecting him to the penalties of *praemunire*, and to other disabilities. "The great rank of those who were likely to offend against this part of the statute was," says Hallam, "the cause of this unusual severity."

The Habeas Corpus Act, it will be seen, applies only to the case of person, imprisoned on criminal charges. In 1755 the question arose whether, in the case of an imprisonment for military service, a *habeas corpus* could be applied for under the Act, and other questions of some difficulty were raised as to its effect in particular cases. The judges who were consulted by the House of Lords differed in their opinions, and ultimately the Act 56 Geo. III. c. 100 was passed, "for more effectually securing the liberty of the subject." It enacts (1) that a writ of *habeas corpus* shall be issued in vacation time in favour of a person restrained of his liberty (except persons imprisoned for debt or by civil process)—a privilege granted by the Act of Charles II. only in the case of commitments for criminal offences, (2) that though the return to the writ be good and sufficient in law, the judge shall examine into the truth of the facts set forth in such return, and if they appear doubtful the person shall be bailed, (3) that the writ shall run to any harbour or road on the coast of England, although not within the body of any county. The last clause was intended to meet doubts on the applicability of *habeas corpus* in cases of illegal detention on board ship.

In Anderson's case, in 1861, the Court of Queen's Bench decided somewhat distinctly that the writ runs to all the foreign dominions of the crown even when there are independent local jurisdictions. In consequence of this decision the Act 23 and 26 Vict. c. 20 was passed, enacting that "no writ of *habeas corpus* shall issue out of England, by authority of any judge or court of justice therein, into any colony or foreign dominion of the crown where her Majesty has a lawfully established court or courts of justice, having authority to grant and issue the said writ, and to ensure the due execution thereof throughout such colony or dominion."

In times of public danger it has been found necessary to suspend the Habeas Corpus Act by a special statute. This was done in 1817 by the Act empowering the king to secure and detain such persons as his Majesty shall suspect are conspiring against his person and government. More recently this extreme measure has been judged necessary in the case of Ireland (Act 29 Vict. c. 1, continued for a short period by annual acts).

In the United States of America the law of *habeas corpus* has been inherited from England, and has been generally made to apply to commitments and detentions of all kinds. Difficult questions, unknown to English law, have arisen from the peculiar features of the American State system. Thus the constitution provides that "the privilege of the writ of *habeas corpus* shall not be suspended unless when, in cases of rebellion or invasions, the public safety may require it," and it has been the subject of much dispute whether the power of suspension under this provision is vested in the president or the congress. The weight of opinion seems to lean to the latter alternative. Again, conflicts have arisen between the courts of individual States and the courts of the Union. It seems that a State court has no right to issue a *habeas corpus* for the discharge of a person held under the authority of the Federal Government. On the other hand, the courts of the Union issue the writ only in those cases in which the power is expressly conferred on them by the constitution.

HABINGTON, WILLIAM (1605-1654), one of the most pleasing of English minor poets, was born at Hendlin in Worcestershire, on the 4th of November 1605. His father, Thomas Habington, was a prominent Catholic, to his mother, Lady Mary Habington, was attributed the revelation of the Gunpowder Plot. The poet was educated first at St Omers, and refusing to become a Jesuit was removed to Paris. On his return to England he met and fell in love with Lady Lucy Herbert, second daughter of Lord Powis, whom he celebrated under the poetical name of Custara. After some opposition he won her hand, and they were married about the year 1632. In 1634 he first published his famous volume of lyrical poems entitled *Custara*, which was reprinted in 1635 and 1649. In the latter year he also published a prose *History of King Edward VI.* and *The Queen of Arragon*, a tragic-comedy. This play was published at the request of his kinsman, the earl of Pembroke, it was afterwards revised by Samuel Butler. The last work printed by Habington was *Observations upon History*, 1641. In 1647 his father died, and during the Commonwealth, as we learn from Anthony Wood, the poet "did run with the times, and was not unknown to Oliver the usurper." He died November 30, 1654, and was buried in the family vault at Hendlin. Habington possesses all the faults of his age except his impurity, he is homophonically known as the chastest of the Royalist lyricists. His genius was gently faint yet mild in the play of fancy, delicately ingenious, and of an unforced stately dignity. He never rises to sublimity or passion, but he is always gentlemanlike and often extremely graceful. His best voice, have a very modern tone, and would read the reader of the 18th rather than of the 17th century.

The works of Habington have not been collected. An edition of *Custara* was published by Mr. Ainslie in 1870, and *The Queen of Arragon* has been included in the Dodsley collection.

HACHETTE, JEAN NICOLAS PIERRE (1760-1831), an eminent French mathematician, was born at Mézières, where his father was a bookseller, on the 6th May 1769. For his early education he proceeded first to the college of Charleville, and afterwards to that of Rheims. In 1788 he returned to Mézières, where he was attached to the school of engineering as draughtsman to the professors of physics and chemistry. When twenty-three years of age he succeeded from among a number of candidates in gaining the professorship of hydrography at Collioure and Port-Vendres. While there he sent several able papers, in which some questions of navigation were treated geometrically, to Monge, at that time minister of marine, through whose influence he obtained an appointment in Paris. Thence he passed to a deputy-professorship at Mézières, and towards the close of 1794, when the Ecole Polytechnique was established, he was chosen one of its staff, being appointed along with Monge over the department of descriptive geometry. There he instructed some of the ablest Frenchmen of the day, among them Poisson, Ampère, and Fresnel. Accompanying Guyton de Morsve in his expedition, earlier in the year, he was present at the battle of Fleurus, and entered Brussels with the French army. In 1816, on the accession of Louis XVIII., he was expelled from his chair by Government, at the same time that his friend and fellow-worker Monge was removed from the Institute. He retained, however, till his death, the office of professor in the faculty of sciences in the Ecole Normale, to which he had been appointed in 1810—the same year in which he married the daughter of the physician Mawgias. The necessary royal assent was in 1823 refused to the election of Hachette to the Academy of Sciences, and it was not till 1831, after the Revolution, that he obtained that well-merited honour. He died at Paris, January 16, 1834. Hachette was held in high esteem for his private worth, as

well as for his scientific attainments, and great public services. His labours were chiefly in the field of descriptive geometry, with its application to the arts and mechanical engineering. It was left to him to develop the geometry of Monge, and to him also is due in great measure the rapid advancement which France made soon after the establishment of the École Polytechnique in the construction of machinery. His writings on descriptive geometry are still of value.

His chief principal works are his *Deux Suppléments à la Géométrie Descriptive de Monge*, 1811 and 1818, *Éléments de Géométrie à trois dimensions*, 1817, *Collection des Figures de Géométrie*, &c., 1795 and 1817, *Applications de la Géométrie Descriptive*, 1817, *Traité de Géométrie Descriptive*, &c., 1823, *Traité Élémentaire des Machines*, 1811, *Correspondance sur l'École Polytechnique*, 1804-1815. He also contributed many valuable papers to the leading scientific journals of his time.

HACHETE, LOUIS CHRISTOPHE, FRANÇOIS (1800-1861), a French publisher, was born at Bethel in the Ardennes, May 5, 1800. After studying three years at a normal school with the view of becoming a teacher, he was in 1823 on political grounds expelled from the seminary. He then devoted several years to the study of jurisprudence, but in 1826 he resolved to establish in Paris a publishing business, the main object of which should be the issue of works adapted to improve the system of school instruction, or to promote the general culture of the community. The series of works which from that time were brought out by him included manuals in various departments of knowledge, dictionaries of modern and ancient languages, educational journals, and French, Latin, and Greek classics annotated with great care by the most eminent authorities. Subsequent to 1850 he, in conjunction with other partners, published a cheap railway library, scientific and miscellaneous libraries, an illustrated library for the young, libraries of ancient literature, of modern foreign literature, and of modern foreign romances, a series of guide-books, and a series of dictionaries of universal reference. In 1855 he also founded *Le Journal pour tous*, a publication with a circulation of 150,000 weekly. There can be no question that by his efforts to circulate such a variety of wholesome and instructive literature, Hachette is entitled to rank among the greatest benefactors of his country. He also manifested great interest in the formation of mutual friendly societies among the working classes, in the establishment of benevolent institutions, and in other questions relating to the amelioration of the poor, on which subjects he wrote various pamphlets, and he lent the weight of his influence towards a just settlement of the question of international literary copyright. He died 31st July 1861.

HACKBERRY, a name given to the fruit of the *Celtis occidentalis*, L., belonging to the natural order *Umbelliferae*. It is also known under the name of "sugar berry," "beaver-wood," and "nettle tree." The hackberry tree is of middle size, attaining from 60 to 80 feet in height, and with the aspect of an elm. The leaves are ovate, cordate ovate, and ovate lanceolate, with a very long taper point,—mostly glabrous above, and usually soft-pubescent beneath. The soft filmy flowers appear early in the spring before the expansion of the leaves. The fruit is berry, about the size of a bud cherry, is of an obovate shape, of a reddish or yellowish colour when young, turning to a dark purple in autumn. This tree, together with other species of the same genus, is distributed through the deep shady forests bordering the river banks of New England to Wisconsin and even farther southward. The fruit has a sweetish and slightly astringent taste, and is largely eaten in the United States, and, although not official, has been highly recommended in cases of dysentery. The seeds contain an oil like that of almonds. The bark is tough and fibrous like

hemp, the wood is hard and compact and heavy, and next to ebony and box has been spoken of as the best for durability, strength, and beauty, its tenacity and flexibility have led to its employment as shafts for carriages, hoops, &c. The root has been used as a dye for linens. The root, bark, and leaves of *C. occidentalis* are employed in the East as a remedy in epilepsy.

HACO, or HAKON (c. 920-960), surnamed the Good, king of Norway, was the son of Harold Fairhair by a female slave, and was presented by Harold to king Athelstan of England, to mark his contempt for an insult he had received. The child was placed by a Norse wassailor on Athelstan's knee, who thus made to observe the symbol of adopting a child that was born Athelstan did not, however, take vengeance on the innocent cause of his anger, but brought him up as one of his own sons. On hearing of the death of Harold, he supplied Haco with men and ships, and sent him to Norway to wrest the throne from Eric, eldest son of Harold, whose violent and cruel reign had during the life of his father gained him the general hatred of his subjects. The news of Haco's arrival in Norway spread says the saga, "hko flic thoghen dind grass." Eric at once took flight to Orkney and then to England, and Haco was chosen king at every "thing." Haco, though himself a Christian, found it impossible in his time to establish Christianity in Norway. He was a king who with great justice and prudence, and gained for his many victories over the Danes by land and sea. He was slain in a great fight against the Danes, led by the sons of Eric, about the year 960.

HACO V, surnamed the Old, king of Norway, son of Haco IV, was on the death of his father in 1204 excluded from the throne on the ground of supposed illegitimacy, and only became king in 1223, after his mother, to establish his rights, had undergone the ordeal of fire. He greatly increased the prosperity of Norway, and he also added to his kingdom Iceland and Greenland. As he had a dispute with Alexander III. of Scotland in regard to the sovereignty of the Hebrides, he set sail about 1263 on a great expedition against the west of Scotland, where he took possession of Ailan and Bute, but suffered such a severe defeat at Largs that he was compelled again to put to sea. After losing many ships by storm, he sailed to Orkney, where he died in the following winter. It is supposed by some that his fleet in his voyage north passed between Skye and the mainland, and that it is from this fact that the narrow sound of Kyle-Akin received its name.

For the kings named Haco see the *Hemetsingla* of Snorro Sturluson, which, however, does not include the reign of Haco V, translated into English by Samuel Laing, London, 1814. The saga of Sweave and his successors was published by Unger under the title *Konunga Sögur*, Göttingen, 1810-73. The *Saga of Hakonar Hakonarson* forms the 10th vol. of the *Formannna Sögur* published at Copenhagen in 12 vols., 1825-39, and translated into Danish and Latin in 12 vols., 1828-40. See also *Sturlunga Saga*, 2 vols., Oxford, 1878, and Odlly's *Earl Kings of Norway*, London, 1875.

HADAD, the name of a Syrian deity, is met with in Scripture as the name of several human persons, it also occurs in the compounds Benhadad, Hadadimmon, and Hadadesser. The etymology of the word, of which Hadat, Ader, and Arad appear to be incorrect variations, is obscure, the divinity primarily denoted by it, however, according to Philo of Byblos (Müller, *Ph. Hist. Gr.*, iii. 569, cf. Manab, *Saturn.*, i. 23), is the king of the gods, the greatest and highest, the sun, and these interpretations seem to point to some such radical meaning as *unus*. The Syrian kings of Damascus seem to have habitually assumed the title of Benhadad, or son of Hadad (three of this name are mentioned in Scripture), just as a series of Egyptian monarchs are known to have been accustomed to call themselves sons of Ammon-Ra. The word Hadadimmon,

for which the inferior reading Hadadimmon is found in some MSS, in the phrase "the mourning of (or at) Hadadimmon" (Zech xii 11), has been a subject of much discussion. According to Jerome and all the older Christian interpreters, the mourning for what occurred at a place called Hadadimmon (Mactinapolis) in the valley of Magdalo is meant, the event alleged to be generally held to be the death of Josiah, but since Hitzig and Movers the opinion has been gaining ground that Hadadimmon is merely another name for Adonis or Thammuz, the autumn sun-god, the allusion being to the mourning, by which the Adonis festivals were usually accompanied (Hitzig on Zech xii 11, Isa xvi 8, Movers, *Phœnicie*, i 196).

Full citations for the whole discussion will be found in Druce and Sturtevant's *Sam. Religionsgesch.* (1878), Abh. v. The author, however, has considerably modified his views in Herzog and Plitt's *R. B. s. t.*, having in his earlier essay been misled in important points by statements of Schrader (*Kleinere Schrift. A. T.*, pp. 101 seq.), which have since been found to require correction (see Gutschmidt, *Neue Beiträge*, p. 17 seq., Wellhausen's criticism of Druce in *Zeit. f. d. Alt. Ori.* (1877), Str. 6, Schrader, *Keiten und Gesch. d. Israel* (1878), pp. 371 seq., 638 seq.).

HADDINGTON, or **EAST LOTHIAN**, a maritime county of Scotland, lies between 55° 40' 10" and 56° 4' N. lat. and between 2° 5' and 2° 40' W. long. It is bounded on the N. by the Firth of Forth, on the E. by the North Sea, on the S. by Berwickshire, on the W. by Edinburghshire. Its seaboard is 31½ miles. Its greatest length from east to west is 25 miles; its breadth from north to south about 16 miles. Its area covers 170,112 acres (280 square miles), of which 189½ are under water, 5505 foreshore, and 142½ in "links." The general outline of the county is that of an irregular quadrilateral figure with its northern angle projecting into the sea. Along a south-and-north line through the county town, the land slopes gradually up from the coast to the Gullaton Hills, thence down to the Tyne valley, and then up again to the Lammermuir Hills, which occupy the southern district of the county. On the east and west the ground slopes from the Lammermuir to the sea, but near the sea the fall is so gentle that the land has the appearance of a plain. Two almost isolated hills break the level,—North Berwick Law (612 feet) on the coast, and Traprain Law (724) in the eastern part of the Tyne valley. The chief summits of the Lammermuir Hills are Sparleton (1534), Lamme Law (1500), and South Uill (1280). The only stream of any importance is the Tyne, which, after a course of 7 miles in Midlothian, flows through the county with a gentle current north-east past the town of Haddington, and falls into the sea at Tyne-mouth. A very fine variety of trout is found in it, and below the rocks of the linn at East Linton salmon are occasionally caught. The Whittender rises in the county, and flows south-east into Berwick.

Geology and Mineralogy.—The Lammermuirs are composed chiefly of Lower Silurian shales, overlaid in part by Old Red Sandstone and conglomerate—one great mass of the latter extending south-east from Spott, with a breadth of 3 or 4 miles, across the hills into Berwickshire. Another belt of Old Red Sandstone, rather more than 1 mile in breadth begins at the sea a little to the south of Dunbar, and stretches along the base of the Lammermuir. Patches of Old Red Conglomerate occur also here and there in the Lammermuir further to the west, and are seen in the upper tributaries of Gifford and Humble waters. The ground to the north of the Lammermuir is occupied chiefly by rocks belonging to the Calciferous Sandstone and Carboniferous Limestone series of the Carboniferous formation. The Calciferous Sandstones cover a wide area west and east of Haddington, extending south to the Lammermuir, along the base of which they trend south-west beyond the county boundary. They also appear in the lower reaches of the

Tyne valley, covering a considerable area between Tynninghame Links and Bell Busk. Again, they are seen on the shore between Tynes Point and Douglas Burn, whence they strike inland. The hilly tract between Haddington and North Berwick is made up of various volcanic rocks of Lower Carboniferous age, such as porphyry, dolerite, and tuff. In the western part of the county the Carboniferous Limestone series occupies an extensive area and is rich in limestones and coal seams. This area forms the eastern margin of the Midlothian coal-field. A patch of the Limestone series also appears upon the coast about a mile south of Dunbar. Besides these bedded aqueous and volcanic rocks, there are numerous intruded masses, dykes, and veins of dolerite and basalt, and some pieces of tuff and agglomerate which mark the sites of ancient volcanoes of Lower Carboniferous age. Granite is found at Priestlaw. Deposits of glacial origin are met with more or less abundantly, especially in the low lying tracts. These consist of till or boulder-clay and mounds and sheets of sand and gravel, underneath which the older rocks are often concealed over wide areas. Alluvial deposits occur along the course of many streams, but the only considerable alluvial flats are those of the Tyne.

Coal.—It is of a very fine quality, and extensively worked in the west. So long ago as 1200 the monks of Newbattle obtained this mineral from Pictongrange. Limestone is found throughout the greater part of the shire. A vein of hematite of a peculiarly fine character was discovered in 1866 at the Gullaton Hills, and wrought for some years, but from a variety of causes the works have been many times suspended.

Climate.—The climate is on the whole mild and equable. East winds, however, prevail in the months of March, April, and May, and from the north of the county it is experienced that the amount of rainfall is far below the average of Great Britain. During the period 1835–64 the average annual rainfall was 24.85 inches,—the greatest fall being 32.7 in 1850, the least 17.8 in 1843. The average monthly fall is lowest in April (1.16) and highest in August (2.57). In 1872 the rainfall reached the exceptional amount of 41.51 inches.

Agriculture, &c.—The soils are various. The Lammermuir are of course unproductive, but the slopes to a considerable height are cultivated, and for a considerable way down the land is very good. In the centre of the county there is "a tenebrous yellow clay resting upon a silty subsoil," and this land is not well suited for agricultural purposes. Along the margin of the Firth the soil is naturally of a sandy nature, but farther inland it is composed of rich loam and is very fertile. The most productive regions are the land about Dunbar. The principal crops are very good, and the soil is very fertile. The soil is so highly esteemed in the London market, selling at times for as much as £45 an acre. From the beginning of the present century till within the past few years East Lothian agriculture has on the whole been held to be the best in Scotland. This is not so much due to the natural fertility of the soil as to the enlightened enterprise of its cultivators. Andrew Menzie here first introduced the threshing mill (1767). This farming was first extensively used here, and the reaping machine (now universally employed) and the steam plough were introduced at comparatively early periods of their history. The high price of grain at the time of the Crimean War gave a great impetus to farming, and in consequence rents rose as much as from 15s. to £1. per acre, thus, with the increased cost of labour, which has risen 35 to 40 per cent. (about 10s. per acre) within the last seven or eight years, he sadly diminished the profits of the farmer. The cost of crops has also risen, wheat, for instance, from 15s. 6d. to 16s. 7d. The majority are from 300 to 500 acres—a very few from 600 to 1200 acres. They are usually let on leases of nineteen years' duration. The rotation of crops is generally the six course shift, viz. (1) grass (pasture or hay), (2) oats, (3) potatoes, turnips, or beans, (4) wheat, (5) turnips, (6) barley.

According to the agricultural returns of 1879, of the total area of 179,142 acres 115,854 were under cultivation, distributed as follows:—corn crops, 44,719 (wheat, 7910, barley, 15,628, oats, 15,746), green crops, 25,656 (potatoes, 9885, turnips and swedes, 14,769), clover and grass, 27,194, permanent pasture, 18,000, bare fallow, 1075. Of live stock the numbers were:—

¹ See the *Geology of East Lothian*, by Howie, Geikie, and Young, with Appendix on Fossils, by G. W. Saltir. Other works are enumerated on p. 68 of this treatise.

them he saw that the period of conquest was past, that an extension of the frontiers would only weaken the defensive power of the empire, that the time for consolidation and for softening the distinction between Rome and the provinces was come. While Trajan had been guilty of the anachronism of rivaling Alexander the Great, Hadrian made it the work of his life to become acquainted with the provinces, to learn their needs and resources, to improve and benefit them, he sought to be the effective ruler of the empire as a whole, and so was the first to realize the cosmopolitan task which his position imposed. For this end he sought to obtain a personal knowledge of the people he had undertaken to govern. Leaving Rome in 118, he visited probably every province of the empire. After traversing Gaul he inspected the legions on the Rhine, and then crossed to Britain, where he built (121) the great rampart from the Tyne to the Solway which bears his name. He returned through Gaul into Spain, and then proceeded to Mauritania, where he suppressed an insurrection. We next find him in the East averting a war with Parthia by a timely interview with the king. From the Parthian frontier he travelled through Asia Minor and the islands to Athens, where he sojourned a considerable time, and so returned by Sicily to Rome, having made the circuit of the empire. After some stay at Rome he resumed his travels. It is impossible to fix the details of this second progress with any exactness. It was chiefly in the East, and he did not finally return to Rome till 131. Everywhere he left lasting traces of his restless and beneficent energy, he built aqueducts and temples, and raised fortifications in suitable places, he inspected the details of the administration, learned to know the officials, and made himself at home in the military encampments. He was accompanied by a body of architects and citizens organized like a legion, whom he employed to gratify his passion for building in a truly imperial manner. Athens was the favoured scene of his architectural labours, he added a new quarter to the city, and finished the temple of the Olympian Zeus. While Hadrian spent his life in inspecting the provinces, and was not disinclined to purchase peace by a subsidy to the restless tribes on the frontiers, he did not neglect the army. All along the frontier his legions stood in constant preparation for battle. He maintained a rigorous discipline, the rules he drew up for the army long served as a kind of military code. He trained them to the severest exercises, and anticipated all complaint by sharing in their fatigues, walking bare-headed on a march of 20 miles a day, and partaking of their coarse fare of cheese, lard, and sour wine. The only important war in which this army was tested was the great rebellion of the Jews, which broke out in 131, and lasted for several years. The founding of a Roman colony on the site of Jerusalem, and an order of Hadrian forbidding the rite of circumcision, were the causes of the war. The Jews fought with the most resolute despair, and they were crushed only by a powerful army commanded by the best general of the empire. According to Dion, 880,000 Jews fell in battle. The whole country was reduced to a wilderness. But the loss of the Roman legions was so severe that in writing to the senate Hadrian omitted the customary formula—"If you and your children are well, it is well, I and the army are well." In the later years of his life Hadrian discerned his end, and lived at Rome or near it. His health, which had been impaired by long exposure to the extremes of heat and cold, began to fail, and, what was worse, the dark and suspicious moods which had broken out occasionally in his earlier years became more frequent and fatal. His aged brother-in-law Servianus fell a victim to his jealousy, his wife Sabina died, not without a rumour of poisoning. Most of those who had been his familiar

friends, and had been raised by him to the highest offices, were superseded, or banished, or put to death. But his passion for architecture did not abate. He built for his residence the great villa of Tibur, which was eight miles in circuit, and was a kind of epitome of the world, with miniatures of the most celebrated places in the provinces, and even of Hades. He built a splendid mausoleum, which has been the nucleus of the castle of St Angelo, and rebuilt several edifices at Rome. In these years he had to choose a successor. His first choice was Ælius Verus, who did nothing to justify such a distinction. The next was Antoninus Pius, so called from the final assentivity with which he cherished the last days and the memory of his adopted father. Antoninus saved him from suicide, to which his physical sufferings impelled him, and from imbruing his hands in the blood of many noble Romans, who had provoked his moody and fickle temper. Hadrian died at Bæta, 138 A.D. The cruelty of his latter life had so eclipsed the lustre of his early rule that the senate at first refused him divine honours, and were prevailed upon to grant them only at the urgent solicitation of Antoninus. In the travels and administrative energy of Hadrian we see only one side of his character. He had a versatile and many-sided mind, in which the faculty for command, speculative curiosity, and literary ambition were strangely blended. Not satisfied with the title imposed on the laborious autocrat of the world, he sought to excel the Greek professors and artists each in his own special walk. In painting, sculpture, and music, in rhetoric and philosophy, he considered himself the competent rival and critic of men who had made these pursuits the work of a lifetime. The architect Apollodorus atoned for his frankness with his life. The more politic Favonius, when reproached for yielding too readily to the emperor in some grammatical discussion, replied that it was unwise to dispute with the master of thirty legions. The product of Hadrian's pen which has been most celebrated is the dying address to his soul—

"Annua vagula, blandula,
Hepes, comique corporis,
Quæ nunc abitis in loca
Fulidula, rigula, munda."
Nunc, ut solis, abis, puer?"

Under Hadrian Salvius Julianus composed a "perpetual edict," which is supposed to have been a fixed code of some kind, but the exact significance of the edict is disputed. Still there can be no doubt that Roman law owes much to Hadrian.

The sources for Hadrian's life are unsatisfactory, the chief are Spartianus in the *Spartianus Historia Augusta*, and Dion Cassius as charged by Xiphonius, lib. lxxv, see also Ammianus Marcellinus, *De Caesaribus*, and Eutropius, for modern works consult *Marx's History of the Romans under the Empire*, *Oriental History*, and *W. W. Capes's "Age of the Antonines"* in the series *Epochs of Ancient History*. (F. K.)

HADRIAN, WALL, or It is under this heading that it seems most convenient to give a short account of the stone wall and other works erected by the Romans in the north of England between the Solway and the Tyne, and commonly known as the Roman Wall. As will be afterwards seen, those who have written on the subject are by no means agreed that the name of Hadrian ought to be exclusively associated with this great fortification. But before touching on the question, it is necessary to describe the works themselves.

Viewed as a whole the Roman Wall, when entire, consisted of three parts—(1) a stone wall, strengthened by a ditch or fosse, at a short distance from its northern base, (2) three parallel earthen walls, with a ditch sloping down from the northern side of the second of these lines, (3) stations, castles, and turrets, placed at various intervals for the accommodation of troops, and communicating with one another by a military way.

as from sitting on the wet ground. Piles are only a symptom, and in their treatment this should be kept in view, to remove the cause and the piles will disappear. The local treatment is palliative or radical. The palliative treatment consists in attention to the state of bowels, cold bathing, astringent injections, lotions, and ointments. The radical treatment consists in their removal, the external pile is cut off, the internal pile is tied or clamped and cauterized. Both methods have their advocates, the radical treatment should not be undertaken until palliative treatment has failed. When in a state of inflammation the treatment consists in hip baths, hot fomentations, and poultices. The introduction of a morphia suppository often relieves the uneasiness. Both varieties are often met with in the same individual, when this is the case both should be removed by operation at one time. The internal piles are apt to return if the proctopositing cause is still in existence. Piles are apt to be confounded with other surgical diseases in this region, as fissure or ulcer, prolapse, polypus, or cancer. This is not the place to point out the distinguishing features of these different maladies, the patient should consult a surgeon. There is a form of piles situated just at the verge of the anus, where the skin joins the mucous membrane, its onset is sudden, and due to the rupture of a blood-vessel, the blood is extravasated and clots, a small, tense, painful swelling of a bluish colour is seen at the edge of the anus. This may be relieved by hot fomentations, or the pile may be laid open and the clot turned out by gentle pressure.

HAFIZ Muhammad Shamsuddin, better known by his *takhtul* or "nom de plume" of Hafiz, was one of the most celebrated writers of Persian lyrical poetry. He was born at Shiraz, the capital of Fars, in the early part of the 8th century of the Mahometan era, that is to say, in the 14th of our own. The exact date of his birth is uncertain, but he is known to have attained a ripe old age and to have died in 791 A.H. (1388 A.D.). This is the date given in the chronogram which is engraved on his tomb, although several Persian biographies give a different year. Very little is actually known about his life, which appears to have been passed in quiet retirement and literary ease in his native city of Shiraz, of which he always speaks in terms of affectionate admiration. He was a subject of the Muzaffari pinnos, who ruled in Shiraz, Yazd, Kerman, and Isfahan, until the dynasty was overthrown by Timur lang (Tamerlane). Of these pinnos his especial patrons were Shah Shiq'ah and Shah Mansur. He early devoted himself to the study of poetry and theology, and also became learned in mystic philosophy, which he studied under Shaikh Mahmud 'Adh'ir, chief of an order of dervishes. Hafiz afterwards enrolled himself in the same order and became a professor of Koranic exegesis in a college which his friend and patron Hafiz Kiwam uddin, the *Wazir*, specially founded for him. This was probably the reason of his adopting the *sobriquet* of Hafiz, which means "one who remembers," and is technically applied to any person who has learned the Koran by heart. The restraints of an ascetic life seem to have been very little to Hafiz's taste, and his loose conduct and wine bibbing propensities drew upon him the severe censure of his monastic colleagues. In revenge he satirizes them unmercifully in his verses, and seldom loses an opportunity of alluding to their hypocrisy and religious pretensions. Hafiz's fame as a poet was soon rapidly spread throughout the Mahometan world, and several powerful monarchs sent him presents and pressing invitations to visit them. Amongst others he was invited by Mahmud Shah Bahmani, who reigned in the south of India, and set off with the intention of sojourning at the court of that sovereign. After crossing the Indus and passing through Lahore he reached Humna, and embarked on board a

vessel sent for him by the Indian pinnos. He seems, however, to have been a bad sailor, and, having invented an excuse for being put ashore, made the best of his way back to Shiraz. Some biographies narrate a story of an interview between Hafiz and the invader Timur. The latter sent for him and asked angrily, "Art thou he who was so bold as to offer my two great cities Samarcand and Bokhara for the black mole on thy mistress's cheek," alluding to a well known verse in one of his odes. "Yes, sire," replied Hafiz, "and it is by such acts of generosity that I have brought myself to such a state of destitution that I have now to solicit your bounty." Timur was so pleased at the ready wit displayed in this answer that he dismissed the poet with a handsome present. Unfortunately for the truth of this story Timur did not capture Shiraz till 1393 A.D., while the latest date that can be assigned to Hafiz's death is 1391. Of his private life little or nothing is known. One of his poems is said to record the death of his wife, another that of a favourite unmarried son, and several others speak of his love for a girl called *Shah'ah Nabal*, "Sugar-cane branch," and this is almost all of his personal history that can be gathered from his writings. He was, like most Persians, a Shiah by religion, believing in the transmission of the office of Imam, or head of the Muslim Church in the family of Ali, cousin of the prophet, and respecting the *Hadiths*, or traditional sayings of Mahomet, which form the Sunnah, or supplementary code of Mahometan ceremonial law. One of his odes which contains a verse in praise of Ali is engraved on the poet's tomb, but is omitted by Sadi, the Turkish editor and commentator, who was himself a rigid Sunni. The same sectarian bigotry has influenced many other editors, and it is no unusual thing to find an Indian edition of the *Diwan* emasculated by the excision of all the passages which can be construed as having the slightest allusion to the objects of Shiah veneration. That his tendencies were towards a rather extravagant and haeetical form of theosophy may be deduced from his writings, and in one verse he even goes so far as to speak in terms of admiration of one Mansur of Halka who was hanged, after being put to the most horrible tortures, on a charge of blasphemy, 809 A.H. This person professed a creed nearly approaching pure pantheism, and went about asserting that he was himself an incarnation of the omnipotent divinity, saying, *Ana 'Ullah*, "I am the Truth!" Hafiz in allusion to this says that his only fault was that he revealed the mystery. These haeetical opinions and the dissipated life of the poet caused difficulties to be raised by the ecclesiastical authorities on his death as to his interment in consecrated ground. The question was at length settled by Hafiz's own works, which had then already begun to be used as they are now throughout the East for the purposes of divination, in the same manner as *Vergil* was employed in the Middle Ages for the divination called *Sortes Vergilianae*. Opening the book at random after pronouncing the customary formula asking for inspiration, the objectors hit upon the following verse—"Turn not away thy foot from the Bier of Hafiz, for though immersed in sin, he will be admitted into Paradise." He was accordingly buried in the centre of a small cemetery at Shiraz, now included in an enclosure called the *Hafiziyeh*.

His principal work is the *Diwan*, that is, a collection of short odes or sonnets called *ghazals*, and consisting of from five to sixteen *bars* or couplets each, all the couplets in each ode having the same rhyme in the last hemistich, and the last couplet always introducing the poet's own *nom de plume*. The whole of these are arranged in alphabetical order, an arrangement which certainly facilitates reference but makes it absolutely impossible to ascertain their chronological order, and therefore deteriorates from their value as a means of throwing light upon the growth and develop-

ever, is now long past. His learning and his style have been eclipsed by later and greater poets, and he who was at one time the "allgemeine Bewunderung von Deutschland" now ranks only among the secondary German classics.

The first collection of Hagenedor's poems was published at Hammung shortly after his return from Jura in 1729, under the title *Verisch einiger Gedichte, oder vielmehr Proben poetischer Können*. In 1738 appeared *Verisch in poetischen Reden, und Betrachtungen*, in 1747 a collection of his lyric poems, under the title *Sammlung neuer Oden und Lieder, und in Abtheilung Gedichte* in 1760. A collection of his entire works was published at Hammung after his death in 1766, and a smaller edition in 1767. The best is Knechteling's edition, 6 vols., 1800, republished, with Hagenedor's correspondence, in 1826. See H. O. Schmidt, *Biographie von Hagenedor*.

HAGEN, a town of Prussia, at the head of a circle in the Arnsberg government of Westphalia, is situated at the confluence of the Empe with the Volme, and at the junction of several railways, 26 miles W S W from Arnsberg. It is the seat of a provincial office, a circle court, a chamber of commerce, a state railway commission, and an agricultural union. It has two Evangelical churches, a Catholic church, an Old Catholic church, a synagogue, a real school of the first order, a royal provincial trade school, a higher female school, and two infirmaries. Hagenedor is one of the most flourishing commercial towns in Westphalia, and possesses puddling works for iron and steel, iron foundries, cast steel works, a large cotton print work, woollen and cotton factories, manufactures of leather, paper, tobacco, and iron and steel wares, breweries, and distilleries. There are large limestone quarries in the vicinity, and also an alabaster quarry. The population in 1875 was 24,335, or including Althagen 26,870.

HAGEN, FRIEDRICH HEINRICH VON DER (1780-1856), distinguished for his researches in Old German literature, was born at Schmiedeberg in Brandenburg, 19th February 1780. After studying law at the university of Halle, he obtained a legal appointment in the state service at Berlin, but in 1806 he resigned this office in order to devote himself exclusively to the study of his chosen field. In 1810 he was appointed professor extraordinarius of German language and literature in the university of Berlin, in the following year was transferred to a similar professorship in Breslau, and in 1821 returned to Berlin as professor ordinarius. He died at Berlin, 11th June 1856. To Hagenedor belongs the chief merit of awakening an interest in Old German poetry, of which he published several collections.

His principal publications are the *Nibelungenlied*, of which he issued four editions, the first in 1810 and the last in 1848, the *Minnesagen*, Leipzig, 1838-52, 6 vols., *Lieder der älteren Dichter*, Berlin, 1812, *Altdeutsche Lieder und Sagen*, Breslau, 1814, a collection of Old German tales under the title *Gesammlte altdeutsche Sagen*, 1810, 8 vols. He also published *Über die altdeutsche Dichtkunst des Mittelalters*, Berlin, 1844, and from 1855 he edited the *Zeitung der Deutschen Gesellschaft für deutsche Sprache und Alterthumskunde*.

HAGENAU, the chief town of a circle and canton in Alsace Lorraine, Germany, district of Lower Alsace, is situated in the middle of the Haguenau Forest, on the Moselle, and on the railway from Sursburg to Weissenburg, 10 miles N N E of the former town. It has two ancient Catholic churches, one dating from the 12th of the other from the 13th century, a gymnasium, a reformatory for boys, a female penitentiary, a public library, a hospital, and a theatre. The principal industries are wool and cotton spinning, and the manufacture of porcelain, earthenware, soap, leather, oil, and beer. There is also considerable trade in hops, vegetables, and wine. Population (1875), 11,786.

Hagenau dates from the beginning of the 12th century, and owes its origin to the erection of a hunting lodge by the dukes of Swabia. Frederick Barbarossa surrounded it with walls and gave it a castle. On the site of the hunting lodge he founded an imperial palace, in which were preserved the jewelled imperial crown, sceptre, imperial globe, and sword of Charlemagne. Subsequently

the town obtained imperial rights, and after the extinction of the Hohenstaufers it remained the capital of the bailiwick of Lower Alsace. In 1618 it came into the possession of France, and in 1673 Louis XIV. caused the fortifications to be raised. In 1676 it was captured by imperial troops, but in 1677 it was retaken by the French and nearly all destroyed by fire. In 1871 it came along with the rest of Alsace Lorraine into the possession of France.

HAGENBACH, KARL RUDOLF (1801-1874), destined as a church historian and as an expounder of the so-called "Vermittelungstheologie," or mediation theology of Germany, was born March 4, 1801, at Basel, where his father, a man of considerable talent and scientific reputation, was a practicing physician. His preliminary education was received at a Pestalozzian school, and afterwards at the gymnasium, whence in due course he passed to the newly reorganized local university. Carefully brought up within a church in which the strictest orthodoxy still continued to hold undisputed sway, familiar at the same time from boyhood with his father's expressions of approval of the principles of the French Revolution, himself of an ardent, sympathetic, inquiring, and devout temperament, he early devoted himself to theological studies and to the service of the church, while at the same time cherishing and developing broad "humanistic" tendencies which found expression in many ways and especially in an extensive acquaintance with the writings of Herder. The years 1820-23 were spent first at Bonn, where Lucke exerted a powerful influence on the formation of his opinions, and afterwards at Berlin, where Schleiermacher, and still more Neander, became permanently his masters. Returning in 1823 to Basel, where Dr Wette had recently been appointed to a theological chair, he distinguished himself greatly by his "habilitationsschrift" or trial dissertation, entitled *Über rationes historico-metaphysicae circa Originis methodum inter pretares sacrae Scripturae*, &c., in the following year he became professor extraordinarius, and in 1829 professor ordinarius of systematic theology. Apart from his special academic labours during many years in connexion with the history of dogma and of the church (which first owed to him their recognition as distinct branches of study at Basel), he lived a life of great and varied usefulness as a theologian, a preacher, and a citizen, and at his "jubilee" in 1875, not only the university and town of Basel but also the various churches of Switzerland united to do him honour. He died at Basel, June 7, 1874.

Hagenbach was a voluminous author in many departments (as will be seen from the list of his works which is given below), but it is as a writer on church history that he is most influential and is likely to be longest and most widely known. Though neither so learned and profound as the contributions of Gieseler, nor so original and profound as those of Ritschl, his lectures are written with remarkable clearness and strictness, and are justly appreciated at once for their warm glow of sympathy with his subject and for their entire freedom from minor sectarian prejudices. In dogmatics, while everready a champion of the "mediation theology" based upon the fundamental conceptions of Herder and Schleiermacher, he was much less obstinate in his aims and in his results than were many others of his school. To the last he sought to maintain the old confessional documents, and to maintain objective and churchly peace over the purely subjective manner of viewing theological questions. But he himself was aware that in the endeavor to do so he was not always successful, and that his deductions of Christian dogma often left a feeling of weakness and uncertainty behind. His works include a remarkably clear *Tabellen über Vertheilung des Dogmengeschichts* (1828), *Enzyklopädie u. Methodologie des Theol. Wissenschaften* (1833), *Verlesungen über Wesen u. Geschichte der Reformation u. des Protestantismus* (1834-43), *Lehrbuch des Dogmengeschichts* (1840-41, 6th ed. 1867, English transl. 1850), *Verlesungen über die Geschichte der alten Kirche* (1833-55), *Verlesungen über die Kirchengeschichte des Mittelalters* (1850-61), *Geschichte der Theologie u. Literatur* (1863), a bibliography of Ecolampadius and Myconius and a *Geschichte der theol. Schule Basels* (1860). His *Prolegomena* have been published in three volumes (1866-76), and he is also author of two volumes of *Verlesungen über die Kirchengeschichte des Mittelalters* (1866-76), and *Geschichte* (1866-76). The lectures on church history under the general title *Verlesungen über die Kirchengeschichte vom alten Atest bis zum 19ten Jahrhundert* have been recently issued in seven volumes (1868-72).

HAGERSTOWN, a city and township of Maryland, United States, capital of Washington county, is situated near the west bank of Annapolis creek, 20 miles from its confluence with the Potomac river, and at the junction point of three railways, 86 miles W N W by rail from Baltimore. It is a well-built town with very few wooden houses, and possesses a fine new court-house, a male and a female academy, and a national and a state bank. It depends for its prosperity chiefly on agriculture, and has flour mills, bone-mills, machine shops, and a tannery, and considerable trade in agricultural produce. The population in 1860 was 3831, in 1860, 4132, and in 1870, 5779, of whom 869 were coloured.

HAG-FISH, GLUTINOUS HAG, or DOBZ (Haguse), a marine fish which forms with the lampreys one of the lowest orders of vertebrates (*Cyclostomata*). Similar in form to a lamprey, it is usually found within the body of dead cod or haddock, on the flesh of which it feeds after having buried itself in the abdomen. When caught, it secretes a thick glutinous slime in such quantity that it is commonly believed to have the power of converting water into glue. It is occasionally found in the North Atlantic and other temperate seas of the globe.

HAGGAI, the tenth in order of the minor prophets. The name Haggai (חגאי, Greek Ἀγγαιο, whence Aggeus in the English version of the Apocrypha) is usually held to be an adjective meaning *festive*. But Wellhausen¹ is probably right in taking the word as a contraction for Hagaiiah (*Haghaiah, hath, gaidel*), just as Zaccai (Zacharias) is known to be a contraction of Zechariah (*Zech, Derenbourg, Hist. de la Palestine*, pp. 95, 100).

The book of Haggai contains four short prophecies delivered between the first day of the sixth month and the twenty-fourth day of the ninth month—that is, between September and December—of the second year of Darius the king. The king in question must be Darius Hystaspis, who came to the throne 521 B.C. Scalliger, Druhus, and other older writers think of Darius (see 124 B.C.), but this is impossible, since in chap. i. 3 Haggai speaks of old men as still alive who had seen the first temple in its splendour before 587 B.C.² The language of the prophet suggests the probability that he was himself one of those whose memories reached across the seventy years of the captivity, and that his prophetic work began in extreme old age. This supposition agrees well with the shortness of the period covered by his book, and with the fact that Zechariah, who began to prophesy in the same autumn and was associated with Haggai's labours (Ezra v. 1), afterwards appears as the leading prophet in Jerusalem (Zech. vi. 1-4). We know nothing further of the personal history of Haggai from the Bible. Later traditions may be read in Carpenter's *Introduction*, para. 3, cap. xvi. On the mention of Haggai in the titles of several psalms in the Septuagint (Psalm cxcviii, cxi-cxviii) and other versions, see Koehler's *Wessungenen Haggai's*, p. 32. These titles are without value, and moreover vary in MSS. Elsewhere did not find them in the Hexaplar Septuagint.³

In his first prophecy (i. 1-11) Haggai addresses Zerubbabel and Joshua, rebuking the people for leaving the temple unbuilt while they are busy in providing panelled houses for themselves. The prevalent famine and distress are due to God's indignation at such remissness. Let them build the house, and God will take pleasure in it and

acknowledge the honour paid to Him. The rebuke took effect, and the people began to work at the temple, strengthened by the prophet's assurance that the Lord was with them (i. 12-15). In a second prophecy (ii. 1-9) delivered in the following month, Haggai forbids the people to be disheartened by the apparent meanness of the new temple. The silver and gold are the Lord's. He will soon shake all nations and bring them choicest gifts, to adorn His house. Its glory shall be greater than that of the former temple, and in this place He will give peace. A third prophecy (iii. 10-19) contains a promise, enforced by a figure drawn from the purely ritual, that God will remove famine and bless the land from the day of the foundation of the temple onwards. Finally, in iii. 20-23, Zerubbabel is assured of God's special love and protection in the impending catastrophe of kingdoms and nations to which the prophet had formerly pointed as preceding the glorification of God's house on Zion. In thus looking forward to a shaking of all nations Haggai agrees with earlier prophecies, especially Isa. xlii-xlii, while his picture of the glory and peace of the new Zion and its temple is drawn from the great anonymous prophet who penned Isa. lx and lvi. The characteristic features of the book are the importance assigned to the personality of Zerubbabel and the almost sacramental significance attached to the temple. The figures fixed on Zerubbabel, the chosen one of the Lord, due to Him as His anointed king (*cf.* Jer. xxi. 24), are a last echo in Old Testament prophecy of the theocratic importance of the house of David. In the book of Zechariah Zerubbabel has already fallen into the background and the high priest is the leading figure of the Judean community.⁴ The stem of David is superseded by the house of Zadok, the kinglyship has yielded to the priesthood, and the extinction of national hopes gives new importance to that strict organization of the hierarchy for which Ezekiel had prepared the way by his sentence of disfranchisement against the non-Zadokite priests.

If his attitude to Zerubbabel forms a link of connexion between Haggai and the prophets before the captivity, his post-exile standpoint is characteristically marked in the central importance which he attaches to the temple. The prophets who spoke under the shadow of the first temple held quite another language.⁵ To Isaiah and Jeremiah the religion of Israel and the holiness of Jerusalem have little to do with the edifice of the temple. The city is holy because it is the seat of Jehovah's sovereignty on earth, exerted in His dealings with and for the state of Judah and the kingdom of David. The proof that Jehovah's throne is in Jerusalem lies in the history of what He has done for His people, or, if a visible pledge is needed, it must be sought not in the temple but, in accordance with antique ideas, in the ark (*Jer.* iii. 16) or in the altar with its sacred flame (*Isa.* xlii. 1, xlii. 9). But, in the desolation of Jerusalem, the extinction of the political life with which all religion had till then been inseparably bound up gave a new meaning to the old prophetic doctrine that the service of Jehovah is the true vocation of Israel—a new significance to the ruined temple and all its ordinances of worship. "The holy and beautiful house where our fathers praised Thee" (*Isa.* lxi. 11) was a chief thought of the sorrowing exiles (*Lamentations, passim*), and to one anonymous writer the Lord's vengeance on Babylon appears eminently as vengeance for His temple (*Jer.* i. 28). The great prophet of the captivity—the author of *Isa.* xl—

¹ In Bleek's *Einleitung*, 4th ed., p. 434.

² Darius Nothus was thought of because Ezra iv. 6-23 seems to require an Artabanus before him. But it is now generally admitted that these verses refer to the building of the wall of Jerusalem, and in chronological order should follow chaps. v. vi. The Rabbinical commentators differ in their usual ignorance on points of history make Darius the son of Artabanus and father.

³ See the note on Ps. cxi. v. in Field's *He captiv.*

⁴ After the foundation of the temple Zerubbabel disappears from history and lives only in legend, which continued to busy itself with his story, as we see from the apocryphal book of *Esdras* (*cf.* *Desmoulin, Hist. de la Palestine*, chap. 1).

⁵ Compare for example *Jer.* vii.

⁶ Haggai (ii. 14) attaches no value to altar and sacrifices so long as the temple is unbuilt.

xvi—pictures the Israel of the restoration no longer as an earthly state but as a world-patriarch, a mediator of people gathered round the sanctuary and holding forth amidst the nations the true pattern of the knowledge and service of the living God till all the ends of the earth shall look to Him and be saved. Under the limitations of the old dispensation neither see: no people could separate the realization of this great conception from the restoration of the visible centre of Israel's worship in the temple at Jerusalem. The prophet had pointed to Cyrus by name as the rebuilder of Jerusalem and the founder of the temple (Isa xlv 1, 28, lv 11), and the captives whose hearts were touched by his burning words, and who availed themselves of the decree of that monarch (538 B.C.) to repeople the desolate places of Judah, looked for the speedy advent of the time when the glory of Jehovah displayed in His house on Zion should draw to Jerusalem the willing homage of all nations (Isa lvi, lv 7, lvi 1-6). The actual experiences of the returning exiles fell as far short of these bright hopes as the Israel of Zerubbabel and Joshua fell short of the ideal regenerate nation to which the prophet had promised the heritage of Jehovah's glory. Scarcely was a settlement effected when difficulties and misfortunes began to thicken about the little colony. The anger of the Lord seemed still to rest on Jerusalem and the cities of Judah (Zech 1, 12), whose inhabitants soon ceased to come down from the Persian court, and had to struggle with poverty and famine as well as with the hostility of their neighbours. Amidst such discouragements the first zeal soon grew cool, and the work of rebuilding the sanctuary lay practically untouched till Hagai arose sixteen years later.

What he actually been effected during these years for the restoration of the temple is a question of some difficulty. It seems safest to stick to the explicit contemporary evidence of Hag 1, 18 (cf. v 15 and Zech viii 6) which gives the sixth month of the second year of Darius—after Hagai had begun to preach—as the date when the temple was founded by Zerubbabel and Joshua. On the other hand, the book of Ezra, in its present shape as edited and partly composed by the much later author who wrote Chronicles, conveys the impression that huge gifts for the temple were offered by the leading Jews on their first return (Ezra ii 68, 69), that the foundation of the house was laid by Joshua and Zerubbabel in the second year of the return (Ezra iii 1), and that the work was thereafter interrupted by the opposition of the Jews' enemies till the reign of Darius. It appears probable, however, that the Chronicles has somewhat dislocated the order of events, especially by taking the official consecration in Ezr. iv to refer to the temple, whereas it really refers to the building of the city walls. This oversight might readily involve the antedating of the foundation ceremony described in Ezr. i 1-15, which seems to be identical with the account of Hagai, speaks of, since the actors are the same, and the chief feature in the description which does not belong to the usual liturgical ceremony of the Chronicles recalls Hag 1, 2, Zech vi 7-10. Again, the verses Ezra ii 68, 69 seem really to refer to a collection made in the time of Nehemiah, having been transcribed from a history of that period (part of which is preserved in the canonical book of Nehemiah) along with the ancient list which occupies the first part of Ezra i. But they are not part of the list, as appears from a comparison of Ezra ii 68-71 with Neh viii 64-viii 1. If this criticism is just, the Translators of Ezra ii as Nehemiah, not Zerubbabel, and the usual arguments for identifying the latter with Shebazzar—whom Cyrus, according to Herodotus, appointed to govern the province of Lydia, and the first high of the Jewish colony, in accordance with Isa lxi 28, 1, 10, was, to deny that the Persians could effect the restoration without effort of theirs. This hope was frustrated, Shebazzar presumably having taken up his task with the usual consciousness of an Oriental governor, that in, having done nothing, though the work was nominally in hand all along (Ezra v 16). The advancement of Zerubbabel to the governorship may have given Hagai his opportunity.

In the confused state of the chronology of the book of Ezra it may also be a question when the Persians sought to join the Jews and was repulsed. That the relation of Ezra vi 1-4 is historical seems

to be established against objections which have been taken to it by the identification of Zerubbabel, which A. V. Gutschmidt has suggested by an ingenious historical combination with the aid of the Assyrian monuments (*Neue Beiträge*, p. 146). Compare also Jer. xli 15 for the antiquity of the Samaritan claim to worship with the Jews. But from Ezra v, and especially from Zech ii, it may be questioned whether the opposition of the Samaritans arose before the time of Haggai and Zerubbabel. See on the whole question Schürer, *Die Dämonen der ersten Tempelbauzeit*, in the *Zeitschrift für die Kunde des Morgenlandes*, 1887.

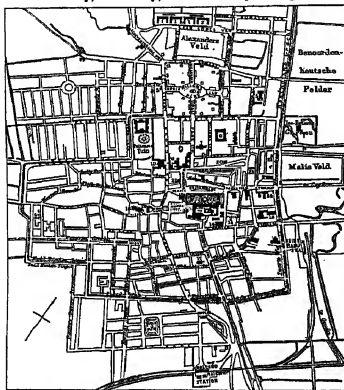

Such indifference to the undertaking, which held a chief place in the first ardour of the returning exiles, had a deeper significance than at once occurs to our modern habits of thought. The restoration of the temple and its worship was connected in every mind with the doctrine that the service of Jehovah was the true national vocation of Israel, and the apathy that Hagai rebukes showed the people to have forgotten in the struggle for material welfare their ideal calling as the nation of the true God. In its proofs touched the conscience of the Jews, and the book of Zechariah enables us in some measure to follow the course of a religious revival which, starting with the restoration of the temple, did not confine itself to matters of ceremony and ritual worship. On the other hand, Hagai's treatment of his theme, practical and effective as it was for the purpose in hand, moves on a far lower level than the aspirations of the great evangelical prophet who inspired the people at their first return. To the latter the material temple is no more than a detail in the picture of a work of restoration eminently ideal and spiritual, and he expressly warns his hearers against attaching intrinsic importance to it (Isa. lxxvi 1). To Hagai the temple appears so essential that he teaches that while it lay waste the people and all their works and offerings were unclean (Hag 1, 14). In this he betrays his affinity with Ezekiel, who taught that it was by the possession of the sanctuary that Israel is sanctified (Ezek. ixxvi 28). In truth the new movement of religious thought and feeling which started from the fall of the Hebrew state took two distinct lines, of which Ezekiel and the anonymous prophet of Isa. xl-lxxvi are the respective representatives. While the latter developed his great picture of Israel the mediatorial nation, the systematic and piously mind of Ezekiel had shaped a more material conception of the religious vocation of Israel in that picture of the new theocracy where the temple and its ritual occupy the largest place, with a sanctuary which is set in express contrast to the older conception of the holiness of the city of Jerusalem (cf. Ezek. xliii 7 seq. with Jer. xxxi 40, Isa. vi 5), and with a supreme significance for the religious life of the people which is expressed in the figure of the living waters issuing from under the threshold of the house (Ezek. xlvii). It was the conception of Ezekiel which permanently influenced the citizens of the new Jerusalem, and took final shape in the institutions of Ezra. To this consummation, with its necessary accompaniment in the extinction of prophecy, the book of Hagai already points.

Eschatological Hope.—The elaborate and valuable German commentary of Köhler (*Erlangen*, 1880) forms the first part of his work on the *Nachholische Propheten*. Rankin's *Commentary* (Minster, 1886) is the work of a Roman Catholic. Hagai has generally been treated as a work on all the prophets, as by Ewald (3d ed., 1868, Eng. trans., vol. vi, 1878), or alongside the other minor prophets, as by Hitzig (3d ed., Leipzig, 1868), Keil (1866, Eng. trans., Edinburgh, 1878), and Pusey (1876), or with the other post-exilic prophets as by Köhler, Frensdorff (Göttingen, 1876), Döder (1876), and others. The older literature will be found in books of introduction or in Rosenmüller's still useful *Soloth*. The latest commentary of Marcus may be specially mentioned. On the place of Hagai in the history of Old Testament prophecy, see Duhm, *Die Propheten des Alten Testaments* (Bonn, 1875).

HAGUE, THE (in Dutch, *de Gravinkke*; in *den Haag*, in French, *La Haye*, and in Modern Latin, *Haga Comitis*), a town of the Netherlands, in the province of South Holland, 13 miles N.W. of Rotterdam, 10 miles S.W. of Leyden, and 2 miles inland from the German Ocean. It is con-

¹ Ezra ii 2 seems to show that at the return Zerubbabel was merely one of the Jewish elders. The opposite impression is due solely to the punctuation.

nected with both Rotterdam and Leyden by the "Holland Railway," and with Utrecht by the railway of the Rhine. Besides being the chief town of the province, the Hague is the usual residence of the court, and the seat of the Government, the states-general, the high council of the Netherlands, the council of state, the chamber of accounts, and various other administrative bodies. The character of the town are quite in keeping with its political position. It is "the handsomest, the most fashionable, and the most modern-looking" town in the Netherlands. D'Amicis rightly describes it in his *Olanda* as half Dutch half French. Broad and regular streets, extensive avenues and drives, and spacious squares well planted with trees, are the main features of its general plan; large and beautiful buildings are numerous; and the population consists for the most part of Government officials and members of the nobility, the army, and the navy. A good idea

Plan of the Hague.

of the place is obtained by passing along the Vijverberg or Fishpond Hill, which takes its name from the large basin of water which it skirts, the Voorhout, and the Willemspark, next through Java Street and Sumatra Street, and then the Buitenhof or Outer Court, the Binnenhof or Inner Court, the Plein, the Keuterdijk, and the Grote Markt. Willemspark was laid out by King William II., and in 1869 it was chosen as the site of the national monument in memory of the recovery of independence in 1813, executed by Wasing, Pietersen, and Koelman. The Plein, a square bordered with the offices of the various ministers and the high council, is adorned with a statue of William I., the "father of his people," by Louis Royer; an equestrian statue of the same prince, by the count of Nieuwerkerke, is placed in front of the royal palace; and there is a statue of William II. by Georges in the Buitenhof.

The centre of the Hague, both historically and topographically, is the buildings of the court. The oldest portion was founded by Count William II., "king of the Romans," in 1249. A handsome Gothic building, with towers at each corner of the façade, contains the great or knights' hall, a noble chamber 130 feet in length, 62 feet in breadth, and 69 in height, in which the states of the Netherlands abjured their allegiance to Philip II. of Spain, and in front of which the grey-headed Olden-Barneveldt lost his life in 1619. To the south-east of the hall is the tronzaal, or throne room, in which the second chamber of the states-general holds its sittings; and to the west is the meeting-place of the first chamber. The archives of the kingdom and several Government offices are in the same range of buildings. The royal palace proper was purchased by the states of the Netherlands in 1595, rebuilt by Prince William III., and extended by King William I. The palace of the prince of Orange was founded about 1720 by Count Unico William of Wassenaar Twickels; the palace of Prince Frederick of the Netherlands dates from 1825 to 1828; the palace of Prince Henry was erected in 1743 for the deputies of Rotterdam; and the palace of Prince Alexander was in the 17th century the house of John de Witt, pensionary of the council. Among the public institutions of the Hague, the following are the most important:—the royal library, with upwards of 100,000 volumes, and a collection of manuscripts, coins, and gems, erected between 1734 and 1738; the Museum Meermanno-Westreenianum, comprising books, manuscripts, maps, plates, pictures, antiquities, and curiosities; the royal picture gallery in the Prinse-Mauritz-Huis, which was founded in 1633 by Prince John Maurice of Nassau-Siegen, governor of Brazil; the Vijverberg hôtel, with a collection of curiosities; the town museum of antiquities and modern art; the zoological gardens, founded in 1832; the royal school of design and music; and the new buildings for the arts and sciences, erected in 1874. Of the fourteen churches of the Hague five belong to the Dutch Reformed communion, six to the Roman Catholics, and one to the Old Catholics; two are Episcopal, one German Evangelical, and two Apostolical. There are also two synagogues and one Greek chapel. Architecturally the Grote Kerk, under the patronage of St James, is the most noteworthy; it is 300 feet long by 154 broad, and has a lofty tower and spire; in the interior are the sepulchral monuments of James Baron of Wassenaar Obdam, a Dutch naval hero, of Gerrit Assendelft, and of Philip, landgrave of Hessen-Philippthal. The Willemskerk was a present of William III. to the Reformed community of the Hague. The principal industries of the town are iron-casting, copper and lead smelting, cannon-founding, the manufacture of furniture and carriages, silk-dyeing, liquor-distilling, lithography, and printing. In 1822 the population of the Hague was only 17,480; in 1732 it was estimated at 34,000; in 1796, inclusive of the inhabitants of Scheveningen,—a watering-place now connected with the town by a tramway line,—it was 41,266; in 1811, 42,150; in 1830, 56,106; in 1840, 58,521; and in 1860, 66,329. In 1860 it was 78,405, and in 1870, 91,328. At the last date 52,600 belonged to the Dutch Reformed Church; 27,486 were Roman Catholics, 3471 Dutch Jews, and 148 Portuguese Jews. In 1874 the total was stated at 94,895. The Hague, mentioned as early as 1097 in a document by Count Floris II., seems originally to have been a shooting lodge of the counts of Holland. Under William II. it became a residence of the court; and in the 16th century it begins to be called a town, though for long after, down even to the time of Louis Napoleon, it was as frequently described as a village. In 1479 the soldiers of Maximilian of Austria put the place to ransom; in 1595 it was the scene of the martyrdom of Johannes Ploterius (Jan de Bakker of Woerd); in 1628 it was plundered by the people of Gubbeldingen; and in 1679, 1678, and 1674 it was laid waste by the Spaniards. In 1576, it was in 1584 the seat of the sessions of the States of Holland. Houses were constructed round the town in 1620. In 1672 it was the scene of the famous assassination of the brothers De Witt. It was at the Hague that the convention was arranged in 1710 between the German emperor, the king of Prussia, the emperor of Russia, and the maritime powers, for the maintenance of the neutrality of North Germany, it was at the Hague that the Triple Alliance of 1717 was concluded, and that the peace of the same year was signed between Spain, Savoy, and Austria. From 1788 to 1787 the town had its full share in the civil disturbances of the country. In 1808 it was made the seat of the Government administrative offices.

HAHN, AUGUST (1799–1868), German Protestant theologian, was born March 27, 1792, at Giessostelshausen near Eisenberg, and after attending the Eisenberg gymnasium, entered the university of Leipzig as a student of theology in 1810. After holding an educational appointment in Wittenberg for some time, he in 1819 was nominated professor extraordinarius of theology at Königsberg, and in the following year received a pastoral charge and a superintendency in that city. These posts, however, he soon resigned on his promotion in 1821 to be professor ordinarius. In 1826 he removed as professor of theology to Leipzig, where, hitherto unengaged only as editor of *Bardassens, Maier's*, and *Ephraim Syrus*, he came into extraordinary prominence as the author of a treatise, *De rationalismi quo dictum est a iudaeis et quoniam natu alismo contradietione rationis* (1827), and also of an *Offene Erklärung an die Evangelische Kirche in Preussen* (1837), in which he endeavoured to convince the rationalists that it was their duty voluntarily and at once to withdraw from the national church. In 1833 Hahn was called to Breslau as theological professor and consistorial councillor, and in 1844 he became "general superintendent" of the province of Silesia. He died at Breslau on May 13, 1868. Though uncompromising in his "supernaturalism," he did not altogether satisfy the men of his own school by his own doctrinal system. The first edition of his *Lehrbuch des christlichen Glaubens* (1828) was freely characterized as lacking in consistency and as detracting from the strength of the old positions in many important points. Many of these defects, however, he is considered to have remedied in his second edition (1857). Among the other literary labours by which Hahn is best known are his edition of the Hebrew Bible (1833) and his *Biblische Symbole und Glaubensregeln der apostolisch-katholischen Kirche* (1842, 2d ed. 1877). A volume of *Privatgen* was published in 1852.

HAHN, JOSEPH GEORGE VON (1810–1869), an Austrian traveller, to whom we are indebted for most of our knowledge about the Albanians, was born at Jena in 1810. After travelling for some time under the auspices of the Vienna academy, he entered the Austrian consular service, in which he rose to be consul general in Greece. He died at Jena 23d September 1869. In his great work *Albaneser Studien* (Jena, 1854), he treats at once of the geography, the history, the archaeology, the linguistic affinities, and the folk-lore in this remarkable country and people, and the book at once took rank as a scholarly and authoritative production. He had previously (1851) published *Bemerkungen über die Albanesischen Albaner* (Vienna, 1851). In 1853 he undertook a journey along with Mayor F. Zach from Belgrade to Salonika (Thessalonica), for the purpose mainly of ascertaining the feasibility of constructing a railway from the Danube to the Aegean, and an account of their experiences was published in the *Denkschriften der Kaiserl. Akademie der Wissenschaften zu*

Wien, *Phil. Hist. Klasse*, Bd. xi., Vienna, 1861. This paper, reprinted in 1871, contained valuable matter in regard to the Albanians, and especially in regard to their geographical distribution. Another journey undertaken in 1863 furnished material for a second contribution to the *Denkschriften* (*Phil. Hist. Klasse*, 1867)—"Reise durch die Gebiete des Drin und Wardar." Since the author's death a large work has appeared under the title of *Segensreichliche Studien* (Jena, 1872–73), in which he deals liberally with numerous questions in comparative mythology.

HAHNEMANN, SAMUEL CHRISTIAN FRIEDRICH (1755–1848), the founder of the homoeopathic system of medicine, was born at Meissen in Saxony, 10th April 1755. He studied first at the "lector's school" of Meissen, and thereafter as a student of medicine at Leipzig and Vienna. He took the degree of M.D. at Erlangen in 1779, and after acting as physician at various places he returned in 1789 to Leipzig, where he largely occupied himself in the translation of medical works. While working at Cullen's *Materia Medica*, he was struck by the contradictory account given of the properties of Peruvian bark. He had previously meditated much on the unsatisfactory nature of the science of medicine, and, after much reflection and many experiments, he became convinced of the truth of the principle *similia similibus curantur* (see HOMŌOPATHY), &c., &c. For a disease is the very thing that would in a healthy person produce the symptoms of such disease. Further experiments convinced him that the conventional doses produced symptoms of unnecessary and dangerous violence, and this led to another principle, that of minimum doses, according to which the benefit to be derived from a medicine can be fully obtained by the administration of a very small quantity. Firmly convinced of the truth of these principles, Hahnemann spent the rest of his life in making them known to the world. He encountered much opposition, and in 1821 was forced to leave Leipzig, as he was not allowed to dispense his own prescriptions. The grand duke of Anhalt-Köthen, however, appointed him his physician, and at Köthen he resided till 1835 when he removed to Paris. He died 2d July 1843. Hahnemann was a man of remarkable courage and perseverance. He not only sacrificed his immediate interests for the sake of his convictions, but made many painful experiments upon his own person.

Hahnemann's chief work, in which he expounds his system, is his *Organon der rationalen Heilkunde* (Dresden, 1810, 6th ed., Köthen, 1866, English translation by Dudgeon, London, 1848). His other important writings are *Principia medicinae homoeopathicae* (3 vols., Leipzig, 1805), *Ratio anatomico-medica* (8 vols., Dresden, 1811), *Die chronischen Krankheiten* (4 vols., Dresden, 1828–50). His smaller writings have been edited by Siegf. (3 vols., Dresden and Leipzig, 1829–34). See also Albrecht's *Hahnemann's Leben und Werke* (3d ed., Leipzig, 1875).

HAIDARABAD See HYDERABAD.

HAIDINGER, WILHELM VON (1795–1871), a mineralogist, geologist, and physicist of considerable note, was born at Vienna, February 5, 1795. His father, Karl Haidinger, contributed largely to the development of mineralogical science in the latter half of the last century. Having studied at the normal school of St. Anne, and attended classes at the university, Wilhelm, at the age of seventeen, joined Professor Mohs at Graz, and five years later accompanied the professor to Freiberg on the transfer of his labours to the mining academy of that Saxon El Dorado. In 1823 Haidinger visited France and England with Count Breunner, and, journeying northward, took up his abode in Edinburgh. He translated into English, with additions of his own Mohs's *Grundriss der Mineralogie*, published at Edinburgh in three volumes under the title *Treatise on Mineralogy*, 1826. After a tour in northern

Cervus Eldi, *Cervus hippelaphus*, and *Cervus vaginatus*. Among the birds, of which 172 species are described by Mr. Swinhoe in his paper in *The Ibis*, 1870, there are eagles, notably a new species *Spizopus Rutherfordi*, buzzards, hawks, larks, owls, cuckoos, and woodpeckers. The *Upupa cydonensis* is familiar to the natives as the "bird of the La matons," and the *Palawanus pyraeas* as the "sugar-cane bird."

Hainan, as already indicated, forms a fœo or department of the province of Kwang-tung, though strictly it is only a portion of the island that is under Chinese administration, the remainder being still occupied by unsubjugated aborigines.

The department contains three *chow* and ten *hsien* districts.—Kwang chow hsien, in which the capital is situated, Tung an hsien, the only inland district, Wen ching hsien, in the north-east of the island, Hui-tung hsien, Lo 'hui hsien, Lang-shui-hsien, Wan-chow, Ai-chou (the southmost of all), Kan en-hsien, Ching hui-hsien, Tan chow, Lan-kao-hsien, and Chang mu-hsien. The capital Kwang chow fœo is situated in the north about 10 li (or 3 miles) from the coast on the river. It is a well-built compact city, and its temples and examination halls are in good preservation. The population is frequently stated at 200,000, but, according to C. C. Stuhlmann in the *Globe* for 1876, it is only 100,000. Carved articles in coco-nuts and scented woods are its principal industrial product. In 1680 it was made the seat of a Roman Catholic mission by Benoit de Mathes, a Portuguese Jesuit, and the old cemetery still contains about 113 Christian graves. The port of Kwang-chow fœo at the mouth of the river, which is usually dry at low water, is called simply Hoi-hov, or in the court dialect Hui-Kow, i.e., seaport. The two towns are united by a good road, along which a large traffic is maintained partly by coolie porters but more frequently by means of wheelbarrows, which serve the purpose of cabs and carts. The net value of the trade of the port, that is, the foreign and native imports minus the re-exports and the native imports of local origin, rose from 684,772 liak taels in 1876 to 1,215,056 in 1878. Out of 182 vessels engaged in the foreign trade in 1878 with a tonnage of 87,290 tons, 152 were British, with a tonnage of 70,078 tons. The exports, comprised leather, hides, skins and tallow, sugar to the value of 204,427 taels, hemp, galangal, lung-gan pulp, grass cloth, and silk, and sesamum to the value of 41,936 taels.

The inhabitants of Hainan may be divided into three classes, the Chinese immigrants, the civilized aborigines or Shui-li, and the wild aborigines or Shang-li. The Chinese were for the most part originally from Keang-se and the neighbouring provinces, and they speak a peculiar dialect of which a detailed account by Mr. Swinhoe is given in *The Phoenix*, a *Monthly Magazine for China*, &c., 1870. The Shui-li as described by Mr. Taintor, are almost of the same status as the Chinese, but have a more decided copper colour, higher cheek-bones, and more angular features, while their eyes are not oblique. Their hair is long, straight, and black, and their beards, if they have any, are very scanty. They till the soil and bring rice, fuel, timber, grass cloth, &c., to the Chinese markets. The Sheng-li or La popai, called also La, Le, or Lany, are probably connected with the Laos of Siam, and the Lolos of China. Though not gratuitously aggressive, they are highly intractable, and have given great trouble to the Chinese authorities. Among themselves they carry on deadly feuds, and revenge is a duty and an inheritance. Though they are mainly dependent on the chase for food, their weapons are still the spear and the bow, the latter being made of wood and strung with bamboo. In marriage no avoidance of similarity of name is required. The bride's face is tattooed according to a pattern furnished by the bridegroom. Their funeral mourning consists of abstaining from drink and eating raw beef, and they use a

wooden log for a coffin. When sick they sacrifice oxen. In the spring time there is a festival in which the men and women from neighbouring settlements move about in gay clothing hand in hand and singing songs. The whole population of the island is estimated at about 2½ millions. At its first conquest 23,000 families were introduced from the mainland. In 1300 the Chinese authorities assign 166,257 inhabitants, in 1370, 291,000, and in 1617, 250,524, and in 1835, 1,350,000.

It was in 111 A.D. that Lu To To, general of the emperor Wu-ti, first made the island of Hainan subject to the Chinese, who dwelt until the two prefectures, Tan shih or Diangping in the south, so-called from the long river of the native "king," and Chu yu or Pearl River in the north. During the decadence of the elder branch of the Hui dynasty the Chinese supremacy was weakened, but in 49 A.D. the natives were led by the son-in-law of Ma yu in Tong lang to make a new tender of their allegiance. About this time the whole island took the name of Chai yu. In 627 A.D. the name of Kwang chow came into use. On its conquest by the generals of Kublai Khan in 1274 the island was incorporated with the western part of the province of Kwangtung in a new sheng Hui-shih Hui-shih, i.e., the circuit north of the sea and south of the sea. It was thus that Hui-shih, or district south of the sea or shih-shih, came into use as the name of the island, which, however, has borne the official title of Kwang chow fœo, probably derived from the Kwang-shui or Jade Mountains, even since 1870, the date of its elevation into a department of Kwangtung. For a long time Hainan was the refuge of the turbulent and lawless character of the disposition for delinquent officials. It was there, for example, that Su Shih or Su Tung po was banished in 1097. From the 15th to the 19th century pirates made the intercourse with the mainland dangerous, and in the 17th they were considered to furnish the mercenaries were allowed to convey their goods across only by the narrow channel from Su-shih. Since 1860 the presence of English men of war has put an end to this evil. According to the treaty of Peking, the capital Kwang-chow and the harbour Hui-Kow were opened to European commerce, but it was not till 1876 that advantage was taken of the permission.

See *Journal of the Royal Geographical Society*, 1868, May, 2, and *Stat. Sketch of the Island of Hainan*, in *Journal of the China Branch of the Royal Geog. Soc.*, vol. vi (1874), pt. 1, p. 111, and *Chinische Provinzen*, Kwangtung, in *Reise nach Ostasien*, 1874, China, China, Hongkong, Japan, &c. See also the *Journal of the Royal Geog. Soc.*, 1874, pt. 1, p. 111, and *Journal of the Royal Geog. Soc.*, 1874, pt. 1, p. 111, and *Journal of the Royal Geog. Soc.*, 1874, pt. 1, p. 111.

HAINAU (officially HANAU), a town in the Prussian province of Hesse, circle of Goldbezg-Hanau and government district of Lagnitz, is situated on the Rapid Deubach and on the railway from Breslau to Dresden, 12 miles N.W. of Lagnitz. It has an Evangelical and a Roman Catholic church, and manufactures of woollen and cotton cloth, gloves, leather, locks, and iron ware. Near Hanau the Prussian cavalry inflicted a defeat on the French rearguard, 20th May 1813. The population of the town in 1875 was 6351.

HAINAUT, one of the nine provinces of the kingdom of Belgium, bounded E and N by Namur, Brabant, and Flanders, which are also Belgian provinces, and to the S. and W. by the French département du Nord. The name is doubtless derived from the little river Haine, which runs nearly due east and west past the town of Mons, and falls into the Scheldt not far from Condé. Hainaut is well-wooded and hilly in the east and south east, where it is partly covered by the Ardennes, the rest of the province is a pleasantly diversified, fertile, and well-cultivated plain land, which produces all kinds of cereal crops, flax, tobacco, chicory, and beetroot. The long and narrow coal-field which, with some smaller stretches from Axtel-Chapelle to the sea near Boulogne, passes through the middle of Hainaut, underlying a district of about 190,000 acres, its centre is about Mons, whence it extends westward to Valenciennes, eastward to Charleroi. At this latter town, named after Charles II. of Spain, who built it in 1666, are iron and copper works, marble and building stone are also largely quarried in Hainaut, the manufactures of this province are vigorous and good, ironware and cutlery,

¹ In German, *Hannau*; Flemish, *Hannegouwen*; French, *Hannaut*; the *Comitatus Hannegouwen* or *Hannoum* of Latin chronicles.

woollen and linen goods, glass, porcelain, and a variety of other articles are made, and are exported largely into France. Hannault, with a population of 959,354 inhabitants in 1876 (the largest in this respect of all the provinces), has an area of near 1400 square miles, and is therefore somewhat thickly peopled, for administrative purposes it is divided into six arrondissements, of which that of Mous is the chief, the others are Tournai, Charleroi, Ath, Soignies, and Thum, these again are subdivided into thirty-two cantons.

Formerly the county was nearly twice as large as the present province. In Charls's day it was inhabited by the Nevi, and did not get its present name till the 7th century, before which time it had become a county under its own lords. This dignity, at first more or less elective, but under hiseditary in the 9th century. Throughout the early Middle Ages Hannault was a purely agricultural district, owned by a numerous and very quarrelsome and disagreeable nobility. It possessed also no less than fifteen abbeys. It was famous in legend and history as the chosen land of claudy, and, however, himself a native of Valenciennes, faithfully reflects the character of his fatherland. In the 11th century Baldwin V. of Flanders occupied it, and Baldwin VI., by marrying the heiress to the county, permanently added it to the territories of his house. It was his descendant Baldwin IX., count of Flanders and Hannault, who justly earned himself first Latin emperor of Constantinople, in 1204.

In 1300 John of Avesnes, count of Hannault, became also count of Holland by right of his mother Adelaide, sister of William II. of Holland, it was his grandchild, Philippe, who in 1383 married the Prince of Wales, afterwards Edward III. Hannault went with Flanders, till it was occupied by Philip "the Good" of Burgundy in the war which lasted from 1324 to 1427. It finally fell to the house of Burgundy on the death of the unfortunate Jacob in 1479. With the other territories of Charles the Bold it passed with Mary of Burgundy in 1477 to the house of Austria, and remained thence till the peace of the Pyrenees in 1659, when part of the southern portion of the county was ceded to Louis XIV. as a reward for his services, and enlarged at Nimwegen in 1678. Thenceforth there are two Hannaults, the French and the Austrian, the latter answering to the present Belgian province. French Hannault (now a part of the department du Nord) had as its ancient capital Valenciennes, its chief towns are Combe, Cambrai, Mauberge, Lo Querno, Landreco, Avesnes, Givet, Chateaufort, Philippeville, which, on its name, to Philip II. of Spain, having been transferred out of a village called Congny into a town by Charles V. in 1555, was restored to the Netherlands in 1815. Austrian Hannault was overrun by the French in 1793, and annexed to France as the department of Jeumont in 1794, in 1814 it was made part of the kingdom of the Netherlands, and in 1830, as a matter of course, in the division of that kingdom, it became one of the provinces of the Belgian half.

The chief authorities are the Baron de Rottenberg's *Mémoires pour servir à l'histoire des Provinces du Namur, de Hannault, et de Luxembourg*, 1811-1848, and Jacques de Gues's *Antiquité du pays de Hannault*.

HAINBURG, or **HAIBURG**, a town of Austria, in the circle of Bruck, situated on the Danube 27 miles ESE of Vienna, is the seat of a district court of justice and of a tax-office. It occupies a part of the site of the old Celtic town Carnuntum, destroyed 251 A.D. Since the fire of 1837 Hainburg has become much improved, and is now a handsomely built town. It is still surrounded by ancient walls, and has a gate guarded by two old towers. There are numerous Roman remains, among which may be mentioned the altar and tower at the town-house, on the latter of which is a statue, said to be of Attila. A Roman aqueduct is still used to bring water to the town. Hainburg has a military school for engineers. The two important manufactures are tobacco, employing about 1700 hands, and needles, of which about 80 millions are annually turned out. On the neighbouring Hainburg is an old castle, built of Roman remains, which appears in German tradition under the name of Hainburg, was wrested from the Hungarians in 1042 by the emperor Henry III. At the foot of the same hill is a castle of the 12th century, where Ottocar, of Bohemia, was married to Margaret of Austria in 1252, earlier it was the residence of the dukes of Babenberg. Outside the town, on an island in the Danube, is the ruined castle of Rothenstein or Rothenstein, held by the Knights

Templar. Hainburg was besieged by the Hungarians in 1477, was captured by Matthias Corvinus in 1482, and was sacked, and its inhabitants massacred, by the Turks in 1683. Population (1869), 4178.

HAINICHEN, a town of Saxony, in the circle of Leipzig and the prefecture of Doblen, is situated on the Little Striegar, 15 miles NE of Chemnitz by railway. It is the seat of a royal court of justice, and has cigar and leather manufactures and a school of weaving. Its most important industry is the manufacture of flannels, baize, and similar fabrics, indeed it may be called the centre of this industry in Germany. The special whiteness and excellence of the flannel made in Hainichen is due to the peculiar nature of the water used in the manufacture. There are 32 spinning-mills in the town and environs, with about 2500 looms, of which between 300 and 400 are mechanical. There are also large dye works and bleaching establishments. Large quantities of both wool and cotton are spun and woven, and yarn spun elsewhere is brought to Hainichen to be woven about 3,850,000 lb of raw wool, worth about £600,000, is annually worked into material, some of which is exported to South America and eastern Asia. Coal is found in the neighbourhood, but does not repay the expense of working. Hainichen is the birthplace of Gellert, to whose memory a bronze statue was erected in the market place in 1855. The Clerical institution for the poor was erected in 1815. Population (1875), 8468.

HAIR is a substance which, from its various properties, and differences in stoutness, length, and strength, enters into a considerable variety of manufactures. Bristles are the stout elastic hairs obtained from the backs of certain breeds of pigs. The finest qualities, and the greatest quantities as well, are obtained from Russia, where a variety of pig is reared principally on account of its bristles. The best and most costly bristles are used by shoemakers, secondary qualities being employed for toilet and clothes-brushes, while inferior qualities are worked up into the commoner kinds of brushes used by painters and for many mechanical purposes. For artists' use and for decorative painting, brushes or pencils of hair from the sable, camel, badger, polecat, &c. are prepared. The hair of various animals which is too short for spinning into yarn is utilized for the manufacture of felt. For this use the hair of rabbits, hares, beavers, and of several other rodents is largely employed, especially in France, in making the finer qualities of felt hats. Cow hair, obtained from tanneries, is used in the preparation of roofing felts, and felt for covering boilers or steam-pipes, and for other similar purposes. It is also largely used by plasterers for binding the mortar of the walls and roofs of houses, and of late years it has to some extent been woven up into coarse friezes, horse cloths, railway rugs, and inferior blankets. The tail hair of oxen is also of value for stuffing cushions and other upholstery work, for which purpose, as well as for making the official wigs of law officers, baristers, &c., the tail and body hair of the yak or Thibet ox is also sometimes imported into Europe. The tail and mane hair of horses is in great demand for various purposes. The long tail hair is especially valuable for weaving into hair-cloth, mane hair and the short tail hair being, on the other hand, principally prepared and curled for stuffing the chairs, sofas, and couches which are covered with the cloth manufactured from the long hair. The horse hair used in Great Britain is principally obtained from South America, Germany, and Russia, and is sorting, cleaning, and working up into the various manufactures dependent on the material are industries of some importance. In addition to the purposes already alluded to, horse hair is woven into crinoline for ladies' bonnets, plaited into fishing lines, woven into bags for oil and cider presses, and into straining cloths for

brewers, &c., and for numerous other minor uses. The manifestations which arise in connexion with human hair are more peculiar than important, although occasionally fashions arise which cause a large demand for human hair. The fluctuations of such fashions determine the value of hair, but at all times long tresses are of considerable value. Grey, light, pale, and auburn hair are distinguished as extra colours, and command much higher prices than the common shades. The value of hair also increases very rapidly with increase in length. Thus while 8 inch hair sells at about 1s per oz., 36-inch hair will command a price as high as 80s per oz. Length beyond 36 inches is exceptional and commands fancy prices, the standard length in the hair trade being 18 inches. The light coloured hair is chiefly obtained in Germany and Austria, and the south of France is the principal source of the darker shades. In the south of France the cultivation and sale of heads of hair by peasant girls is a common practice, and hawkers attend fairs for the special purpose of engaging in this traffic. Hair 5 and even 6 feet long is sometimes obtained. Scarcely any of the "law material" is obtained in the United Kingdom except in the form of ladies' "combings." Bleaching of hair by means of peroxide of hydrogen is now extensively practised, with the view of obtaining a supply of golden locks, or of preparing white hair for mixing to match grey shades, but in neither case is the result very successful. Human hair is worked up into a great variety of wigs, scalp, artificial fronts, fuzzets, and curls, all for supplementing the scanty or failing resources of nature. The plating of human hair into articles of jewellery, watch guards, &c., forms a distinct branch of trade. For statistics, properties &c., of the human hair see *ANATOMY*, vol. 1 p. 898.

HAIRBELL See HAREBELL

HAIR TAIL (*Physalus leytus*), a marine fish, with a long band-like body terminating in a thread-like tail, and with strong prominent teeth in both jaws. Several species are known, of which one, common in the tropical Atlantic, not rarely reaches the British Islands.

HAIITI See HAITI

HAJDÚK, sometimes corrupted into *HEVDUKA*, is the plural form of the Magyar word *hajdú*, and was formerly used as the collective name of the undementioned towns (along with Vámos Pécs, population 8000) of the old privileged Hajduk district of Hungary, now included in the county of Hajduk.

Hajdú-Böszörmény, the second town in importance of Hajduk county, has about 11 miles to the N.W. of Debrecen, 47° 41' N lat., 21° 31' E long. It is the seat of a royal court of law, and was formerly the capital of the Hajduk district. Among the principal buildings are the old district court house, a Greek Catholic and two Calvinist churches, a Protestant gymnasium, the post and telegraph offices, and the savings bank. The fairs periodically held in the town attract people from a considerable distance. Population (1870) 19,308.

Hajdú-Dorog is a market-town situated about 10 miles to the N. of Böszörmény, with a Greek Catholic and a Calvinist church. At Dorog the Magyar adherents of the Greek Catholic Church are met with in great numbers. Population 8216.

Hajdú-Padhasz is a corporate town lying about 10 miles N. of Debrecen. It has a Calvinist church, post and telegraph offices, and a station on the railway from Nyiregyháza to Debrecen. Population 7024.

Hajdú-Nándas is a market-town, about 24 miles N.W. of Debrecen, with a large Calvinist church, a new school for girls, and a Protestant gymnasium. The surrounding country, although on the whole productive, assumes in the west a generally swampy character. Population 13,198.

HAJDÚ SZOBOSZLO is a corporate town, 12 miles to the S.W. of Debrecen, with which it is connected by railway. Among the principal buildings are a Calvinist church and school, and a royal law-court. Population 13,369.

The Hajduk district was made over to the Hajduks in 1605, with special privileges and the rights of nobility, by the Transylvanian prince Stephen Bocskay, as a reward for military services rendered him in his revolutionary campaigns. The inhabitants were exempted in their possessions by the act of 1618. From 1646 to 1660 the district was united to the county of North Bihar, but it afterwards received a separate cantonal organization. It now forms the principal portion of the new county of Hajduk, constituted in 1876, and including, along with the old Hajduk district, portions of the neighbouring counties of Szabolcs and Bihar. Debrecen is the capital, and the population is computed at about 163,000, mostly Magyar.

HAJIPUR, a municipal town in Muzaffarpur district, Bengal, situated on the east bank of the Gaudak, a short distance above its confluence with the Ganges opposite Patna, 25° 40' 50" N lat., 85° 14' 24" E long. It is said to have been founded about 500 years ago by one Hajj Ilyas, the supposed ramparts of whose fort, enclosing an area of 360 *bighas*, are still visible. Hajipur figures conspicuously in the history of the struggles between Akbar and his rebellious Afghan governors of Bengal, being twice besieged and captured by the imperial troops, in 1572 and again in 1574. Its command of water traffic in three directions makes the town a place of considerable commercial importance. Within the limits of the old fort is a small stone mosque, very plain, but of peculiar architecture, and attributed to Hajj Ilyas. Two other mosques and a small Hindu and Buddhist temple are in the town or its immediate vicinity. Besides the ordinary courts, the town contains a school, post-office, charitable dispensary, and distillery. The population in 1872 numbered 22,306, of whom 18,766 were Hindus and 3510 Mahomedans.

HAJJJI KHALFA Mustafa 'Im Abdallah, Kátib Chalepi (c. 1600-1658), commonly known as Hajji (or Haidji) Khalifa (more properly Hajji Khalifah), was the author of an encyclopedia in Arabic of Oriental biography and bibliography. He was born at Constantinople about the beginning of the 17th century of the Christian era, and after passing the earlier part of his life in military service, studied under Cadihádoh Effendi, a learned doctor at the Ottoman capital, and made great progress in Arabic literature and linguistic studies. In June 1633 he again accompanied the army to Syria, but while the troops were in winter quarters at Aleppo, he himself performed the pilgrimage to Mecca, whence he took the cognomen of Hajji, "Pilgrim." Returning in 1635 to Constantinople, he resumed his literary studies, and was supplied with visiting all the libraries and book shops, and compiling an inventory of their contents, together with notices of the authors of the various works. In 1638 he attended the lectures of Sheikh A'iy Mustafa'azadeh, whom he proposed to himself as an example to imitate in his future literary career. Besides his purely literary studies he also devoted himself assiduously to the sciences, and became well versed in logic, geometry, geography, astronomy, and the like. Nor were medicine and the occult sciences neglected by him, so that there were few of the subjects treated of in the works which he delighted to describe with which he was not more or less technically acquainted. About 1648 he was appointed assessor (*khalifa*) to the principal of the imperial college, whence he took the title of Khalifa, by which, with the prefix of Hajji (*Pilgrim*), he is commonly designated. He died in September 1658.

Besides his great *Bibliographical Lexicon*, he composed several other works, chiefly geographical and historical, of these the best known are *Ma'ane-i-Khalifa*, or *Etymological Tables*, *Tarikh-i-Kulur fi asyaa-i-Bihar*, a work on the science of naval warfare, *Adab-i-Namud* or "Mirror of the World," and one or two treatises on miscellaneous literary subjects. The language in which he wrote is Arabic, and the style is that which the virtuosi of his station would

lead us to expect,—correct and grammatical, fully classical, and abounding in technical terms and phraseology. Of the amount of his learning and of his industry in application to study his *Lexicon* is a lasting memorial. This is scarcely a work in the whole range of Arabic, Persian, and Turkish literature, no matter on what subject or science, but it will be found described in the best encyclopaedia, with every piece of collateral information which it was possible to procure or useful to mention. When a commentator that it is the Orientalist's habit to give figure titles to books, that often in no way indicate the nature of their contents, and that one is often obliged to wade through pages of irrelevant matter before coming across the author's name or the subject of the work, the labour expended on the production of Haki's book's book will be deemed amply justified. The work has always enjoyed a well-deserved reputation in the East, in this it attracted the attention of many European scholars, but we need only mention here the magnificent edition in seven thick, 6vo volumes by the eminent Arabic scholar Gustavus Fluegel published at Leipzig in 1855-1858 for the Grondel and Son Trust Fund of the Great Britain and Ireland. This edition is accompanied by a Latin page for page translation, indices, and notes, and is an indispensable adjunct to every library in which a collection of Oriental books is found. The Arabic title of the *Lexicon* is *Kashf al-mawarid 'an Asma' al-Kitab wa'l-Fann*. "The removal of doubts concerning the names of books and containing sources," and the Latin title adopted by Fluegel is *Lexicon Indisignificans seu de Significativitate Hagi Arabicorum*. After a short preface and an introduction of five chapters, comes the encyclopaedia proper, the articles in which are arranged in the alphabetical order of the names of the works described. The title of each book is given, a concise account of its contents, the name of the author, and the date when this could be ascertained, and in many cases the mutual phrase is also added to facilitate its identification. Besides the general bibliography, Fluegel's edition contains several appendices of great value to Oriental scholars and libraries. Copious notes and indices complete this splendid edition, one of the finest monuments of Oriental learning which Europe has produced.

HAKA (*Halacurus vulgaris*), a fish belonging to the family of cod-fishes (*Gadidae*), differing from the common cod in having only two dorsal and one anal fin. It is very common on the coasts of Europe and eastern North America, but its flesh is much less esteemed than that of the true *Gadus*. Specimens of fresh length are not scarce. A closely allied fish inhabits the coasts of Chih and New Zealand.

HAKIM, or, as the full title runs, **EL HAKIM BE-AMR-ELAH AMO 'ALAE MANSOUR** (985-1020), the sixth of the Fatimite caliphs, and the third of that dynasty ruling in Egypt, founder of the seat of the Druzes, was born in 985 A.D., was designated her apparent in 993, succeeded in 996, and died in 1020. For the principal events of his life and the leading features of his character the reader is referred to the article *Koyur* (vol vii p 751). See also *DAWSES* (vol vii p 484).

HAKLUYT, RICHARD (c. 1553-1616), geographer, was born of good family in or near London about 1553. He was elected "one of her Majesties scholars at Westminster," and it was while there that the bent of his future studies was determined by a visit to his cousin and namesake, Richard Hakluyt of the Middle Temple. His cousin's discourses, illustrated by "certain bookes of cosmographie, an universall mappe, and the Bible," had such an effect upon Hakluyt's mind that he resolved, if opportunity offered, to "peruse the knowledge and kind of literature." Entering Christ Church, Oxford, in 1570, "his excellence of study first performed," he fell to his intended course of readings and by degrees perused all the printed or written voyages and discoveries that he could find. He took his degree of B.A. in 1573-74, and we learn from the 'Towneyale MSS that two years later he was selected twice in the same year to receive gifts of money. It is highly probable that,

² The Hakluyts were a family of Welsh extraction, not Dutch as has been supposed. They appear to have settled in Herefordshire as early as the 13th century. The family seat was Eton, 2 miles S. of Leominster. Hugo Hakluyt was rewarded with £20 for that borough in the 36th year of Elizabeth I., 1564-5. See *Annals of Members of Parliament*, pt. i p 18.

³ "To one Mr Hakluyt, B.A. of Christ College in Oxford, the 13 of May (1576), by Dr Humphrey (professor of divinity), 10s. To one Mr Hakluyt, the 20 of June, 2s 6d." (First MSS Comm. 4th Report, Appendix, p 615.)

shortly after taking his degree of M.A. (1577), he commenced at Oxford the first public lectures in geography that "showed both the old imperfectly composed, and the new lately reformed maps, globes, spheres, and other instruments of this art."³

Hakluyt's first published work was his *Divers Voyages touching the Discoverie of America* (London, 1582, 4to). By reason of his great knowledge of these matters and his acquaintance with "the chiefest captaines at sea, the greatest merchants, and the best mariners of our nation," he was selected in 1583, at the age of thirty, to accompany Sir Edward Stafford, the English ambassador, to Paris in the capacity of chaplain. In accordance with the instructions of Secretary Walsingham, he occupied himself chiefly in collecting information of the Spanish and French movements, and "making diligent inquirie of such things as might yield any light unto our western discoverie in America." The first fruits of Hakluyt's labours in Paris are embodied in the most important production of his that has seen the light in modern times, it is entitled *A particular discourse concerning Western discoveries written in the year 1581*, by Richard Hakluyt of *Orforde*, at the request and direction of the right worshipfull Mr William Hakluyt being the comynge home of his two barckes.⁴ This long-lost MS, after failing to find a resting place in America, was finally acquired by Sir Thomas Phillips, and is now the property of Mr J. A. Fenwick of Thurstone House, Cheltenham. The object of the *Discourse* was to recommend the enterprise of planting the English race in the unsettled parts of North America. Hakluyt's other works consist mainly of translations and compilations, relieved by his dedications and prefaces, which last, with a few letters, are the only material we possess out of which a biography of him can be framed.

Hakluyt returned to England in 1584, and during his short stay he had the honour of leaving before Queen Elizabeth a copy of the *Discourse* "along with one Latin upon Aristotle's *Poetics*," which won for him, two days before his departure again for Paris, the grant of the next vacant prebend at Bristol. In the spring of the following year, feeling anxious about the reversion of the prebend, he again visited England, and exhibited in person, on the 24th May 1585, before the chapter of Bristol cathedral, the queen's mandate for the coveted vacancy already signed and sealed. Before the close of the year the reversion of it fell to him, and in 1586 he was admitted to the prebend, which he held, with his other preferments, till the time of his death.

While in Paris Hakluyt caused to be published the MS journal of Leondonniers or *Histon notable de la Florida*, edited by M. Baesmeier (Paris, 1586, 8vo). This was translated by Hakluyt and published in London under the title of *A notable historie containing four voyages made by certayne French Captaynes into Florida* (London, 1587, 4to). The same year *De Orbe Novo Petri Martyni Angles Descriptio orio illustrata, labore et industria Richarda Hakluyti*, saw the light at Paris. This work contains the exceedingly rare copperplate map dedicated to Hakluyt and signed P. G. (supposed to be Francis Guille), it is the first on which the name of "Virginia" appears.

In 1588 Hakluyt finally returned to England with Lady Stafford, after a residence in France of nearly five years. In 1589 he published *The Principall Navigations, Voyages, and Discoveries of the English Nation* (fol, London, 1 vol.) In the preface to this we have the announcement of the intended publication of the first terrestrial globe made in

⁴ That he was not in London is certain, as we know that the first lecture of the kind was delivered in the metropolitan on the 4th of November 1588 by Thomas Hood.

⁵ Now first printed from a contemporary MS, with an introduction by John Wood, LL.D., edited by Charles Deane, *Collections of Manuscript Soc.*, Camb. (3d), 1877, 8vo.

England by Molyneux (see Gloss). On the 20th April 1580 he was instituted to the rectory of Withingsett cum-Brockford, Suffolk. The magnum opus of Hakluyt is *The Principal Navigations, Voyages, Traffiques, and Discoveries of the English Nation* (fol., London, 1598-1600, 3 vols). Some few copies contain an exceedingly rare map,¹ the first on the Mercator projection made in England according to the true principles laid down by Edward Wright. Hakluyt's great work, though but little read, has been truly called the "pious epic of the modern English nation." It is an invaluable treasure of material for the history of geographical discovery and colonization, which has secured for its author a lasting reputation for research and industry.² In 1601 Hakluyt edited a translation from the Portuguese of Antonio Galvano, *The Discoveries of the World* (4to, London). On the 4th May 1603 he was installed prebendary of Westminster, and in the following year elected archdeacon of Westminster. In the licence of his second marriage (30th March 1604) he is also described as one of the chaplains of the Savoy, and will contains a reference to chambers occupied by him there up to the time of his death,³ in another official document he is styled D.D.⁴ His last publication was a translation of Fernando de Soto's discoveries in Florida, entitled *Virginia, richly valued* (London, 1609, 4to). This work was intended to encourage the young colony of Virginia, of which Hakluyt was so zealous a promoter, to whom England is more indebted for its American possession than to any man of that age.⁵

A number of Hakluyt's MSS., sufficient to form a fourth volume of his collections of 1599-1600, fell into the hands of Samuel Purchas, who inserted them in an abridged form in his *Pilgrimes* (1625-26, fol.). Others are preserved at Oxford (Bib. Bod. MS., Seld. B. 8), which consist chiefly of notes gathered from contemporary authors. Hakluyt died in 1616, and was buried in Westminster Abbey (November 20), by an error in the abbey register it stands under the year 1626. His best monument is the society that flourishes under his name. Founded in 1846 for the purpose of printing rare and unpublished voyages and travels, "it aims at opening by this means an easier access to sources of a branch of knowledge which yields to none in importance, and is superior to most in agreeable variety." The fifty-seven volumes that have been published by the society since its formation have been edited with great discrimination and care, and have come to be regarded as the standard text-books upon their respective subjects. Some are out of print, and others have passed through two editions. The latest volume published is a reissue in a new form of *The Itineraries Voyages*, the first work published by the society.

HIKODADJ, or HAKODATE, a seaport town of Japan, in the old province of Hokkaido, on the southern coast of the island of Yezo or Yeso, in 41° 49' N lat. and 140° 47' E long. Its general position, as has been frequently remarked, is not unlike that of Gibraltar, as the town is built along the north-western base of a rocky promontory (1100 feet in height) which forms the eastern boundary of a spacious bay, and is united to the mainland by a narrow sandy isthmus. At the time of Captain Perry's visit in 1851 few of the buildings of Hakodadi, with the exception of its temples and fire-proof warehouses, were more than one story high, and the roofs were made of slight shingles protected against the effects of wind-storms by heavy stones.

¹ Supposed to be the "new map" of the *Twelfth Night*, see in some 2. See *Trans. of New Zealand Soc.*, 1877-79, p. 1, 8vo.
² In 1809-12 was published a new edition of it by Woodfall & Evans in 5 vols. The last two contain pieces not comprised in the col. edition of 1698-1699.
³ *Westminster Abbey Registers*, edited by J. L. Chester, 1876, pp. 118.

⁴ Robertson, *Hist. of America*, vol. iv p. 171, 10th ed.

Since that date the town has increased considerably in extent, and many of the more modern buildings, such as the new custom-house and the residences of the Government officials, have been erected in a more solid European style. In 1870 there were four European hotels. A new bund or embankment has been constructed along the shore, and several quays of the town have been laid out in better fashion by the local authorities. Hakodadi is the residence of the governor of Yezo, and the seat of an arsenal. There are four Buddhist and three Shinto temples,—the most important of the former being the Zhioghen-jiu, or Country's Protector, built about 1830. A medical college is maintained in connexion with the Government hospital, and in the neighbourhood of the town an agricultural college has been opened since 1873. The Bay of Hakodadi, says Sir Rutherford Alcock, is completely land-locked, easy of access, and spacious enough for the largest vessels to ride in it, with deep water almost up to the shore, and good holding-ground. The Russians have for a considerable time used it as a winter station for their ships, because their own harbours on the coast of Kamchatka are annually frozen up. Their establishment formerly comprised a handsome consular residence, a hospital, warehouses, and workshops, but the consulate was removed from the port in 1871. Hakodadi has a large local trade, but neither its exports nor its imports are very extensive, and as a commercial centre it will not improbably be superseded by Endomae. The exports comprise awabi, cuttlefish, sea-weed, kisho demai (uriko), sea-otter skins, and deer skins, as many as 30,000 pairs of the last being sometimes shipped in a year. Lead and coal mines exist in the neighbourhood. There is telegraphic communication with Tokio (Yedo), and a new road has been made to Sapporo (Satapou). The population of the town is estimated at 30,000, in 1872 the foreign settlement had 23 residents. Hakodadi, originally a fishing village belonging to a local daimio, was purchased by the Government and incorporated in the imperial fief of Matema. It was opened to American commerce in 1854, and there are now also Danish, German, and English consuls. In 1808 the town was taken by the rebel fleet, but it was recovered by the emishi in 1809.

HAL, a town of Belgium, province of South Brabant, is situated on the Senne and the Chalewa canal, 9 miles SSW of Brussels. It has a beautiful Gothic church of the 14th century, very much resorted to by pilgrims on account of a famous miracle-working image of the Virgin. The church has been enriched by a large number of votive gifts, and contains a beautifully carved high altar of white marble. The principal industries are tanning, soap boiling, the manufacture of paper, and silk-refining. The population in 1869 was 6406.

HALA, or HALLA (formerly known as Murizibadi), a town in Hyderabad district, Sind, India, situated on the Ahgany canal and immediately connected with the Trunk Road at two points, 25° 48' 30" N lat., 68° 27' 30" E long. It was long famous for its glazed pottery and tiles, made from a fine clay obtained from the Indus, mixed with flints. The *sals*, or trouser-cloths, for which the town is also celebrated, are manufactured to the value of £750 yearly. Hala was built about 1800 in consequence of old Hala, 2 miles distant, being threatened with encroachment by the Indus. Among the antiquities round which the new town has grown up are the tomb and mosque of a piri or saint, who died in the 16th century, and in whose honour a fair, largely attended by Mahomedans from all parts of the province, is held twice a year. The local trade, chiefly of grain, piece goods, *ghis*, cotton, and sugar, is valued approximately at £89000. The transit trade (in the same articles) at about £700. Population (1872), 4096, including 2646 Mahomedans and 1234 Hindus.

HALAS, a corporate town of Hungary, in the meze or country of Pest-Pilis Solt Kis-Kun, is situated about 78 miles S S E from Budapest, in 46° 34' N lat and 19° 31' E long.

The most noteworthy buildings are the Calvinist and Roman Catholic churches, and the Jewish synagogue. Halas contains also a Protestant gymnasium, various literary institutions, and a local tribunal. The inhabitants of the town and neighbourhood are mostly engaged in cattle-breeding and agricultural pursuits. Not far from Halas is a lake of the same name, containing an island which was once fortified, and served as a place of refuge to the inhabitants from the incursions of the Turks. Prior to 1876 Halas belonged to the old district of Little Cumania. In the spring of 1879 the town was much injured by floods. The population in 1870 amounted to 13,127, of whom the greater number were Magyars.

HALBERSTADT, the chief town of a circle in the government district of Magdeburg, Prussian province of Saxony, is situated in a beautiful and fertile country on the Holzeme, a tributary of the Elbe, and at the junction point of four railways, 20 miles SW of Magdeburg. It has an antique appearance, and in a large number of the buildings the mediæval wood architecture is still preserved. About a mile and a half distant from Halberstadt are the *Spiegelberg Berge*, from which there is obtained a fine view of the surrounding country. The town possesses a cathedral in the Pointed style, dating from the 13th and 14th centuries, and restored between 1830 and 1871, containing a rich Gothic screen at the date of 1510, other interesting antiquities, beautiful glass windows, and several valuable paintings. Of the remaining churches the only one of special interest is the *Liebfrauenkirche*, a basilica in the later Romanesque style, dating from the 12th and 13th centuries, and restored in 1848, containing noteworthy wall paintings and figures in relief. Among the other old buildings may be mentioned the town-house, dating from the 11th century and restored in the 17th century, the town hall crypt, dating from the 15th century, and the Petershof, formerly the residence of the bishop, but now used as a custom house. The principal educational establishments are the gymnasium—the new buildings for which were opened in 1875—with a library of 80,000 volumes, the real school of the first order, the normal school, connected with which there is a deaf and dumb institute, and the provincial trade school. Near the cathedral is a building called the temple of friendship which contains a collection of the portraits of the friends of the poet Gleim, who was a resident in the town, and whose house was the resort of a large circle of poets and scholars. In the same neighbourhood a beautiful monument in the Early Pointed style has been erected to the memory of those who fell in the late Franco-German war. The principal manufactures of the town are linen and woollen cloth, leather, paper, gloves, waxing, cigars, soap, oil, sugar, chemical products, brandy, and liquors. The population in 1875 was 27,757.

Halberstadt owes its origin to the foundation in the 8th century of the bishopric of which it became the seat. It received town rights from Bishop Arnulf in 998. It was burnt down in 1218 by the emperor Henry V., and in 1279 by Henry the Lion. At the peace of Westphalia in 1648 the bishopric was united as a principality to Brandenburg. At the Tilist peace in 1807 it was joined to Westphalia, but in 1813 it again came into the possession of Prussia. See *Litman, Die Zeit zu Halberstadt*, 1857; *Wegmann durch Halberstadt*, 2d edition 1866, and *Die Geschichte der Stadt Halberstadt*, 1872; Scheffle, *Neuzeitliche und Legenden Halberstadter Dichter*, 1884; Schmidt, *Die Geschichte der Stadt Halberstadt*, Halle, 1878.

HALBERT, HALBERD (French, *Halb-épée*), a weapon consisting of an axe blade balanced by a pick and having an elongated pike-head at the end of the staff, which was usually about 5 or 6 feet in length. Various derivations have been suggested for the term, but M. Demmin seems to

have hit the right one in the German *Halbbothe* "half battle axe." The earliest halberds represented in the miniatures of the 14th century, or preserved in the collections of Switzerland and Germany, have the axe-blade often prolonged beyond the end of the staff, and thus resemble the English bill of the 15th century. Fauchet, in his *Origines des Dignités*, printed in 1600, states that Louis XI of France ordered certain new weapons of war called *halles bardes* to be made at Angers and other places in 1475. The Swiss had a mixed armament of pikes and halberds at the battle of Morat in 1476. We find the same mixture of billmen and halbardiers in the English army at the same time. In the 15th and 16th centuries the halberds became period. In the 15th and 16th centuries the halberds became large, and the blades were formed in many varieties of shape, often engraved, inscribed, or pierced in open work, and exquisitely finished as works of art. This weapon was in use in England from the reign of Henry VII to the reign of George III, when it was still carried by sergeants in the guards and other infantry regiments. It is still retained as the symbol of authority borne before the magistrates on public occasions in some of the burghs of Scotland. The Lochaber axe may be called a species of halberd furnished with a hook on the end of the staff at the back of the blade.

HALDANE, JAMES ALEXANDER (1768–1851), whose distinguished labours in the cause of religion have secured for him an honourable place in the ecclesiastical history of Scotland, was the younger son of Captain James Haldane of Glenlesg, Perthshire, and was born at Dundee on July 14, 1768. Educated first at Dundee and afterwards at the High School and university of Edinburgh, he shortly after the completion of his sixteenth year entered the service for which he had been from his childhood destined, by joining the "Duke of Montrose" East India-man as a midshipman. After four voyages to India he in the summer of 1793 was nominated to the command of the "Melville Castle", but having, during a long and unexpected detention of his ship, begun a careful study of the Bible, he came under deep religious impressions and, somewhat abruptly resolving to quit the naval profession, returned to Scotland before his ship had sailed. About the year 1796 he became acquainted with the celebrated evangelical divine, Simon of Cambridge, in whose society he made through Scotland more than one tour, in the course of which he endeavoured by tract-distribution and other means to awaken others to somewhat of that interest in religious subjects which he himself so strongly felt. In May 1797 he preached, at Gilmerton near Edinburgh, his first sermon with a success which was considered to be very encouraging, and during the next few years he made repeated missionary journeys, preaching wherever he could obtain hearers, and generally in the open air. Not originally dialogal to the Church of Scotland, he was gradually driven by the hostility of the Assembly and the exigencies of his position into a separatist attitude, and in 1799 he was ordained on the principles of Independency as pastor of a large congregation in Edinburgh, to which he continued gratuitously to minister for more than fifty years, and in 1808 he made public avowal of his conversion to Baptist views. As advancing years compelled him to withdraw from the more exhausting labours of itinerancy and open-air preaching, he sought more and more to influence the discussion of current religious and theological questions by means of the press, and by numerous pamphlets took part in the controversies connected with the names of Edward Irving, Erskine of Linlithgow, Campbell of Bow, and others. His latest works were a treatise on the *Doctrine of the Atonement* (1845) and an *Exposition of the Epistle to the Galatians* (1848). He died on the 8th of February 1851.

HALDANE, ROBERT (1764–1842), elder brother of the preceding, and intimately associated with him in many of his labours, was born in London on February 28, 1764. After attending classes in the Dundee grammar school and in the High School and university of Edinburgh he in 1780 joined H. M. S. "Monarch," of which his uncle Lord Duncan was at that time in command, and in the following year was transferred to the "Foudroyant," on board of which, during the night engagement with the "Pégase," he distinguished himself so much that Captain Jervis (afterwards Lord St Vincent) wrote to Admiral Duncan predicting a brilliant future for his nephew. Haldane was afterwards present at the relief of Gibraltar, but at the peace of 1783 he finally left the navy, and soon afterwards settled on his estate of Airthrey, near Stirling. The earlier phases of the French Revolution as they occurred attracted his attention and at first excited his deepest sympathy, a sympathy which induced him, at the cost of making many enemies, to avow his strong disapproval of the war with France. As his bright and over sanguine visions of a new order of things to be ushered in by political change disappeared, he, unlike Wordsworth's "Solitary," began to direct his thoughts to religious subjects, and underwent a spiritual change which, while neither sudden nor violent, was decisive and complete. Resolving to devote himself and his means wholly to the advancement of Christianity, his first proposal for that end, made in 1796, was to organize a vast mission to Bengal, of which he was to provide the entire expense, with this view the greater part of his estate was sold, but after every arrangement had been well nigh completed, the East India Company refused to sanction the scheme, which therefore had to be reluctantly abandoned. In December 1797 he joined his brother and some others in the formation of the "Society for the Propagation of the Gospel at Home", and in building chapels or "tabernacles" for its congregations, in supporting its missionaries, and in maintaining institutions for the education of young men to carry on its work, he in the course of the twelve years which followed is stated on good authority to have expended upwards of £70,000. In 1816 he visited the Continent, and first at Geneva and afterwards in Montauban (1817) occupied himself in lecturing with surprising success to theological students, among whom were Malan, Monod, and Mele D'Aubigné. Returning to Scotland in 1819, he lived partly on his estate of Auchengrey and partly in Edinburgh, and like his brother took an active part, chiefly through the press, in many of the religious controversies of the time. He died on the 12th of December 1842.

In 1816 he published a work on the *Evidence and Authority of Divine Revelation*, and in 1819 the substance of his theological propositions in a *Commentaire sur l'Épître aux Romains*. Among his later writings, besides numerous pamphlets on what was known as "the Apocryphal controversy" and on the ribbitt-wan question, are a treatise *On the Inspiration of Scripture* (1828), which he passed through seven editions, and a later *Disquisition on the Epistle to the Romans* (1836), which has been frequently reprinted, and has been translated into French and German. See *Memoirs of R. and J. A. Haldane*, by Alexander Halliday (1862).

HALE, SIR MATTHEW (1609–1676), chief-justice of England, was born on November 1, 1609, at Alderley in Gloucestershire, where his father, a retired barrister, had a small estate. His paternal grandfather was a rich clothier of Wotton-under-Edge, on his mother's side he was connected with the noble family of the Poyntzes of Acton. Both his parents having died before he was five years old, the future chief-justice was placed by his guardian under the care of Mr. Staunton, vicar of Wotton-under-Edge, through whose influence he became strongly imbued with puritanical principles. There he remained till he attained his sixteenth year, when he entered Magdalen Hall, Oxford, under the tuition of the puritanical but learned Obadiah Sedgwick. At Oxford Hale devoted himself for several

terms to the study of Aristotle and Calvin with a view to holy orders, and manifested that steadiness and application which in after years secured his reputation and advancement. But suddenly there came a change. The diligent student, at first attracted by a company of strolling players, thence aside his studies, and plunged carelessly into gay society. He soon decided to change his profession, and resolved to trail a pike as a soldier under the prince of Orange in the Low Countries. Before going abroad, however, Hale found himself obliged to proceed to London in order to give instructions for his defence in a legal action which threatened to deprive him of his patrimony. His leading counsel was the celebrated Sergeant Glanville, who, perceiving in the acuteness and sagacity of his youthful client a peculiar fitness for the legal profession, succeeded, with much difficulty, in inducing him to renounce his military for a legal career, and on the 8th November 1629 Hale became a member of the honourable society of Lincoln's Inn.

He immediately resumed his habits of intense application. The rules which he laid down for himself, and which are still extant in his handwriting, prescribe sixteen hours a day of close application, and prove, not only the great mental power, but also the extraordinary physical strength he must have possessed, and for which indeed, during his residence at the university, he had been remarkable. During the period allotted to his preliminary studies, he read over, and over again all the year-books, reports, and law treatises in print, and at the Tower of London and other antiquarian repositories examined and carefully studied the records from the foundation of the English monarchy down to his own time. Even the common-place book which he composed as the result of his study and research may, according to Lord Campbell, "be considered a *corpus juris* embracing and methodizing all that an English lawyer on any emergency could desire to know." But Hale did not confine himself to law. He dedicated no small portion of his time to the study of pure mathematics, to investigations in physics and chemistry, and even to anatomy and architecture, and there can be no doubt that this varied learning enhanced considerably the value of many of his judicial decisions.

Hale was called to the bar in 1637, and almost at once found himself in full practice. Though neither a fluent speaker nor bold pleader, in a very few years he was at the head of his profession. He entered public life at perhaps the most critical period of English history. Two parties were contending in the state, and their obstinacy could not fail to produce a most cruel collision. But amidst the confusion Hale stepped a middle course, rising in reputation, and an object of acclamation from both parties. Taking Pomponius Atticus as his political model, he was persuaded that a man, a lawyer, and a judge could best serve his country and benefit his countrymen by holding aloof from partisanship and its violent prejudices, which are so apt to distort and confuse the judgment. But he is best vindicated from the charges of selfishness and cowardice by the thoughts and meditations contained in his private diaries and papers, where the purity and honour of his motives are clearly seen. It has been said, but without certainty, that Hale was engaged as counsel for the earl of Strafford, he certainly acted for Archbishop Laud, Lord Maguire, Christopher Love, the duke of Hamilton, and others. It is also said that he was ready to plead on the side of Charles I. had that monarch submitted to the court. The parliament having gained the ascendancy, Hale signed the Solemn League and Covenant, and was a member of the famous Assembly of Divines at Westminster in 1644, but although he would undoubtedly have preferred a Presbyterian form of church government, he had

no serious objection to the system of modified Episcopacy proposed by Usher. Consistently with his desire to remain neutral, Hale took the engagement to the Commonwealth as he had done to the king, and in 1653, already sergeant, he became a judge in the Court of Common Pleas. Two years afterwards he sat in Cromwell's parliament as one of the members for Gloucestershire. After the death of the Protector, however, he declined to act as a judge under Richard Cromwell, although he represented Oxford in Richard's parliament. At the Restoration in 1660 Hale was very graciously received by Charles II, and in the same year was appointed chief baion of the exchequer, and accepted, with extreme reluctance, the honour of knighthood. After holding the office of chief baion for eleven years he was raised to the higher dignity of lord chief justice, which he held till February 1670, when his failing health compelled him to resign. He stayed to his native Alderley, where he died on December 25th of the same year. He was twice married, and survived all his ten children save two.

As a judge, Sir Matthew Hale discharged his duties with resolute independence and careful diligence. Lord Campbell says of him that "he is certainly to be considered the most eminent judge who ever filled the office [of chief baion], and being promoted to be chief justice of England, he gave new dignity to the supreme magistracy which had been illustrated by Gressens, by Fortescue, and by Coke." His sincere piety made him the intimate friend of Barrow, Tillotson, Wilkins, and Stillingfleet; as well as of the Non-conformist leader Dyer. He is chargeable, however, with the condemnation and execution of two poor women used before him for witchcraft in 1604, a kind of judicial murder then falling under dispute. He is also reproached with having hastened the execution of a soldier for whom he had reason to believe a pardon was preparing.

Of Hale's legal works the only two of importance are his *Reasons in Pleas in Corona*, or *History of the Pleas of the Crown*, first published in 1739, and the *History of the Common Law of England*, with an *Analysis of the Law*, &c., 1713. Among his numerous religious writings the *Contemplations, Moral and Divine*, occupy the first place. Others are *The Primitive Origination of Man*, 1677, *Of the Nature of True Religion*, &c., 1684, *A Brief Abstract of the Christian Religion*, 1689. One of his most popular works is the collection of *Letters of Advice to his Children and Grandchildren*. He also wrote an *Essay touching the Creation and Nongeneration of Fixed Bodies*, 1678, *Difficultes Nuge, or Observations touching the Jurisdictional Experiment*, &c., 1675, and a translation of the *Life of Pompeius Africanus*, by Cornelius Nepos. His efforts in poetry were innumerable. He left his valuable collection of MSS and records to the library of Lincoln's Inn. His life has been written by Benet, 1682, by Williams, 1836, by Boswell, in his *Lives of Eminent Lawyers*, in 1859, and by Lord Campbell, in his *Lives of the Chief Justices*, in 1849.

HALES, STEPHEN (1677–1761), physiologist and inventor, was born at Beckenham in Kent, on the 7th September 1677. He was the sixth son of Thomas Hales, whose father, Sir Robert Hales, was created baronet by Charles II in 1670. Of his early education little is known, but in June 1696 he was entered as a pensioner of Denb' (now Corpus Christi) College, Cambridge, with the view of taking holy orders. On 16th April 1702 he was elected and in February 1703 admitted to a fellowship. He received the degree of master of arts in 1703, and of bachelor of divinity in 1711. While at college one of his most intimate friends was William Stukeley, with whom he studied anatomy, chemistry, &c. In 1710 Hales was presented to the perpetual curacy of Teddington in Middlesex, where he remained all his life, notwithstanding that he was subsequently appointed rector of Pollock in Somerset, and later of Faringdon in Hampshire. In March 1717 he was elected fellow of the Royal Society, to whose *Transactions* he contributed many valuable papers. In 1733 he was named one of a committee for establishing

a colony in Georgia, and the next year he received the degree of doctor of divinity. He was appointed almoner to the pincheon dowager of Wales in 1760. On the death of Sir Hans Sloane in 1753, Hales was chosen foreign associate of the French Academy of Sciences. He died at Teddington, January 4, 1761.

Hales is celebrated as the inventor of a "ventilator," by means of which fresh air was introduced into jails, hospitals, mines, ships' holds, &c. In the four years (1749–53) after its introduction into the Savoy prison, only 4 prisoners died, while previously the mortality had been from 60 to 100 per annum. The invention met with immediate favour, especially in France. Hales was the designer of other inventions by means of which sea water was distilled, coal cleaned and preserved, meat preserved on long voyages, &c.

His chief writings are his *Statistical Essays* (see CHEMISTRY, vol v p 461), consisting of *Vegetable Statics*, or an Account of some Statical Experiments on the Sap in Vegetables (1727), and *Hemostatics*, or an Account of Symplic and Symplic Statical Experiments made on the Blood and Blood vessels of Animals (1738). His essay on *The Means of Dissolving the Stone in the Bladder*, &c., gained him the Copley gold medal in 1737. His *Advertisement to the Doctors of Giv, Stroud, &c.*, appeared in 1738, the *Vegetable Statics*, translated by Buffon, in 1758, and the *Haemostatics*, by M. de Sauvages, in 1744. For sketch of his life, with portrait, see *Gedden's Chronicle*, 1877, pp 30–37.

HALEVY, JACQUES FRANÇOIS FOMENTAL (1790–1862), a celebrated French musician, was born May 27, 1790, at Paris. He studied at the Paris Conservatoire under Berton and Cheuubert, and in 1819 gained the grand prix de Rome with a cantata called *Le Manne*. In accordance with the conditions of his scholarship he started for Rome, where he devoted himself to the study of Italian music, and wrote an opera and various minor works. His first opera produced in Paris after his return from Italy was called *L'Africain*, which saw the light at the Théâtre Feytaud in 1827, apparently without much success. Other works of minor importance, and now forgotten, followed, amongst which only a ballet named *Hanon Lescarot*, produced in 1830, deserves mention. Five years later, in 1835, HALEVY produced the tragic opera *La Juive* and the comic opera *L'Eclair*, and on these works his immortality is mainly founded. Both have kept the stage to the present day, and will probably survive changes of taste even greater than those which music has undergone in France during the last forty years. *The Jewess* is in every way representative of the French *grand-opéra*, the modern outgrowth of Gluck's music-drama with a strong admixture of the Italian element and of an excess of spectacular splendour wholly strange to the classic simplicity of the original. It is curious that the *grand-opéra*, although an essentially national product of France, was both imitated and brought to its highest perfection by two Germans—Gluck and Meyerbeer. The genius of the latter was fatal to HALEVY's fame. By the side of the *Huguenots* the merits of *La Juive* appear in almost diminutive proportions. At the same time HALEVY's work ought not to be treated with contempt. It is full of fine dramatic features, and especially the introduction of the Jewish element—with which HALEVY, himself a Jew, was well acquainted—gives a peculiar interest on this score. *L'Eclair* is a curiously of musical literature. It is written for two tenors and two soprano, without a chorus, and displays the composer's mastery over the most refined effects of instrumentation and vocalization in a favourable light. After these two works, to which HALEVY owed his fame and his seat at the Institute, he wrote numerous operas of various genres, amongst which only *La Reine de Chypre*, a spectacle piece analysed by Wagner in one of his Paris letters (1841), and *La Tempesta*, in 3 acts, written for Her Majesty's Theatre, London (1850), need be referred to. In addition to his

productive work Halévy also rendered valuable services as a teacher. He was professor at the Conservatoire from 1837 till his death—some of the most successful amongst the younger composers in France, such as Gounod, Victor Massé, and Georges Bizet, the author of *Queen*, being amongst his pupils. Halévy also tried his hand at literature, and there exists an agreeable volume of *Souvenirs et Portraits* from his pen. He died at Nice, March 17, 1863.

HALIBURTON, THOMAS CHANDLER (1796–1865), long a judge of Nova Scotia, and a popular literary satirist, was born at Windsor, Nova Scotia, in 1796, and received his education there, at King's College. He was called to the bar in 1820, and took part in the legislature of his native province as a member of the House of Assembly. He distinguished himself as a barrister, and in 1828 was promoted to the bench as a chief-justice of the common pleas. But it is as the brilliant humorist and satirist that he is now remembered, for his labours alike as a barrister and a member of parliament were limited to his own province, and could scarcely beget anything beyond a local reputation. Yet confined as he thus was to so narrow a sphere, a true estimate of its disadvantages is necessary in order to do justice to the vigorous individuality of his writings. He was a native of what was then a small and isolated maritime province, detached from Canada. Its exports consisted chiefly of lumber and the produce of its fisheries, and with these trade was carried on with Great Britain, the West Indies, and the United States. Its entire population at the time when Haliburton was called to the bar, including Indians, African refugees from the States, and the Acadian descendants of the original French population, did not amount to 97,000. The English settlers were largely composed of refugees from the former British colonies, animated by the strong Conservative sympathies of the old colonial loyalists. The French Acadians were Roman Catholics, and their national traditions and religion equally tended to alienate them from the neighbouring republic.

In politics Haliburton adhered through life to the Conservative party, and the influence of his early associations is traceable in most of his writings. He was still at the bar when he wrote *An Historical and Statistical Account of Nova Scotia*, in 2 vols. Canada, it will be remembered, then consisted of Upper and Lower Canada only, and with the French population of the latter and nearer province, was even stranger to the Nova Scotian than the New England States. The lessons which judicial duties secured admitted of literary relaxations in which Judge Haliburton's fine sense of the humorous had free play, and in 1835 he contributed anonymously to a local paper a series of letters professedly depicting the peculiarities of the genuine Yankee. These sketches, which abounded in clever pictures of national and individual characters, drawn with great satirical humour, were collected in 1837, and published under the title of *The Clockmaker, or Sayings and Doings of Samuel Stock of Stockville*. A second series followed in 1838, and a third in 1840. *The Atlantic, or Sam Stock in England* (2 vols 8vo), was the result of a visit there in 1811. This also was followed up by a second series in 1844. His other works include—*The Old Judge, or Life in a Colony*, *The Letter Bag of the Great Western Rule and Man of the English in America*, *Tracts of American Humour, and Native and Humour Notes*.

While the judge was thus diligent in his literary recreations, he continued to secure popular esteem in his judicial capacity. In 1840 he was promoted to be a judge of the supreme court, but within two years he resigned his seat on the bench, removed to England, and after a time entered parliament as the representative of Launceston, in the Conservative interest. His literary reputation awoke expecta-

tions which were not fulfilled. The bar has rarely proved to be an apt school for training the parliamentary debater, and he was too far advanced in life to adapt himself to the novel requirements of the English House of Commons. The last time he spoke he was listened to with interest on the Canadian defence. But the tenure of his seat for Launceston was brought to an end by the dissolution of the parliament in 1865, and he did not again offer himself to the constituency. His death followed in the month of August of the same year, at Gordon House, Isleworth, when he was in his seventieth year.¹

HALIBUT. See HOLMUT.

HALICARNASSUS, an ancient Greek city on the south-western coast of Asia Minor, built on a picturesque and advantageous site at the northern end of the Ceramic Gulf or Gulf of Cos. It originally occupied only the small island of Zephyria, close to the shore, but in course of time this island was united to the mainland and the city extended so as to incorporate Halimae, an older town of the Leleges and Carians. About the foundation of Halicarnassus various traditions were current, but they agree in the main point as to its being a Dorian colony, and the figures on its coins, such as the head of Medusa or Minerva, the head of Neptune, or the trident, give support to the statement that the mother cities were Troezen and Argos. The inhabitants appear to have accepted as the legendary founder Anthos, mentioned by Strabo, and were proud of the title of Antiochians. At an early period Halicarnassus was a member of the Dorian Hexapolis, which include Cos, Chios, Lindus, Camirus, and Lysius, but one of the citizens, Agaracles, having taken home the prize tripod which he had won in the Troian games instead of dedicating it according to custom to the Troian Apollo, the city was cut off from the league. In the time of Xerxes we find Halicarnassus under the sway of a certain Artemisia, who made herself famous by the assistance she rendered to the great Persian invader. Pigeus, her brother or son, was the reputed author of the *Batrachomyomachia*. Of Pisindelus, her son and successor in the sovereignty, little is known, but Lygdamis, who next attained to power, is notorious for having put to death the poet Panyassis and caused Herodotus, the greatest of the Halicarnassians, to leave his native city (c. 457 B.C.). About the close of the 5th century B.C. the power of Athens became predominant over Halicarnassus and other Dorian cities of Asia, but the peace of Antalcidas in 387 made them subservient to Persia, and it was under Mausolus, a Persian satrap of almost independent authority, that Halicarnassus attained its highest prosperity. Struck by the natural strength and beauty of its position, Mausolus removed thither from Mylasa, and increasing its population by the inhabitants of six towns of the Leleges, devoted himself to its embellishment and defence. On his death he was succeeded by his widow and sister, Artemisia, whose military ability was shown by the stratagem by which she captured the Rhodian vessels attacking his city, and whose magnificence and taste have been perpetuated to all time by the "Mausoleum," the monument she erected to her husband's memory. In the execution of this wonderful enterprise she employed the architects Satyrus and Pythius.

¹ Judge Haliburton was descended from the branch of the Newmans and Minton family which figures in the genealogical memoirs of the Haliburtons in their relation to that of St. Waltes Stock, whose paternal grandmother was Elizabeth Haliburton. The note of all the families of the name flows up by the father of the poet and novelist was prepared in reply to inquiries of the father of Judge Haliburton, with a view to the establishment of his claims to certain family property. Of a younger branch of the Newmans family that went to Jamaica, one member removed to Massachusetts. A son of his, the father of the judge, migrated to Nova Scotia, and there, in 1769, he revived old hereditary rights, and reclaimed relationship with the original Scottish stock.

and the sculptors Scopas, Learchus, Bryaxis, and Timotheus; and though she died before the completion, she continued it with all the enthusiasm of an artist. In the history of Hali-carassus the next important events were connected with the conquests of Alexander the Great. Memnon, satrap of the west coast, having taken refuge within its walls after the battle of Granicus, it was besieged by the Macedonians, captured, and plundered. Not long afterwards we find the citizens receiving the present of a gymnasium from Ptolemy, and building in his honour a stoa, or portico; but the city never recovered altogether from the disasters of the siege, and Cicero describes it as almost deserted. The site is now occupied by the town of Budrum, but the ancient walls can still be traced in nearly all their circuit, and the position of several of the temples and public buildings can be fixed with considerable certainty.

From the ruins of the Mausoleum sufficient has been recovered by the excavations carried out in 1857 by C. T. Newton to enable a fairly complete restoration of its design. According to Mr Pullan, Mr Newton's collaborator, the building consisted of five parts: a basement or podium, a pteron or enclosure of columns, a pyramid and pedestal, and a chariot group. The basement, probably 51 feet in height, and covering an area of 114 feet by 92, was built of blocks of granitic stone and faced with marble, the masonry of the pteron being possibly broken by one or more belts of frieze. The pteron, 37½ feet in height, consisted (according to Pliny) of thirty-six columns of the Ionic order, enclosing a square cella, the walls of which were relieved by friezes. From the portions that have been recovered it appears that the principal frieze of the pteron represented combats of Greeks and Amazons. "Throughout," says Mr Newton, "there is a skilful opposition of male and draped male and female forms; but the groups and figures are much less intellectual than in the Parthenon and Phigalian friezes. The whole surface was coloured, the ground of the relief being ultramarine and the flesh a dull red, while the drapery and armour were picked out with various hues." Fragments have been found of two other friezes of doubtful position in the monument, one representing a chariot race and the other a centaur fight. Above the pteron rose the pyramid, approximately 108 feet long and 88 feet wide at the base, and mounting by 24 steps to an apex or pedestal, which possibly had a length of 26 feet 6 inches and a breadth of 20 feet. On this apex stood the quadriga or chariot with the figure of Mausoleus himself and an attendant deity acting as his charioteer. The height of the statue of Mausoleus—it has happily been preserved and forms part of the treasures of the British Museum—is 6 feet 8½ inches without the plinth. The hair rising from the forehead falls in thick waves on each side of the face and descends nearly to the shoulder; the beard is short and close, the face square and massive, the eyes deep set under overhanging brows, the mouth well formed with settled calm about the lips. The drapery, consisting of a cliton and mantle, is grandly composed. Such are the main features of the great Mausoleum which deservedly ranked among the wonders of the world. The minor edifices and sculptural remains of Hali-carassus are of secondary moment. Of well-preserved inscriptions the number is comparatively few; but one or two (such as that containing the names of Lygdamis and Tanyasis) are of no small interest to the archaeologist.

For further details see Rose, *Notes and Plans of the Mausoleum at Halicarnassus*; Hamilton's *Researches in Asia Minor*; and Newton's *History of Discoveries at Halicarnassus*, 1858-9, and his *Principles of the Art*, 1860.

HALIFAX, a municipal and parliamentary borough and market-town of England, in the northern division of the West Riding of Yorkshire, is situated on a gentle acclivity almost surrounded by hills, on the small river Hebble near its junction with the Oulder, 7 miles south-west of Bradford. Originally its streets were narrow and irregular, but many of the older houses have been pulled down and new streets opened up, while the constant additions made to it through the rapid increase of population have completely changed its appearance. The principal buildings are the parish church of St John, the restoration of which was completed in 1879 at a cost of £16,000, a structure in the Perpendicular style, of different dates, and having the western tower 117 feet in height; All Souls Church, begun in 1859 from the designs of Sir Gilbert Scott, and erected at the expense of Mr Edward Akroyd, in the Early Decorated style, very richly ornamented with statues and carvings in Italian marble, serpentine, and alabaster, and consisting of nave, aisles, transepts, and chancel, with a very graceful tower and spire

at the north-west angle 236 feet in height, and a sacristy at the north-east; the Square Church, erected by the Congregationalists in 1857 at a cost of £16,000, an ornate cruciform building with a tower and elaborate crocketed spire rising to a height of 235 feet; the town-hall, completed in 1863 after the designs of Sir Charles Barry at a cost of £40,000; the infirmary, a large and elegant building in which medical and surgical aid is afforded to outdoor as well as indoor patients; the Waterhouse charity school, a handsome set of buildings forming three sides of a quadrangle, erected in 1855; the Crossley almshouses, erected and endowed by Sir Francis and Mr Joseph Crossley; the piece-hall, a large quadrangular structure more than 2 acres of ground, erected in 1799 for the lodgment and sale of piece goods, but now used as a market for fish and vegetables; the free grammar school, founded in 1585 under royal charter for instruction in the classical languages; the Crossley orphan home and school, built by the Crossley

Plan of Halifax.

brothers at a cost of £48,000; the museum, the oldfellows' hall, the working men's college, the mechanics' institute, the assembly and concert rooms, and the theatre. There are three public parks, viz., Savile Park, 50 acres in extent; the People's Park, 12½ acres, laid out in a highly ornamental style from the designs of Sir Joseph Paxton, and presented to the town in 1855 by Sir Francis Crossley; and the Shrogg's Park, 25 acres, opened in 1877. The North Bridge, a fine structure of iron, spans the Hebble valley in two arches. Halifax derives its importance from its manufactures of cloth, which began in the 15th century. It ranks in Yorkshire with Leeds, Bradford, and Huddersfield as a seat of the woollen and worsted manufacture. The principal staples are carpets, cashmeres, orleanses, coburgs, merinos, lastings, alpaca, damasks, baizes, broad and narrow cloths, korsemeres, blankets, muslin-de-laines, shalloons, and figured vestings. A considerable number of persons are employed in iron-works, machine works, and chemical works, and in the

neighbouring coal-mines and stone quarries. The borough sends two members to parliament. The parish is the largest in Great Britain, embracing 79,300 acres. The population of the municipal and parliamentary borough in 1861 was 67,014, and in 1871 (with an extended area of 8704 acres) 65,510.

Two derivations are given for the name Halifax. According to Camden it means "holly haw," and he accounts for the origin of the name from the fact that the head of a virgin who had been murdered by a wicked clerk was suspended on a tree in the neighbourhood, which was to be much resorted to by pilgrims. According to another account, the name means "holly faye," and is derived from an image of St. John the Evangelist in a neighbouring hamlet. The first mention of the town is in the 12th century, when its church was granted by William, earl of Warren, to the priory of Leas in Sussex. When its manufactures commenced in the beginning of the 16th century the number of its houses was only 15, but they had increased in 1610 to 620. It is said to have received a considerable accession to its inhabitants and impulse to its prosperity from the merchants who fled from the Scottish exile to escape the persecution levied out under the auspices of the duke of Alva. In 1648 it was garrisoned by the forces of the parliament, and near it a place still called the Bloody Field an engagement took place between them and the royalists. In the forest of Hardwick, then extensive within the parish of Halifax, there at one time existed a grove called the "Gibbet-Law," according to which any person suspected to be in the unlawful possession of goods to the value of 10s. was tried by the first burgess of the residence of the accused, and if convicted on a market day by a kind of a scrambling the modern gullotine. The last execution took place in 1680. A number of eminent men have been born in the town or neighbourhood of Halifax, including the mathematician Henry Briggs, Archbishop Tillson, Sir Isaac Barrow, and John Foster. Daniel Defoe resided for some time in the town.

HALIFAX, a city and seaport of British North America, capital of Nova Scotia, is situated on the south east coast of the province on the declivity of a hill about 260 feet in height, rising gradually from the south-west side of Chebucto Bay or Halifax harbour, a deep inlet into the sea. The hill is commanded by a citadel about a mile in circumference and of great strength, and the harbour is defended by several forts and batteries. Originally the houses were chiefly of wood plastered or stuccoed, but the frequent recurrence of fires has led to a more general use of stone or brick as building materials. Many of them have an imposing and elegant appearance, and the streets are spacious and regularly laid out, crossing each other at right angles. Including its suburbs the city is from 2 to 3 miles long and about 1 mile broad. The principal buildings are the Government house, the offices of the governor and the lieutenant governor, of Nova Scotia, a solid sombre-looking structure at the south of the town, the provincial building near the centre of the town, 140 feet long by 70 feet broad, with a fine Ionic colonnade, and comprising the Government offices, the post-office, the city library and the provincial museum, the parliament building, the courthouse, the admiral's house, the exchange, the Roman Catholic cathedral of St. Mary, the rooms of the young men's Christian association, the Wellington barracks, the military hospital, the lunatic asylum, the workhouse, the jail, and the penitentiary. The educational establishments include the Dalhousie college and university, the St. Mary's Roman Catholic college, the Presbyterian theological college, the High School, the almshouse of industry for girls, two orphan asylums, a blind asylum, a lunatic asylum for the Lower Provinces, two industrial schools, and nearly twenty public schools. A lighthouse has been erected on the west side of the entrance to the harbour on a small island off Sambro Cape. After passing Sambro the course for large vessels is to the west of McNab's Island, on which a lighthouse has also been erected, but there is also a passage sufficient for small vessels to the east of the island. Recently a lighthouse has been erected on the west side of St. George's Island opposite the city. Halifax is the seat of a considerable fishery. Its principal trade is with

Great Britain, the British colonies, and the United States. In 1878 the number of ships that entered was 887, with a tonnage of 347,836. The value of imports was \$4,981,305, and of exports \$4,102,335. The imports are chiefly manufactures from England, manufactures and produce from the United States, and sugar, molasses, rum, and other products from the West Indies, the chief exports are dried and pickled fish, timber, cattle, agricultural and dairy produce, fur, and whale and seal oil. Halifax is now used instead of Portland in the State of Maine as the winter port (the St. Lawrence being closed with ice) for the Dominion of Canada. The principal industries of Halifax are nonferrous, brewing, distilling, sugar refining, and the manufacture of woollen and cotton goods, paper, leather, tobacco, gunpowder, agricultural and musical instruments, carriages, machinery, candles, and soap. On account of its fine air and the beautiful scenery of the neighbourhood, Halifax has a high reputation as a watering-place. An abundant supply of water for the city is obtained from two lakes 2 miles distant. The city is the seat of an Anglican bishop and a Roman Catholic archbishop. Nearly one-third of the population is Roman Catholic. It is named after the earl of Halifax, and was founded by Governor Cornwallis in 1749. In 1700 it contained only 700 houses and 4000 inhabitants. It was declared a free port in 1817, at which time the number of houses was 1200. The population in 1861 was 25,026, and in 1871, 29,582.

HALIFAX, CHARLES MONTAGUE, EARL OF (1661-1716), English statesman and poet, fourth son of the Honorable George Montague, who was fifth son of the first earl of Manchester, was born at Ilton, Northamptonshire, on the 16th April 1661. In his fourteenth year he was sent to Westminster school, where he was chosen king's scholar in 1677, and distinguished himself in the composition of extempore epigrams made according to custom upon those appointed for king's scholars at the time of election. In 1682 he entered Trinity College, Cambridge, where he acquired a solid knowledge of the classics and surpassed all his contemporaries at the university in logic and ethics. Latterly, however, he preferred to the abstractions of Descartes the practical philosophy of Sir Isaac Newton, and he was one of the small band of students who assisted Newton in forming the Philosophical Society of Cambridge. But it was his facility in prose-writing, and neither his scholarship nor his practical acuity that first opened up to him the way to fortune. His clever, but absurdly panegyric poem on the death of Charles II., which was published in the *Book of Condolences and Congratulation* presented by the university to James II., secured for him the notice of the earl of Dorset, who invited him to town and introduced him to the principal wits of the time, and in 1687 his joint authorship with Prior of the *Town and Country Mouse*, a happy parody of Dryden's *Hand and Panther*, not only increased his literary reputation but directly helped him to political influence. In 1688, through the patronage of the earl of Dorset, he entered parliament as member for Malden, and sat in the convention which resolved that William and Mary should be declared king and queen of England. About this time he married the countess dowager of Manchester, and it would appear, according to Johnson, that it was still his intention to take orders, but after the coronation he purchased a clerkship to the council. On being introduced by Earl Dorset to King William, after the publication of his poetical *Epistles occasioned by his Majesty's Victory in Ireland*, he was ordered to receive an immediate pension of £500 per annum, until an opportunity should present itself of "making a man of him." In 1691 he was chosen chairman of the committee of the House of Commons appointed to confer with a committee of the Lords in regard to the Bill for regulating trials in cases of

high treason, and he displayed in these conferences such tact and debiting power that he was made one of the commissioners of the treasury and called to the privy council. It was during these debates that he had recourse to the peculiar oratorical device of losing his presence of mind, in order to give a practical illustration of the necessity of allowing the privilege of counsel to criminals before a court of justice. But his success as a politician was less due to his oratorical gifts than to his skill in finance, and in this respect he soon began to manifest such brilliant talents as completely eclipsed the painstaking abilities of Godolphin. Indeed it may be affirmed that no other statesman has initiated schemes which have left a more permanent mark on the financial history of England. Although perhaps it was inevitable that England should sooner or later adopt the Continental custom of lightening the annual taxation in times of war by contracting a national debt, the actual introduction of the expedient was due to Montague, who on the 15th December 1692 proposed to raise a million of money by way of loan. Previous to this a Scotchman named William Paterson had submitted to the Government his plan of a national bank, and when in the spring of 1694 the prolonged contest with France had rendered another large loan absolutely necessary, Montague introduced a Bill for the incorporation of the Bank of England. The bill after some opposition passed the House of Lords in May, and immediately after the prorogation of parliament Montague was rewarded by the chancellorship of the exchequer. In the following year he was triumphantly returned for the borough of Westminster to the new parliament, and succeeded in passing his celebrated measure to remedy the depreciation which had taken place in the currency on account of dishonest manipulations. To provide for the expense of recoinage, Montague, instead of reviving the old tax of hearth money, introduced the window tax, and the difficulties caused by the temporary absence of a metallic currency were avoided by the issue for the first time of overleaves bills. His other expedients for meeting the emergencies of the financial crisis were equally successful, and the rapid restoration of public credit secured him a commanding influence both in the House of Commons and at the board of the treasury, but although Godolphin resigned office in October 1696, the king hesitated for some time between Montague and Sir Stephen Fox as his successor, and it was not till 1697 that the former was appointed first lord. In 1698 and 1699 he acted as one of the council of regency during the king's absence from England. When in February of the former year he had been accused of peculation in connection with the issue of exchequer bills, not only had he been triumphantly acquitted but the House had declared that for his good services to the Government he had deserved his Majesty's favour, and his reputation was still further increased in the same year by the extraordinary popularity of his project for a new East India Company. With the accumulation of his political successes his vanity and arrogance became, however, so offensive that lately they utterly lost him the influence he had acquired by his administrative ability and his masterly eloquence, and when his power began to be on the wane he set the seal to his political overthrow by confiding the lucrative sinecure office of auditor of the exchequer on his brother-in-law. For some time after this he was compelled to retire from power. For some time after this in attempting to lead the House of Commons he had to submit to constant mortifications, often verging on personal insults, and after the return of the king in 1699 he resigned his offices in the Government and succeeded his brother in the auditorship. On the accession of the Tories to power he was removed in 1701 to the House of Lords by the title of Lord Halifax. In the same year he was impeached for

malpractices along with Lord Somers and the seals of Portland and Orford, but all the charges were dismissed by the Lords, and in 1703 a second attempt to impeach him was still more unsuccessful. He continued out of office during the reign of Queen Anne, but in 1706 he was named one of the commissioners to negotiate the union with Scotland, and after the passing of the Act of Settlement in favour of the house of Hanover, he was appointed ambassador to the elector's court to convey the insignia of order of the garter to George I. On the death of Anne (1714) he was appointed one of the council of regency until the arrival of the king from Hanover, and after the coronation he received the office of first lord of the treasury in the new ministry, being at the same time created Earl of Halifax and Viscount Sainsbury. He died on the 15th May of the following year, and left no issue. His nephew succeeded to the barony, and was raised to the earldom, he left it to his son George Dunk, a statesman of some eminence, with whose death without issue in 1771 the Halifax titles became extinct.

Montague's association with Prior in the travesty of Dryden's *Lind and Panther* has no doubt largely aided in preserving his literary reputation, but he is perhaps indebted for its stability to his subservient and influential position and to the fulsome flattery of the men of letters who enjoyed his friendship, and who, in return for his liberal donations and the splendid banqueting which they occasionally enjoyed at his villa on the Thames, "fed him," as Pope says, "all day long with dedications." That, however, his beneficence to needy talent, if sometimes attributable to an itching ear for adulation, was at others prompted by a sincere appreciation of intellectual merit, is sufficiently attested by the manner in which he procured from Godolphin a commissionership for Addison, and also by his lifelong intimacy with Newton, for whom he obtained the mastership of the mint. The small fragments of poetry which he left behind him, and which are almost solely the composition of his early years, display a certain facility and vigour of diction, but their thought and fancy are never more than commonplace, and not infrequently in striving to be eloquent and impressive he is only grotesquely and extravagantly absurd. In administrative talent he was the superior of all his contemporaries, and his only rival in parliamentary eloquence was Somers, but the skill with which he managed measures was superior to his tact in dealing with men, and the effect of his brilliant financial successes on his reputation was gradually almost nullified by the affected arrogance of his manner and by the eccentricities of his sensitive vanity. So eager later in life was he for fame and power that perhaps Marlborough did not exaggerate when he said that "he had no other principle but his ambition, so that he would put all in distraction rather than not gain his point."

Among the numerous notices of Halifax by contemporaries may be mentioned the eulogistic reference which concludes Addison's account of the "greatest of English poets," the dedications by Steele to the second volume of the *Spectator* and to the fourth of the *Tatler*, Pope's laudatory mention of him in the epilogue to his *Waste*, and in the preface to the *Essay*, and his portrait of him as "Full blown Bubo" in the *Epistle to Arbuthnot*. Various allusions to him are to be found in Swift's works, and in Marlborough's *Letters*. See also Burnet's *History of his Own Times*, *The Parliamentary History of England*, *His Miscellaneous Works* he was published at London in 1704, his *Life and Miscellaneous Works* in 1716, and his *Political Works*, to which also his "Life" is attached, in 1718. His poems were reprinted in the 9th volume of Johnson's *English Poets*.

HALIFAX, GEORGE SAVILE, MARQUESS OF (c. 1690-1695), English statesman and author, son of Sir William Savile, a Yorkshire baronet of ancient family, and of Anne, daughter of the Lord keeper Coventry and sister of the wife of the first earl of Shaftesbury, was born about 1690

He succeeded to the baronetcy on the death of his father, and, having taken an active part in the Restoration, he was in 1697 created Baron Savile and Viscount Halifax. Subsequently his political conduct gave deep offence to the king, but, although, on his being mentioned in 1672 for a seat in the privy council, Charles at first "kicked at the name," the necessities of the political situation induced him to yield to the solicitations of his advisers, whose arguments for the admission of Halifax were based upon "his family, his abilities, his state and credit, as well as talent to ridicule and unavail whatever he was spited at." Already he was known as one of the most brilliant orators in the House of Lords, and although his political opinions seemed to be shifting and uncertain, the fascination of his manner and his formidable talents in gradually securing him the pre-eminent favour of the king. In June 1672 he was sent to negotiate terms of peace with France, but he was kept in ignorance of the agreement between Charles and Louis in regard to the establishment of popery in England. He strenuously opposed the Test Bill introduced by Lord Danby in 1673, but continued to sit at the council board till the following year when, having provoked Lord Danby by a witicism in reference to his mild manner of refusing a bribe, the latter procured his dismissal. In 1679 he was, however, created an earl, and having become a member of the new council after the fall of Danby, he differed from the earl of Shaftesbury and his other colleagues in reference to the Exclusion Bill, and by an extraordinary manifestation of nearly all the resources of oratory was instrumental in causing its rejection by the Lords. On this account an address was presented by the Commons paying him "dismissal from the king's person and councils for ever," but the king, whose confidence he had now completely won, retained him in the council, and in 1682 he was created a marquess and became lord privy seal. Although, however, chiefly instrumental in securing the duke of York's succession, his projected limitations of James's authority when the crown should devolve upon him, as well as his subsequent leaning to Whig principles, awakened the duke's settled hostility, and thus was further deepened by his exposure of the malversation of the earl of Rochester. After the accession of James he was accordingly removed from the office of privy seal to that of president of the council, a less important position, and when in 1685 he refused to give his vote for the repeal either of the Test Act or of the Habeas Corpus Act, he was dismissed from the cabinet. But though made privy to the negotiations entered into with the prince of Orange, Halifax, notwithstanding his political humiliation, was opposed to armed intervention, and endeavoured to obtain such concessions from the king as would render this unnecessary. Even after the landing of the prince he consented to act as one of the three commissioners appointed to treat with him, and it was only the cowardly and traitorous flight of James that induced him finally to abandon his cause and to take measures for raising William to the throne. In the Convention Parliament he was chosen speaker of the Lords, and strongly opposed the motion for a regency. On the accession of William he was made lord privy seal, but the disasters of the Irish campaign gave such a plausible colour to the arguments of his opponents against his competency, and to their insinuations regarding his political honesty, that, though still retaining the office of privy seal, he in October 1689 ceased to take part in the councils of the king. He succeeded before the committee of the House of Lords in clearing himself from all guilt in connexion with the murder of Russell and Sidney, but shortly afterwards resigned his office. Irritated doubtless by the bitter animosity of the Whigs and by the coldness of William, he now at first joined himself to the opposition, and even went so far

as to hold communications with St Germains, but either because his anger had cooled, or because he had become convinced of the hopelessness of the fortunes of the Stuarts, he gradually veered back to the support of the Government. He died somewhat suddenly, 20th April 1695. He was succeeded by his son William, with whose death in 1699 the title became extinct in his family. A daughter by his second marriage was the mother of the fourth and celebrated earl of Chesterfield, and from his maternal son, Henry Casley the dramatist, was descended the celebrated Edmund Kean. Halifax is portrayed in Dryden's *Abdolon* and *Achtophzel* as—

"To them of pacifying wit and poignant thought,
Lauded by nature and by learning taught
To move assemblies."

Of his speeches not the smallest fragment remains, but it is admitted that his highest efforts far excelled in effect even those of Shaftesbury, who was his only rival. "Old men," says Macaulay, "who lived to admire the eloquence of Pulteney in its meridian and that of Pitt in its splendid dawn, still murmured that they had heard nothing like the great speeches of Lord Halifax on the Exclusion Bill." The key to the greatest part of his political conduct is to be found in the pamphlet *On the Characters of a Timidist*, of which he was undoubtedly the author. It was a timidity, but a timidity in the best sense of the term, for though not insensible to worldly advantages, and, notwithstanding his philosophical professions, a lover of pomp and external honours, he was remarkably uncontaminated by the political corruption then almost universally prevalent, and was so emancipated both from party prejudice and selfish ambition as to be able generally to guide his political course by a regard to the best interests of the nation. His sudden changes from one side in politics to another, so far from indicating a loose political morality, were in reality due to the very opposite reason, for in times so unsettled violent and dangerous oscillations were apt to result from a tendency to extremes in both parties. But though his peculiar mental constitution enabled him to play a more important and beneficial part in the politics of his time than any of his contemporaries, it unfitted him for achieving success as a minister of the crown, and rendered his political career a seeming failure. His bent was philosophical rather than practical, and, notwithstanding his great prudence and judgment in several important emergencies, he was apt to be timid and indecisive when the interests of the country hung round upon himself. His writings are neither large nor numerous, but they pure, polished, and nervous English, acute reasoning, mature if somewhat worldly wisdom, apt and varied illustration, and clever and genial wit, fairly entitle them to a place among English classics. Privately he was, according to Burnet, "a man of a great and ready wit, full of life and very pleasant, much given to satire." He had the reputation of holding atheistical opinions, but on his deathbed "professed himself a sincere Christian."

He was the author of *The Anatomy of an Equivocalist*, printed in the collection of *State Tracts*, vol. 10; *Remarks on a Essay upon Taxes, Addressed to a Dauphin*; *The Characters of a Timidist*, published anonymously; *Maxims of State applicable to all Times*; *Characters of Bishop Burnet*; *A Seasonable Address to both Houses of Parliament*; *Questions for Choice of Parliament Men*; *A Rough Draught of a New Model of Sen*; *Observations upon the Reigns of Edward I., II., III., and Richard II.*, and *A Character of Henry Charles the Second, and Politick, Moral, and Miscellaneous Thoughts and Reflections*, first published in 1720. His *American*, consisting of seven of the above pamphlets, appeared in 1700. A notice by the Hon. Hugh P. Elliot of a "New Manuscript of George Savile, first marquess of Halifax," will be found in *Hamilton's Magazine* for October 1877. He also left *Memories of his Life*, which were destroyed. See besides the histories of Hume, Fox, Langens, and Macaulay, Buch's *Lives*, Burnet's *History of his own Times*, Chesterfield's *Memories*, Walpole's *Royal and Noble Authors*, Courtenay's *Life of Sir William Temple*, and Burnet's *Anecdotes*, vol. ix.

HALL, a town in northern Tyrol, Austria, government district of Innsbruck, is picturesque situated between two mountains on the left bank of the Inn, which is navigable there, and on the railway from Rosenheim to Innsbruck, 5 miles east of the latter. It is the seat of a district court, of a board of salt works, and of a provincial board of mines. The beautiful Gothic parish church, dating from the 13th century, contains an altar-piece by a pupil of Rubens and the copy of a Chant by Albert Dürer. The principal other public buildings are several monasteries, the gymnasium, the deaf and dumb institute and the lunatic asylum. The prosperity of the town depends chiefly upon its salt works, which are supplied by pipes from the mines at Salzbögen 9 miles distant, the annual yield of salt is from 15,000 to 16,000 tons. A considerable number of invalids visit the town on account of the salt water baths. The principal other industries are the manufacture of woollen cloth, thread, paper, and substitutes for coffee. Hall obtained town rights in 1303. It suffered considerably from earthquakes in 1663 and 1670. In 1809 the patriot Speckbacher on three separate occasions succeeded in storming the position of the Bavarians on the bridge which crosses the Inn at this point. The population in 1870 was 5101.

HALL (generally known as Swabian Hall), a town of Württemberg, circle of Jagt, is situated in a deep valley on both sides of the Kocher, and on the railway from Heilbronn to Krahsham, 36 miles N.E. of Stuttgart. It is surrounded by strong walls, and possesses seven churches, one of them dating from the 16th century and having fine medieval carving, a town house, a lyceum, a real-school of the second order, a hospital, and a house of correction. A short distance south from the town is the old castle of Kumburg, now used as a garrison for invalid soldiers, with a richly adorned Benedictine church dating from the 12th century. The town is chiefly known for its extensive salt-works, supplied by means of a pipe from Wilhelmshagen mine, 5 miles distant. Connected with the salt-works there is a salt-bath and wool-dyeing establishments. The other industries of the town are cotton-spinning and weaving, and the manufacture of leather, soap, starch, sago, brushes, pencils, machines, carriages, and metal wares. The population in 1876 was 8430.

Hall originally belonged to the counts of Westheim, and later to the Knights Templars. It was made a free imperial city in the 14th century, and was afterwards in the different leagues of the cities, knights, and counts. In 1802 it came into the possession of Württemberg.

HALL, BASIL (1788-1844), British traveller and miscellaneous writer, was born at Edinburgh, December 31, 1788. His father, Sir James Hall of Dunninglass, was author of an essay on *Gothic Architecture*, and contributed to the Royal Society of Edinburgh, of which for a time was president, several ingenious papers on geology, in support of Hutton's theory as against that of Werner. His mother was Helen, daughter of Dunbar, fourth earl of Selkirk. Basil Hall was educated at the High School of Edinburgh, and in 1803 entered the navy, where he rose to the rank of post captain in 1817. By observing the ethnological as well as the physical peculiarities of the countries he visited, he collected the materials for a very large number of scientific papers, which he contributed to various journals and encyclopedias. In 1816 he commanded the sloop "Lynx," which accompanied Lord Amherst's embassy to China, and in this vessel he performed the cruise which he describes in the most popular and perhaps the most interesting of his works—*An Account of a Voyage of Discovery to the West Coast of Corea and the Great Loo Choo Island in the Japan Sea* (London, 1818). In 1820 he held a command on the Pacific coast of America, and in 1824 published two volumes of *Extracts from a Journal written on the Coasts of Chile, Peru, and Mexico*

in the years 1820-21-23. Retiring on half pay in 1824, Hall in 1825 married a daughter of Sir John Hunter, and in her company travelled (1827-28) through the United States. In 1829 he published his *Travels in North America in the years 1827 and 1828*, a book almost as popular as his first, less from its intrinsic merit than from the violence with which it was assailed by the American press for its views of American society. *Schloss Hamfeld, or a Winter in Lower Styria* (1830), is partly a romance, partly a description of a visit paid by the author to the castle of the Countess Pargall. *Spain and the Seat of War in Spain* appeared in 1837. The *Elements of Voyages and Travels* (9 vols) were issued in three detachments between 1831 and 1840. Captain Hall was a fellow of the Royal Societies of London and Edinburgh, and a member of the Astronomical Society of London, and has left a number of scientific and miscellaneous writings besides those mentioned. His last work, a collection of sketches and tales under the name of *Patchwork* (1841), had not been long published before its author was seized with insanity, from which he was only released by his death, in Haslar Hospital, Portsmouth, September 11, 1844.

HALL, CHARLES FRANCIS (1821-1871), an Arctic explorer, was born at Rochester, New Hampshire, United States, in 1821. After following the trade of blacksmith, he became a journalist at Cincinnati, but his enthusiasm for Arctic exploration led him in 1859 to volunteer to the American Geographical Society to "go in search of the bones of Franklin." With the proceeds of a subscription he was equipped for his modest expedition, and obtained a passage in May 1860 on board a New London whaling vessel commanded by Captain Buddington, the same who had picked up the English search ship "Resolute." The whaler having become blocked up with ice, Hall took up his abode with the Eskimo, living with them for two years, adopting their habits and acquiring their language, making special friends of two natives, man and wife, who had been in England and knew something of our language. He wandered about with the Eskimo in the region to the north of Hudson's Bay, acquiring much information, especially about the people. He published an account of his experiences in 1864, under the title of *As it Really was, and Life among the Esquimaux*. Having learned little or nothing, however, about the fate of the Franklin expedition, he returned in 1864, remaining among the Eskimo till 1869. Unfortunately the full journal he kept of his five years' wanderings has never been published. The expedition which brought Hall most prominently into notice was fitted out in 1871 in the steamer "Polaris," which was sent out at the expense of the United States Government, its object being to reach the supposed open Polar Sea, and if possible attain the Pole. Hall was in command, while Buddington was sailing master. There was a modest but competent scientific staff, and among the crew were Hall's two old Eskimo friends, who had become devoted to him. On June 29, 1871, the "Polaris" left New York, and making a remarkably rapid passage up Davis Straits and Smith Sound, reached on August 30 the lat of 82° 16' N., until the last English expedition the highest northern latitude reached of which there is any authentic report. Hall and most of the officers and crew were for proceeding onwards, but they were overruled by Buddington, and went into winter quarters in a sheltered cove on the Greenland coast, named Polaris Bay, in 81° 38' N. On October 24th Hall returned from a successful sledge expedition to the north, and was suddenly seized by an illness of which he died on November 8th. As there were some suspicions of poison, an inquiry was made by the Navy Department, who found that there was no proof of foul play. Captain Buddington, on whom the command devolved, determined

in August of next year to return, but the "Polaris" was greatly hampered by the ice. The danger became so great that on October 15th boats and stores were put on the ice, on which nineteen of the crew had disembarked. Suddenly the ship broke away, and the party on the ice drifted slowly southwards for 196 days, and were picked up off the coast of Labrador, in 53° 35' N., by a whaling steamer 2000 miles from where they had parted with the "Polaris." The party in the ship reached Littleton's Island, where they passed the winter, building two boats from the boards of the vessel, in which they set sail southwards in June 1873. On the 23d of that month they were picked up by a Dundee whaler, and were brought to that town, from which they ultimately reached the United States. The scientific results of the unfortunate Hall's last expedition were of considerable importance, and have been published by the United States Government, as also has an independent account in German by Dr. Bessels, one of the scientific staff.

HALL, or HALLS, EDWARD (ob. 1647), an English lawyer who takes high rank among the earlier narrators of his country's history, was born in London about the close of the 15th century and died in 1647, the year of the death of King Henry VIII. Though his name has all the appearance of a purely English word, it is none the less of foreign origin, John Hall of Northall, in Shropshire, our author's father, tracing his lineage back to Frederick of Halle in Tyrol, whose daughter, Elizabeth, married Sir Eton Edward Hall, parson to Cambridge, and according to some accounts it would appear that at a later date he was also a student at Oxford. Entering Gray's Inn he was duly called to the bar, and we find him afterwards filling the offices of common sergeant, under-sheriff of the city of London, summer reader of Gray's Inn (1533), double reader in Lent (1540), and judge of the shroff count. The date of the first appearance of his chronicle has been matter of question, but it is generally agreed that there was no such edition as that of 1612 assigned by the older bibliographers to Berthelette. The real *editio princeps* is almost certainly that issued by Grafton in 1648, the year after Hall's death, with a continuation compiled mainly from the author's MSS., it is remarkable, says Mr. Halliell (*Collections and Notes*), as having probably more variations in the copies than any book in the language. A reprint was published in 1800 under the supervision of Sir Henry Ellis, who, however, furnished neither introduction nor comment.

Hall's work deserves a higher title than that of chronicle, partly, perhaps, by a happy accident, but partly also by the author's judicious management, it possesses no small unity of theme and construction. Beginning with the famous combat at Coventry between Henry of Hereford and Thomas Mowbray, it follows the tragic progress of the strife between York and Lancaster till it is brought to a close by the marriage of Henry VII. with Margaret of York, and then it shows England united and at rest under Henry VIII. The policy of this monarch is presented under a very favourable light, and in the religious question the author sides emphatically and intemperately with Protestantism. For all kinds of ceremonial in utterance and action he has all a lawyer's respect, and his pages are often adorned and enlivened with the pagantry and material garniture of his story. In his style he unites the redundant redundancy and painful pedantry of the medieval chronicler with that elegant and balanced balance of clauses and fanciful and forcible phraseology which not long afterwards resulted in "Euphuism." On the whole the work is not only valuable but attractive. To the historian it furnishes what is evidently the testimony of an eye-witness on several matters of interest which are neglected by other narrators, and to the student of literature it has the exceptional charm of being one of the prime sources of Shakespeare's historical plays. Complete James Gairdner, *See by Ch. studies of literature*, England, London, 1879.

HALL, JAMES (1793-1868), an American judge and the author of a number of books chiefly relating to the Western States, was born at Philadelphia, August 10, 1793. After for some time prosecuting the study of law, he in 1812 joined the army, and in the war with Great Britain distinguished himself in engagements at Lundy's Lane,

Ngara, and Fort Erie. On the conclusion of the war he accompanied an expedition against Algona, but in 1818 he resigned his commission, and continued the study of law at Putt-burg. In 1820 he removed to Shawanston, Illinois, where he commenced practice at the bar and also edited the *Illinois Gazette*. Soon after he was appointed public prosecutor of the circuit, and in 1824 legislative judge. On the abolition of the latter office four years afterwards he was appointed State treasurer, but he continued at the same time his legal practice and also edited the *Illinois Intelligencer*. Subsequently he became editor of the *Western Souvenir*, an annual publication, and of the *Illinois Monthly Magazine*, afterwards the *Western Monthly Magazine*. He died near Cincinnati, July 6, 1868.

The following are his principal works—*Letters from the West*, originally continued to the Forties, and collected and published in London in 1823, *Legends of the West*, 1823, *The Soldier's Bride and other Tales*, 1823, *The Herpes Head*, a Legend of Kentucky, 1823, *Sketches of the West*, 2 vols., 1825, *Tales of the Border*, 1826, *Notes on the Western States*, 1826, *History of the Indian Trade*, in conjunction with T. L. McKee, 3 vols., 1828-44, *The Wilderness and the War Path*, 1846, *Romances of Western History*, 1857.

HALL, JOSEPH (1574-1656), bishop of Norwich, one of the wisest as well as wisest writers of his country, was born at Birstow Park, parish of Ashby-de-la-Zouch, Leicestershire, July 1, 1574. Designed from infancy for the church, he received his early education at the school of his native place, whence in his fifteenth year he passed to Emmanuel College, Cambridge. After being chosen for two years in succession to read the historic lectures in the public schools, Hall became a fellow of his college in 1595, and in the following year received the degree of master of arts. Having taken holy orders, he in 1601 became rector of Halesd in Suffolk, near Bury St. Edmunds. Two years later he married, and in 1605 he accompanied Sir Edmund Bacon to the Spanish Netherlands. In 1612 Hall was presented to the curacy of Waltham-Holy-Croix, in Essex, and about the same time received the degree of doctor of divinity. Meanwhile his talents as a preacher, and the ability shown in his controversial writings, had brought him into notice at court. He was appointed chaplain to Francis Henry and prebendary of Wolverhampton. The latter dignity he soon resigned. In 1616 Hall accompanied the earl of Carlisle on his mission to France, but was compelled by illness to return, in 1617 he went with James I. into Scotland, and in 1618 was appointed by him one of the English deputies to the synod at Dort, but he was again forced by sickness to return before the business of the assembly was finished. The year before (1617) he had been appointed dean of Worcester. In the years that followed Hall preached frequently before the court and took an active part in the controversies of the day, especially in that between the Arminian and Calvinistic parties in the Church of England, to the latter of which he belonged. In 1624 he refused the see of Gloucester, but in 1637 became bishop of Exeter. In this position, by his toleration of lectures and his Calvinistic mode of preaching and administering his diocese, he incurred the suspicion of disaffection to episcopacy, and on three occasions appeared on his knees before the king, to answer for his puritanical practices. Hall felt bitterly these undeserved charges of law, and threatened to "cast up his rochet" rather than be subject to them. No better proof of his attachment to the Church of England is needed than his *Episcopacy by Divine Rights Asserted*, written in 1640 at the suggestion of Laud. In 1641 Hall was translated to the see of Norwich. The same year he joined several other bishops in presenting to parliament a protest against all laws passed in their enforced absence. Upon this the bishops were accused of high treason and thrown into the Tower. Hall in his *Life of James* relates the trials he underwent both at this time

and afterwards. The accusation fell to the ground, and in six months the bishops were released (June 1643), only, however, on each finding security for £5000. Hall proceeded to Norwich, which he had not yet visited, and set about his pastoral duties, but in April 1643 his revenues and personal property were sequestered by parliament, a nominal allowance of £400 a year being made for his maintenance. Mrs Hall with great difficulty obtained a fifth of her husband's property. The bishop was next ejected from his palace, and the cathedral was dismantled. Having retired to a small estate at Higham near Norwich, which he had been able to buy, he there, with his books, bought for him by a friend, spent the rest of his life, writing and preaching. "till he was flint forbidden by men, and at last disabled by God." He died 6th September 1656, in his eighty-third year.

The great bulk of Bishop Hall's writings is controversial, and therefore of comparative ephemeral interest, but some of them continue to deserve attention. His essays, published near the time of *Virginitas seu Sex Pudes*, consist of three books of *Postiles Scriptæ*, entitled into (1) Poetical, and (2) Academic, and (3) Moral, published in 1607, and three books of *Young Satyræ*, published in 1608. They appeared together in 1609. Hall claims to be the first English satirist, though Italian disputes his title, and at the same time it often disparages the satirist, which he on the other hand being very highly praised by Clarendon and Walton. In his *Postiles* (1608-11) Hall claims to be the introduction of that style of prose composition the into English, but both de la Haye and Howell anticipated him. *The Contemplations upon the Principal Passages of the History of the New Testament* (1612-16), a devout and pious work, one by which perhaps Hall is most generally known, is a happy, distinguished Roman composition of the class to which they belong by a sly and witty wit which not infrequently puts the reader in mind of Thomas Fuller. *Mundus alter et idem*, a species of allegorical romance, published in 1618, was translated into English by John Hensley, under the title of *Discourse of a New World*. Other writings of this "English Seneca," as Sir Henry Wotton called him, is a *Disputation of David Pele* (1623-31), *Christian Meditation* (1610), and *Memorabilia*, and *De rebus divinis emblemata cum Deo*, translated in 1700. An edition of his works was published in 1806 at London, in 10 vols., by the Rev. Josiah Pratt, and a later and better one, in 12 vols., at Oxford (1857-58), by the Rev. Peter Hall. A life of Bishop Hall by the Rev. John James appeared in 1826.

HALL, MARSHALL (1790-1857), the discoverer of the "dilatative nervous system," was born at Bedford, North, February 18, 1790. His father, Robert Hall, a cotton manufacturer at that place, is well known as the introducer of the modern processes of bleaching on a large scale. Having attended Blanchard's academy at Nottingham, where Kneke White was educated, Marshall Hall commenced in 1809 his studies for the medical profession at Edinburgh university. In 1811 he was elected senior president of the Royal Medical Society, the following year he took the M.D. degree, and was immediately appointed resident house physician to the Royal Infirmary, Edinburgh. This appointment he resigned after two years, when he visited Paris and its medical schools, and, on a walking tour, those also of Berlin, Göttingen, &c. In 1817, taking up his abode at Nottingham, he published his *Diagnoses*, in which he insisted that, before treatment, the exact nature of a malady should be ascertained. He rapidly acquired an extensive country practice, his improved method in puerperal cases and his dexterity of the venesection then popular attracting many patients. In 1818 he wrote the *Menses*, a work on the affections denominated bilious, nervous, &c. The next year he was elected a fellow of the Royal Society of Edinburgh, and in 1825 he became physician to the Nottingham general hospital. In 1826 he removed to London, and in the following year he published his *Commentaries* on the more important diseases of females. He pursued his studies of the effects of blood-letting, and his *Researches* (issued in 1830) were acknowledged by the medical profession to be of vast practical value. Much practical good also resulted from his warning against mistaking exhaustion for inflammation. Hall

married in 1829, and the same year he made the discovery which placed him in rank with Harvey. It is described in *A Critical and Experimental Essay on the Circulation of the Blood in the Capillary Vessels*, in which he showed that the blood-channels intermediate between arteries and veins serve the office of bringing the fluid blood into contact with the material tissues of the system. About this time he made his original investigations on quantity of respiration, detailed in *The Inverse Ratio which subsists between the Respiration and Irregularity in the Animal Kingdom*, a work which led to the treatises on hibernation. In 1831 he proposed a simple and bloodless operation for the removal of vascular nervous. His most important discovery in physiology was the "dilatative spinal system," his views being embodied in a paper on *The Reflex Function of the Medulla Oblongata and the Medulla Spinalis*, 1832, in which year he was elected fellow of the Royal Society, London. This paper was supplemented in 1837 by another on *The True Spinal Muscles, and the Extensor Motor System of Nerves*, in which he explained the real classification and distribution of the entire nervous system. The "reflex function" excited great attention in Germany and Holland, and M. Flourens described it as "a great epoch in physiology." Hall thus became the authority on the multifarious degrees of health referable to an abnormal condition of the nervous system, and he made plain the obscure class of convulsive affections. The action of strychnia as a spinal tonic or excitant, the relief of the epileptic, tracheotomy in laryngeal epilepsy, and the "ready method" in asphyxia, were among the later objects of his investigation. His "ready method"—sometimes called Marshall Hall's method—for resuscitation in drowning and other forms of suspended respiration—as perhaps the most popular of his discoveries, by its unnumbered lives have been preserved. Dr Hall lectured at various medical schools, at the college of physicians, and also at New York during his American tour. His papers in medical and scientific journals, including the *Comptes Rendus*, are remarkable for lucidity and brevity. He died at Brighton of a throat affection, aggravated by lecturing, August 11, 1857. A list of his works, most of which have been translated into foreign languages, and details of his "ready method," &c., are given in his *Memoirs* by his widow, London, 1861.

HALL, ROBERT (1764-1831), one of the greatest of English pulpit orators, was born May 2, 1764, at Ainsby near Leicester, where his father, a man whose cast of mind in some respects resembled closely that of the son, was pastor of a Baptist congregation. Robert was the youngest of a family of fourteen. In infancy his physical powers were so feeble that until two years of age he was unable to walk, and, although his expression and gestures indicated great mental vivacity, he was equally slow to acquire the faculty of articulate speech. It even appeared that he had learned to read before he was able to imitate spoken sounds, his nurse having taught him the letters of the alphabet and the formation of words from the inscriptions on the tombstones of a churchyard adjoining his father's dwelling house. When once the interest in this exercise had loosened his reluctant tongue his progress was remarkably rapid, and before he had attained his third year the fluency of his talk gave some indications of his future oratorical eminence. While still at the dame's school his passion for books absorbed the greater part of his time, and in the summer it was his custom after school hours to retire to the churchyard with a volume which he continued to peruse there till nightfall, making out the meaning of the more difficult words with the help of a pocket dictionary. From his sixth to his eleventh year he attended the school of Mr Simmons at Wigston, a village 4 miles from Ainsby

These his precocity assumed the exceptional form of an intense interest in metaphysics, partly, perhaps on account of the restricted character of his father's library, and before he was nine years of age he had read and re-read Jonathan Edwards's *Treatise on the Will* and Butler's *Analogy*. This incessant study at such an early period of life seems, however, to have had an injurious influence on his health, and may have been partly the cause of the disease from which he experienced such suffering in after life, and symptoms of whose existence began at this time to manifest themselves. Occasionally he was already troubled with intense pain in the back, and after he left Mr Simmonds's school his appearance was so sickly as to awaken fears of the presence of consumption. In order, therefore to obtain the benefit of a change of air, he stayed for some time in the house of a gentleman near Kettering, who with an impiety which Hall himself afterwards referred to as "egregious," prevailed upon the boy of eleven to give occasional addresses at prayer meetings. As his health seemed rapidly to recover, he was sent to a school at Northampton conducted by the Rev John Ryland, where he remained a year and a half, and "made great progress in Latin and Greek." On leaving school he for some time studied divinity under the direction of his father, and in October 1778 he entered the Bristol academy for the preparation of students for the Baptist ministry. Here the self-possession which had enabled him in his twelfth year to address unfalteringly various audiences of grown-up people seems to have strangely forsaken him, for when, in accordance with the arrangements of the academy, his turn came to deliver an address in the vestry of Broadmead Chapel, he broke down on two separate occasions and was unable to finish his discourse. On the 13th August 1780 he was set apart to the ministry, but he still continued his studies at the academy; and in 1781, in accordance with the provisions of an exhibition which he held, he entered King's College, Aberdeen, where he took the degree of master of arts in March 1785. At the university he was without a rival of his own standing in any of the classes, distinguishing himself alike in classics, philosophy, and mathematics. It was there formed the acquaintance of Mackintosh (afterwards Sir James), who, though a year his junior in age, was a year his senior as a student, and who became attached to him "because he could not help it." While they remained at Aberdeen the two were inseparable, reading together the best Greek authors, especially Plato, and discussing, either during their walks by the sea shore and the banks of the Don or in their rooms until early morning, the most perplexed questions in philosophy and religion. The interest of their conversation seems to have lain more in the difference than in the agreement of their opinions, but their controversy, so far from causing any even temporary estrangement, tended only to cement more closely their friendship and to deepen in each the respect for the mental and moral qualities of the other.

During the vacation between his last two sessions at Aberdeen, Hall acted as assistant pastor to Dr Evans at Broadmead Chapel, Bristol, and three months after leaving the university he was appointed classical tutor in the Bristol academy, an office which he held for more than five years. Even at this period his extraordinary eloquence had excited an interest beyond the bounds of the denomination to which he belonged, and when he preached the chapel was generally crowded to excess, the audience including many persons of intellectual tastes. It would appear, however, that, in the case of Mr Fuller, Dr Ryland, and other theological authorities, his exuberant intellectual energy and his outspoken expression of tolerance for certain aspects of Unitarianism caused trembling to be greatly mingled with their admiration, and ultimately, suspicious in regard

to his orthodoxy having in 1789 led to a misunderstanding with his colleagues and a part of the congregation, he in July 1790 accepted an invitation to make trial of a congregation at Cambridge, of which he became pastor in July of the following year. From a statement of his opinions contained in a letter to the congregation which he left, it would appear that, while a firm believer in the proper divinity of Christ, he had at this time disowned the cardinal principles of Calvinism—the federal headship of Adam, and the doctrine of absolute election and reprobation; and that he was so far a materialist as to "hold that man's thinking powers and faculties are the result of a certain organization of matter, and that after death he ceases to be conscious till the resurrection." It was during his Cambridge ministry, which extended over a period of fifteen years, that his oratory was most brilliant and most immediately powerful. At Cambridge the intellectual character of a large part of the audience supplied a stimulus which was wanting at Leicester and Bristol, but besides this his physical powers were then at their best, and were still unaffected by the constant pain which already so severely tested his powers of endurance and rendered the discharge of his duties such a marvellous triumph of will. Above all it was not till near the close of this period that his intellectual pathway was crossed by the shadow of mental derangement, and an element of weakness and uncertainty introduced into his career which for some time clouded the horizon of his hopes and perhaps placed a permanent check on his highest form of intellectual enterprise. While at Cambridge he gave to the world some of the more important of the few and small publications which, although those who were his constant hearers have affirmed that several of his imperfectly reported sermons convey a juster impression of the usual character of his oratory, are the only correct and properly authenticated records of his style of thought and composition. His first published compositions had a political origin. In 1781 appeared *Christianity consistent with the Love of Freedom*, in which he defended the political conduct of dissenters against the attacks of the Rev John Clayton, minister of Weymouth, and gave eloquent expression to his hopes of great political and social ameliorations as destined to issue nearly or remotely from the subversion of old ideas and institutions in the maelstrom of the French Revolution. In 1793 he expounded his political sentiments in a powerful and more extended pamphlet entitled *An Apology for the Freedom of the Press*, which at once obtained an extensive circulation, and doubtless to some extent aided in the formation of that public opinion which has given birth in England to the present remarkable era of gradual and unswerving political progress. On account, however, of certain asperities into which the warmth of his feelings had betrayed him, and his conviction that he had treated his subject in too superficial a manner, he refused to permit the publication of the pamphlet beyond the third edition, until the references of political opponents and the circulation of copies without his sanction induced him in 1821 to prepare a new edition, from which he omitted the attack on Bishop Hensley, and to which he prefixed an advertisement stating that his political opinions had undergone no substantial change. His other publications while at Cambridge were three sermons—*On Modern Infidelity* (1801), *Reflections on War* (1802), and *Sentiments proper to the present Crisis* (1803). From his first attack of insanity, which occurred in November 1804, he recovered so speedily that he was able to resume his duties in April 1805, but a more severe recurrence of the malady rendered it advisable for him on his second recovery to resign his pastoral office, which he did in March 1806. On leaving Cambridge he paid a visit to his relatives in Leicestershire, and then for some time resided at Enderby, preaching occasionally in some of

the neighbouring villages. Latterly he ministered to a small congregation in Harvey Lane, Leicester, from whom at the close of 1806 he accepted a call to be their stated pastor. In the autumn of 1807 he changed his residence from Enderby to Leicester, and in 1808 he married the servant of a brother minister. His proposal of marriage had been made after an almost momentary acquaintance, and, according to the traditional account, in very abrupt and peculiar terms, but, judging from his subsequent domestic life, his choice did sufficient credit to his penetration and sagacity. His writings at Leicester embraced various tracts printed for private circulation, a number of contributions to the *Electric Review*, among which may be mentioned his articles on "Foster's Essays" and on "Zeal without Innovation," several sermons, including those on *The Advantages of Knowledge to the Lower Classes* (1810), *On the Death of the Princess Charlotte* (1817), and *On the Death of Dr. Ryland* (1825), and his pamphlet on *The use of Communism*, in which he advocated intercommunion with all those who acknowledged the "essentials" of Christianity. In 1819 he published an edition in one volume of his sermons formerly printed. On the death of Dr. Ryland, Hall was invited to return to the pastorate of Broadmead Chapel, Bristol, and as the peace of the congregation at Leicester had been to some degree disturbed by a controversy regarding several cases of discipline, he declined to accept the invitation, and removed there in April 1826. About this period the malady—renal calculus—which had for many years tormented his life, an almost continual martyrdom, whose influence he had triumphed over with such marvellous fortitude, began to show signs of indirectly obtaining the mastery over his vigorous constitution, and henceforth increasing infirmities and sufferings, which rest and change of scene could do little to alleviate, surrounded with deepening external gloom the spirit whose cheerfulness and peace they seemed to leave almost totally unquaried. Gradually the inability to take proper exercise, by inducing a plethoric habit of body and impeding the circulation, led to a diseased condition of the heart, which resulted in his death, February 21, 1851.

The private manners of Hall were remarkably simple and unaffected, and it is his method of expressing his opinions was frequently impetuous, and occasionally somewhat brusque and impulsive, thus was on his rather to his constitutional energy and straightforward impulsive honesty than to an overbearing and dogmatic temper. Though exercising his sarcastic powers with great unconstraint, he reserved his severity chiefly for errors which implied some kind of moral culpability, and he was always careful to be respectful to true worth even when concealed or deformed by many superficial defects, or couched with humble rank or weak mental capacity. In reality few were more unassuming or unselfish or more continuously actuated by feelings truly charitable and benevolent. His mental absorption led to the contraction of many minor eccentricities, one of which was a frequent obliviousness to the flight of time and a consequent inability to remember his engagements. Towards the close of his Cambridge ministry he acquired the habit of smoking, and from that time his pipe was his almost constant companion and one of his principal solaces in his bodily suffering. Indeed talk and tobacco may be said to have supplied his chief means of recreation. In his conversation the calid and idiosyncrasies of his genius were better displayed than in any of his writings he has left us, and it is said to have exercised an even more captivating effect than did his finest orations. His most striking characteristics were keen, biting, and original wit, and wild and daring imaginative flights.

Both physically and mentally Hall possessed a rare combination of qualities fitting him to excel as a public speaker. He did not attain success without effort and discipline, but the

faults which hampered his capabilities were not of a formidable character. He was of powerful and athletic build, and his great breadth of chest, while it lent an impression of massiveness to his bearing, indicated abundant capacity to sustain the kind of physical exertion which oratory entails. His voice was deficient in strength and volume, but exceptionally pure and melodious, and capable of being thoroughly interpenetrated by emotion. Its inadequacy in tone was also compensated for by its great flexibility, which enabled him by the momentum of rapid utterance to obtain all the vocal force necessary to the highest oratorical efforts. According to Foster, his countenance "was formed as if on purpose for the most declared manifestation of power." The forehead was high and sloping, with well arched brows, beneath which his dark and brilliant eyes, in his more excited moments, burned and glowed with thought and passion. The lower part of his countenance indicated a vehement and headstrong temperament under the control of an iron will—doubtless powerfully reinforced by the strong moral sensibility which gave a peculiar elevation and dignity to features possessing no trait of grace or beauty. Perhaps the "stern, intense, and somewhat forbidding expression," which Foster referred to as wanting in the patient accompanying his works, had its origin partly in his constant suffering.

His gestures in speaking were few and simple, and his manner seemed to be naturally determined by his mental emotions without conscious purpose on his part. He gave the impression of thorough self-forgetfulness and absorption in his subject, and during the latter part of an oration of being wholly possessed and dominated by the thoughts and sentiments which he uttered. It is generally affirmed that in his spoken sermons his style was more easy, graceful, and various than in any of the sermons which he prepared for the press. In the latter the structure of the sentences is often formal and laboured, the rhythm artificial and monotonous, and idiomatic vigour is in some degrees sacrificed to elegance and pomp. In the higher flights of his eloquence his language was, however, unassumed for purity and happy adaptation to the thought. Indeed one of his most remarkable gifts is said to have been his extemporaneous command of a clear and felicitous vocabulary, which seemed to clothe every shade of his meaning with its appropriate expression, and whose musical cadences formed a not unimportant element in the fascination exercised by his oratory. It is true that in many cases his language had before he spoke undergone considerable mental elaboration, but he was nevertheless so little enslaved to his memory that, according to his own statement, he never entered the pulpit without omitting something which he wished to say and saying something which he wished to omit. In preaching his severe taste and deep sense of solemnity restrained every tendency to eccentricity or extravagance, and he never permitted his brilliant wit to emit even the faintest and most momentary sparkle. It may therefore be believed that on a secular platform his oratory would have been more racy and natural, and from the scope afforded for the free exercise of all his powers would have attained to a more varied perfection. In his occasional reviews his style is clear and pointed, but apart from this it is his sarcasm that chiefly conveys the impression of more than average ability. The predominant element of his eloquence was reasoning. His statements and propositions were animated with passion and illuminated by a vivid and rich if not strikingly powerful and original imagination, but in no instance did passion or imagination seem to obtain the chief sway. It was generally not till towards the close of his sermon that the spell of his eloquence asserted its highest influence over his audience. Then the various trains of thought through which he had been

guiding them seemed to meet in an intense focus where reason, imagination, and passion were blended together, and in whose light the theme he had been expounding stood revealed in such vivid truth and beauty as to captivate for the moment every heart. But though stating truth chiefly in the form of reasoning, he constantly exhibited it rather in its moral than in its theological aspects. His eloquence was indeed morally more than intellectually powerful, and its moral purpose was besides achieved not so much by the direct inculcation of moral duties, or the detection and exposure of moral deformities, as by his unconscious exhibition of his own moral elevation and of the aid and purity of his hopes and aims. Indeed in many of his sermons both the form and matter of his thought seemed to be determined rather by his own individual interest in his subject than by the consideration of the capacities and wants of his hearers. Though exhibiting a catholicity of spirit much in advance of his time, the range of his thought is completely included within the limits of traditional opinion. In treating of what he regarded as the cardinal truths of religion he is of course oratorically effective, but the dexterous and brilliant manner in which he wields the old controversial weapons does not compensate for their inherent inadequacy. He indulges too frequently in unavailing disputes against the moral character and motives of his opponents, and fails to sound the full depth of the speculative problems upon which he attempts to dogmatize. His sermons will always be esteemed by the student of English literature for their many passages of splendid and finished eloquence, but his theological writings as a whole are of course without that quaint interest attaching to representations of truth which though now old and effete originally exhibited is with the freshness and vividness of a discovery, while on the other hand they have no sufficient colouring from modern tendencies to give to them a more than superficial value in relation to those phases of religious thought which are predominant at the present time.

HALLA. See HALA.

HALLAM, HENRY, the celebrated English historian, was born at Windsor in the year 1777,—some authorities make the date one year later,—and he died at Pickhurst, Kent, on the 21st of January 1859. Notwithstanding his great fame and recent death very little seems to be known of the personal history of Hallam. He was the son of a dean of Bristol, and was educated at Eton, and afterwards went to Christ Church, Oxford, where he took his degree in 1799. He was called to the bar by the Inner Temple, and afterwards became a benchet of that society, but he does not appear to have at any time attempted to obtain practice. Early in life he devoted himself to literary work, and became connected with the brilliant band of authors and politicians who then led the Whig party. A commissionship of audits, obtained through that connexion, together with some private means, made him independent in point of worldly fortune, and enabled him to devote himself entirely to the studies of his life. He took no active part in practical politics, and was in fact unsuited by nature for the rough work of party polemics. But he was an active supporter of many popular movements—particularly of that which ended in the abolition of the slave trade, and he was throughout his entire life sincerely and profoundly attached to the political principles of the

Whigs, both in their popular and in their aristocratic aspect. Hallam's earliest literary work was undertaken in connexion with the great organ of the Whig party, the *Edinburgh Review*, where his review of Scott's *Diycles* attracted much notice. His first great work, *The View of the State of Europe during the Middle Ages*, was produced in 1818, and was followed nine years later by the *Constitutional History of England*. In 1838–39 appeared the *Introduction to the Literature of Europe in the 15th, 16th, and 17th Centuries*. These are the three works on which the fame of Hallam rests. They at once took a place in English literature which has never been seriously challenged. A volume of supplemental notes to his *Middle Ages* was published in 1848. These facts and dates represent nearly all the events of Hallam's career. The strongest personal interest in his life was the affliction which befell him in the loss of his children, one after another. His eldest son, Arthur Henry Hallam,—the “A H H” of Tennyson's *In Memoriam*, and by the testimony of his contemporaries a man of the most brilliant promise,—died in 1833 at the age of twenty-two. Seventeen years later, his second son, Henry Pittam Hallam, was cut off like his brother at the very threshold of what might have been a great career. The premature death and high talents of these young men, and the association of one of them with the most popular poem of the age, have made Hallam's family afflictions better known than any other incidents of his life. He survived wife, daughter, and sons by many years. In 1831 Hallam published *The Remains in Prose and Verse of Arthur Henry Hallam, with a Sketch of his Life*. In 1852 a selection of *Literary Essays and Characters* from the *Literature of Europe* was published. Hallam was a fellow of the Royal Society, and a trustee of the British Museum, and enjoyed many other appropriate distinctions. In 1850 he received the gold medal for history, founded by George III.

The *Middle Ages* is described by Hallam himself as a series of historical dissertations, a comprehensive survey of the chief circumstances that can interest a philosophical inquirer during the period from the 5th to the 15th century. The work consists of nine long chapters, each of which is a complete treatise in itself. The history of France, of Italy, of Spain, of Germany, and of the Greek and Sarmatic empires, sketched in rapid and general terms, is the subject of five separate chapters. Others deal with the great institutional features of medieval society—the development of the feudal system, of the ecclesiastical system, and of the free political system of England. The last chapter sketches the general state of society, the growth of commerce, manners, and literature in the Middle Ages. The book may be regarded as a general view of early modern history, preparatory to the more detailed treatment of special lines of inquiry carried out in his subsequent works, although Hallam's original intention was to continue the work on the scale on which it had been begun.

The *Constitutional History of England* takes up the subject at the point at which it had been dropped in the *View of the Middle Ages*, viz. the accession of Henry VII., and carries it down to the accession of George III. Hallam stopped here for a characteristic reason, which it is impossible not to respect and to regret. He was unwilling to excite the prejudices of modern politics which seemed to him to run back through the whole period of the reign of George III. As a matter of fact they ran back much further, as Hallam soon found. The sensitive impartiality which withheld him from touching perhaps the most interesting period in the history of the constitution did not save him from the charge of partiality. The *Quarterly*

¹ Lord Brougham, overlooking the constitutional chapter in the *Middle Ages*, censured Hallam for making an arbitrary beginning at this point, and proposed to write a more complete history himself.

Review for 1838 contains an article on the *Constitutional History*, written by Southey, full of railing and reproach. The work, he says, is the "production of a dejected politician," who "rakes in the ashes of long forgotten and a thousand times buried slanders, for the means of heaping obloquy on all who supported the established institutions of the country." No accusation made by a critic ever fell so wide of the mark. Absolute justice is the standard which Hallam set himself and maintained. His view of constitutional history was that it should contain only so much of the political and general history of the time as bears directly on specific changes in the organization of the state, including therein judicial as well as ecclesiastical institutions. But while abstaining from irrelevant historical discussions, Hallam deals with statesmen and policies with the calm and fearless impartiality of a judge. It was his cool treatment of such sanctified names as Charles, Channing, and Taurd that provoked the indignation of Southey and the *Quarterly*, who forgot that the same impartial measure was extended to statesmen on the other side. If Hallam can ever be said to have deviated from perfect fairness, it was in the tacit assumption that the 19th century theory of the constitution was the right theory in previous centuries, and that those who departed from it on one side or the other were in the wrong. He did unconsciously antedate the constitution, and it is clear from incidental allusions in his best work that he did not regard with favour the democratic changes which he thought to be impending. Hallam, like Macaulay, ultimately referred all political questions to the standard of Wing constitutionalism. This prepossession may be connected with the legal tone that runs through all his political writings. The spirit of the English lawyer is as strong in Hallam as in Bentham, who, like him, was never a preaching lawyer. It is no doubt owing to this quality that the *Constitutional History* has become one of the text books of English politics. Hallam, like Blackstone, has become an authority to whom men of all parties appeal. The origin of English institutions has since been explored with greater elaborateness by Professor Stubbs, but on leading guide to the constitution in its maturity is still Hallam.

Like the *Constitutional History*, the *Introduction to the Literature of Europe* continues one of the branches of inquiry which had been opened in the *View of the Middle Ages*. In the first chapter of the *Literature*, which is to a great extent supplementary to the last chapter of the *Middle Ages*, Hallam sketches the state of literature in Europe down to the end of the 14th century—the extinction of ancient learning which followed the fall of the Roman empire and the rise of Christianity, the preservation of the Latin language in the services of the church, and the slow revival of letters, which began to show itself soon after the 7th century—"the *natus* of the human mind"—had been passed. For the first century and a half of his special period he is mainly occupied with a review of classical learning, and he adopts the plan of taking short decennial periods and noticing the most remarkable works which they produced. The rapid growth of literature in the 16th century compels him to resort to a classification of subjects. Thus in the period 1520-1550 we have separate chapters on ancient literature, theology, speculative philosophy and jurisprudence, the literature of taste, and scientific and miscellaneous literature, and the subdivision of subjects is carried further of course in the later periods. Thus poetry, the drama, and polite literature form the subjects of separate chapters. One inconvenient result of this arrangement is that the same author is scattered over many chapters, according as his works fall within this category or that period of time. Names like Shakespeare, Grotius, Bacon, Hobbes, appear in half a dozen different

places. The individuality of great authors is thus disappointed except when it has been preserved by an occasional sacrifice of the arrangement—and this defect, if it is to be esteemed a defect, is increased by the very sparing references to personal history and character with which Hallam was obliged to content himself. His plan excluded biographical history, nor is the work, he tells us, to be regarded as one of reference. It is rigidly an account of the books which would make a complete library of the period, arranged according to the date of their publication and the nature of their subjects. The history of institutions like universities and academies, and that of great popular movements like the Reformation, as of course noticed in their immediate connexion with literary results, but Hallam had little taste for the spacious generalization which such subjects suggest. The great qualities displayed in this work have been universally acknowledged—conscientiousness, accuracy, judgment, and enormous reading. Not the least striking testimony to Hallam's powers is his mastery over so many diverse forms of intellectual activity. In science and theology, mathematics and poetry, metaphysics and law, he is a competent and always a fair if not a profound critic. The bent of his own mind is manifest in his treatment of pure literature and of political speculation,—which seems to be inspired with stronger personal interest and a higher sense of power than of other parts of his display. Not worthy of notice in a literary history is the good sense by which both his learning and his tastes have been held in control. Probably no writer ever possessed a juster view of the relative importance of men and things. The labour devoted to an investigation is with Hallam no excuse for dwelling on the results, unless that is in itself important. He turns away contemptuously from the mere unicities of literature, and is never tempted to make a display of trivial erudition. Nor do we find that his interest in special studies leads him to assign them a disproportionate place in his general view of the literature of a period.

Hallam is generally described as a "philosophical historian." The description is justified not so much by any philosophical quality in his method as by the nature of his subject and his own temper. Hallam is a philosopher to this extent that both in political and in literary history he fixed his attention on results rather than on persons. His conception of history embraced the whole movement of society. Beside that conception the issue of battle, and the fate of kings fall into comparative insignificance. "We can trace the pedigree of princes," he reflects, "fill up the catalogue of towns besieged and provinces desolated, describe even the whole paganism of coronations and festivals, but we cannot recover the genuine history of mankind." But, on the other hand, there is no trace in Hallam of anything like a philosophy of history or society. Wise and generally melancholy reflections on human nature and political society are not infrequent in his writings, and they arise naturally and incidentally out of the subject he is discussing. His object is the attainment of truth in matters of fact. Sweeping theories of the movement of society, and broad characterizations of particular periods of history, seem to have no attraction for him. The view of mankind on which such generalizations are usually based, taking little account of individual character, was highly distasteful to him. Thus he objects to the use of statistics because they favour that tendency to regard all men as mentally and morally equal which is so unhappily strong in modern times. At the same time Hallam by no means assumes the tone of the mere scholar. He is even solicitous to show that his point of view is that of the cultivated gentleman and not of the specialist of any order. Thus

* Technical subjects like painting in English law have been excluded by Hallam, and history and theology only partially treated.

he tells us the Montaigne is the first French author whom an English gentleman is ashamed not to have read. In fact, allusions to the necessary studies of a gentleman meet us constantly, reminding us of the unlikely erudition of the schoolboy in Macaulay. Hallam's prejudices, so far as he is concerned, are not of the kind which would make him apt to assume a tone of moral censure when he has to deal with certain extremes of human thought,—scepticism in philosophy, atheism in religion, and democracy in politics.

Hallam's style is singularly uniform throughout all his writings. It is sincere and straightforward, and obviously in the order of the *Literature of Europe* the least affected of the writer's meaning. In the *Literature of Europe* there are many passages of great imaginative beauty. (五.三.)

HALLE (formerly called, to distinguish it from other towns of the same name, Halle in Sachsen, but now more generally known as Halle an der Saale), a city of Prussian Saxony, government district of Merseburg, is situated on the right bank of the Saale and at the junction of six rail ways, 20 miles N.W. of Leipzig. It consists of the old town, or Halle proper, with five suburbs, and the two smaller towns of Glaucha and Neumarkt, which were added to it in 1817. Halle is under the immediate jurisdiction of the crown, and is the seat of the imperial chief office of mines for

Plan of Halle.

the provinces of Saxony, Brandenburg, and Pomerania, of a head tax-office, of a circle court, and of a provincial office. The greater part of the town is irregularly built, and presents a somewhat unattractive appearance to the eye of a stranger; but of late years it has been much improved by the construction of new promenades on the site of the old fortifications, and by the repaving of many of the streets and the addition of new buildings. Its well-known university, King Frederick I. in 1694 in behalf of the artist Thomasius, and in 1709 in behalf of the artist to Halle when he was expelled from Leipzig through the enmity of his fellow professors. It was closed by Napoleon in 1806, and again in 1813; and in 1815 it was united

with that of Wittenberg. It has faculties of theology, law, medicine, and philosophy. From the beginning it has been recognized as one of the principal schools of Protestant theology, and has numbered among its professors some of the most eminent names of Germany. Its maximum number of students occurred in 1829 when they exceeded 1300. Subsequently the number declined below 600, but at present the average attendance is between 900 and 1000. The present buildings were erected in 1834. In connexion with the university there are a botanical garden, a theological and a law library, a library of theological and medical works, a maternity hospital, an observatory, and a library of over 100,000 volumes, which also contains collections of coins and engravings. The *Francksche Stiftungen*—founded in 1691 by August Hermann Francke, a bronze statue of whom by Rauch was erected in 1829 in the inner court of the building—embrace an orphanage, a laboratory where medicines are prepared and distributed, a Bible press from which Bibles are issued at a cheap rate, and a number of schools of various grades, viz., a Latin school, a higher real-school, a citizen school, a higher female school, and a free school, all in connexion with the university. The principal other institutions are the gymnasium, the provincial trade school, the provincial lunatic asylum, the penitentiary, the town hospital and infirmary, and the deaf and dumb institute. Among the other public buildings may be mentioned the church of St Mary, containing some fine paintings, an interesting Gothic structure of the 16th century, with four towers, two of which are connected by a bridge; the church of St Maurice, dating from the 12th century, with interesting wood-carvings and sculptures; the church of St Ulrich, dating from the 14th century; the cathedral, formerly the residence of the archbishops, and now containing the remains of Duke Augustus of Saxony and his family, the red rock tower in the market-place, 276 feet in height; the old town-house; the ruins of the castle of Moritzburg, erected in 1484, formerly the residence of the archbishops of Magdeburg, but destroyed by fire during the Thirty Years' War, with the exception of the left wing, which is now used for military purposes; the lodge of the free-masons; and the theatre. In 1859 a bronze statue was erected in the market-place to Handel, who was born at Halle in 1685; and in the outskirts of the town there is a monument to Handel, and to the battle of the Marston in 1818. The salt-springs of Halle have been known from a very early period. Some rise within the town and others on an island in the Saale; and together their annual yield of salt is about 12,000 tons. The workmen employed in connexion with the manufacture are a peculiar and distinct race known by the name of *Halloren*, probably descended from an old Franconian colony. They observe several ancient customs, and enjoy certain special exemptions and privileges. The principal other industries of Halle are the manufacture of starch, beetroot-sugar, chemicals, lignite, candles, pottery-ware, sausages, oil, iron-ware, and gunpowder, and the tanning, bookbinding, and leather trades. Considerable trade, especially in corn, is now carried on by means of the railways, but the shipping trade is unimportant. The population has increased with great rapidity during the last quarter of a century, for while the numbers in 1831 were 26,593, they had risen in 1849 to 38,348 and in 1875 to 60,593. Halle was first mentioned in 808 as the fortress of Halls erected by Charlemagne. The place was, however, in existence before the Christian era, and was probably a Roman station, with salt-springs. Otto the Great presented it in 966 along with the salt-springs to the bishopric of Magdeburg, and in 981 Otto II. raised it to the rank of a town. At the beginning of the 12th century it was a free imperial city, and in 1209 it was incorporated with the bishopric as a member of the Hanseatic League (it carried on successful trade with the archbishops of Magdeburg; and in 1486 it resisted an army of 80,000 men sent by the emperor to subvert the city). With the Peace of Westphalia between the emperor and the nations it

was subdued in 1478 by Archbishop Ernest, who in order to hold it in check built the castle of Montaburg. Notwithstanding the efforts of the archbishops of Mainz and Magdeburg, the Reformation found an entrance into the city in 1522, and in 1541 a Lutheran superintendent was appointed. After the peace of Westphalia in 1648 the city came into the possession of the house of Brandenburg. In 1806 it was stormed and taken by the French, after which, at the peace of Tilsit, it was united to the new kingdom of Westphalia. After the battle between the Prussians and French, May 2, 1813, it was taken by the Prussians. The rise of Leipzig was for a long time fruitful to the prosperity of Halle, and its present rapid increase in population and trade is principally due to its position on the canal and the railway. See *Die Hauptstadt, ausführliche Beschreibung des Saalkraus*, Halle, 2 vols., 1755 (2d ed., 1771-73, 3d ed., 1849-54), Hoffmann, *Geschichte des Universitäts-Stadts Halle*, 1806, *Halle's Ver- und Gelehrten-Verzeichnis*, 1851, Karsch, *Leben des Gelehrten und Buchhändlers des Stadts Halle*, 2d ed., 1861, Vorn Hagen, *Die Stadt Halle*, 1866-67, Huitbreit, *Geschichte der Vereinigung der Universitäten von Wittenberg und Halle*, 1867, Vorn, *Zur Geschichte des Antiquariats der Stadt Halle*, 1874, A. Nankel, "Über die Legende von Altmann der Stadt Halle," in *Mittheilungen des Vereins für Erdkunde zu Halle*, Hülse, 1877.

HALLECK, FITZGERALD (1790-1867), an American poet, was born at Guilford, Connecticut, July 8, 1790. By his mother he was descended from John Eliot, the "Apostle of the Indians." At an early age he became clerk in a store at Guilford, and at eighteen he entered a banking house in New York. Having made the acquaintance of Joseph Rodman Drake in 1819, he assisted him under the signature of "Croaker junior" in contributing to the *New York Evening Post* the humorous series of "Croaker Papers." In 1821 he published his longest poem, *Fanny*, a satire on local politics and fashions in the measure of Byron's *Don Juan*. He visited Europe in 1822-23, and after his return published anonymously in 1827 a volume of poems in which were included "Alnwick Castle" and "Barny." From 1824 to 1849 he was confidential agent of John Jacob Astor, who named him one of the trustees of the Astor Library, and left him an annuity of 200 dollars, on which he retired to Guilford, where he lived with an unmarried sister. In 1864 he published in the *New York Ledger* a poem of 300 lines entitled "Young America." He died at Guilford, November 19, 1867. The poems of Halleck are written with great care and finish, and manifest the possession of a fine sense of harmony and of genial and elevated sentiments.

Editions of his poems appeared in 1836, 1843, 1849, 1858, and 1869. He is also the author of *Selections from the English Poets His Life*, by J. G. Wilson, appeared in 1869.

HALLECK, HENRY WADE (1815-1872), an American general, was born at Waterville, Oneida county, New York, January 16, 1815. After studying a short time at Union College, he in 1835 entered the West Point military academy, whence he was in 1839 promoted to the army as second lieutenant in the corps of engineers, being at the same time appointed assistant professor of engineering at the academy. In the following year he was made an assistant to the board of engineers at Washington, and from 1841 to 1844 he was employed in connection with the fortification of New York harbor. In 1845 he was sent by the Government to examine the principal military establishments of Europe, and during his absence he was promoted to the rank of first lieutenant. After his return he in the winter of 1845-46 delivered at the Lowell Institute, Boston, a course of twelve lectures on the science of war, published in 1846 under the title *Elements of Military Art and Science*, and republished with additions in 1861. On the outbreak of the Mexican war in 1846 he as military engineer accompanied the expedition to California and the Pacific coast, where he distinguished himself not only as an engineer but by his administrative skill as secretary of state, and by his presence of mind and bravery in several skirmishes with the enemy. In 1847 his services were

recognized by promotion to the rank of captain. He continued for several years to act on the staff of General Riley in California, holding at the same time the office of secretary of state of the province, and he took a leading part in framing the State constitution of California, on its being admitted into the Union. In 1852 he was appointed inspector and engineer of lighthouses, and in 1853 he was promoted captain of engineers. He, however, in 1854 resigned his commission in order to devote his chief attention to the practice of law, which he had already for some time carried on, and so great was his success in his profession that the firm of which he was senior partner soon obtained one of the largest legal businesses in the State. He was also from 1850 director of the New Almaden quicksilver mine, and in 1855 he became president of the Pacific and Atlantic Railroad from San Francisco to San José. On the outbreak of the civil war he was in August 1861 appointed major general of the United States army, and in the following November was appointed commander of the western department, where he conducted the campaign with great energy and with such uniform success against the Confederates that in 1862 they evacuated Corinth, which they had strongly fortified. In July of the same year he was appointed general in chief of the armies of the United States—a position he held till March 1864, when he was succeeded by Grant and was appointed chief of the staff. In April 1865 he held the command of the military division of the James and in August of the same year of the military division of the Pacific, which he retained till March 1869, when he was transferred to that of the south, a position he held till his death at Louisville, January 9, 1872.

Besides his work on the *Science of War*, General Halleck was the author of *Battles, its Principles, Properties, and Uses*, 1841, *The Science of Arms and Manoeuvres*, 1859, a translation of *De Foot On the Law of War*, with an introduction, 1860, *International Law*, 1861, a translation of Jomini's *Life of Napoleon*, 1861, and a *Treatise on International Law and the Laws of War*, prepared for the use of Schools and Colleges, 1866.

HALLER, ALBRECHT VON (1708-1777), one of the greatest of the anatomists and physiologists of the 18th century, was born of an old Swiss family at Basle, October 16, 1708. Prevented by long-continued ill-health from taking part in boyish sports, he had the more opportunity for the development of his precocious mind. At the age of four, it is said, he used to read and expound the Bible to his father's servants, before he was ten he had sketched a Chaldean grammar, prepared a Greek and a Hebrew vocabulary, compiled a collection of two thousand biographies of famous men and women on the model of the great works of Bayle and Moreri, and written in Latin verse a satire on his tutor, who had warned him against a too great excusiveness. When still hardly fifteen he was already the author of numerous metrical translations from Ovid, Horace, and Virgil, as well as of original lyrics, dramas, and an epic of four thousand lines on the origin of the Swiss confederation, writings which he is said on one occasion to have rescued from a fire at the risk of his life, only, however, to burn them a little later (1729) with his own hand. Haller's attention had been directed to the profession of medicine while he was residing in the house of a physician at Basle after his father's death in 1721, and, following the choice then made, he while still a sickly and excessively shy youth went in his thirteenth year to the university of Tübingen (December 1723), where he studied under Camerarius and Duverney. Dissatisfied with his progress, he in 1726 exchanged Tübingen for Leyden, where he remained, and where, as with of his fame, and where Albinus had already begun to lecture in anatomy. As that university he graduated in May 1737, undertaking successfully in his thesis to prove that the so-called salivary duct, claimed as a recent discovery by

Coschwitz, was nothing more than a blood vessel. Halle then visited London, making the acquaintance of Sir Hans Sloane, Cheselden, Pringle, Douglas, and other scientific men, next, after a short stay in Oxford, he visited Paris, where he studied under Lédian and Wanslow, and in 1738 he proceeded to Basel, where he devoted himself to the study of the higher mathematics under John Bernoulli. It was during his stay there also that his first great interest in botany was awakened, and, in the course of a tour through Savoy, Baden, and several of the Swiss cantons, he began a collection of plants which was afterwards the basis of his great work on the flora of Switzerland. In 1739 he returned to Bern and began to practice as a physician; his best energies, however, were devoted to the botanical and anatomical researches which rapidly gave him a European reputation, and procured for him from George II. in 1736 a call to the chair of medicine, anatomy, botany, and surgery, in the newly-founded university of Göttingen. The quantity of work achieved by Haller in the seventeen years during which he occupied this post was immense. Apart from the ordinary work of his classes, which entailed upon him the task of newly organizing a botanical garden, an anatomical theatre and museum, an obstetrical school, and similar institutions, he carried on without interruption those original investigations in botany and physiology, the results of which are contained in the numerous works associated with his name, he continued also to persevere in his youthful habit of poetical composition, while at the same time he conducted a monthly scientific journal to which he is said to have contributed twelve thousand articles relating to almost every branch of human knowledge. He also warmly interested himself in most of the religious questions, both ephemeral and permanent, of his day, and the election of the Reformed church in Göttingen was mainly due to his unremitting energy. Notwithstanding all this variety of absorbing interests he never felt at home in Göttingen, his untravelling heart kept ever turning towards his native Bern (where he had been elected a member of the great council in 1745), and in 1763 he resolved to resign his chair and return to Switzerland. The twenty-one years of his life which followed were largely occupied in the discharge of his duties as "ammann," to which honourable office he had been chosen by his fellow-citizens, and in the preparation of his *Bibliotheca Medica*, the botanical, surgical and anatomical parts of which he lived to complete, but he also found time to write the three philosophical romances, — *Ursory* (1771), *Alfred* (1773), and *Fabius and Cato* (1774), — in which his views as to the respective merits of despotism, of limited monarchy, and of ancient republicanism are fully set forth. About 1773 the state of his health rendered necessary his entire withdrawal from public business, for some time he supported his failing strength by means of opium, on the use of which he communicated a paper to the *Proceedings* of the Göttingen Royal Society in 1776, the excessive use of the drug is believed, however, to have hastened his death, which occurred on the 17th of December 1777. Haller, who had been three times married, left eight children, the eldest of whom, Gotthelb Emanuel, attained to some distinction as a botanist and as a writer on Swiss history.

For some account of Haller's contributions to the sciences of which he was especially an ornament, see the articles *ANATOMY* (vol. 2, p. 814) and *PHYSIOLOGY*. Schlegel is a credited but by no means an exhaustive list of his very numerous works in various branches of science and literature. (1) *Anatomical* — *Icones anatomicae* (1748-54), *Disquisitiones anatomicae selectae* (1748-52), and *Opera anatomica selectiora* (1749-68). (2) *Physiological* — *De respiratoria et urinaria anatomia* (1747), *Principia physiologica* (1747), and *Elementa physiologica corporis humani* (1767-80). (3) *Pathological and surgical* — *Opuscula pathologica* (1750), *Disquisitiones chirurgicae collectae* (1777), also several editions of Bonkræve's *Prælectiones academicae in programmate* (1750).

tuensium et medicorum (1759), and of the *Acta medica praeceptiva* of the same author (1760-71). (4) *Botanical* — *Enumeratio stirpium Helvetiarum* (1742), *Opuscula botanica* (1749), *Bibliotheca botanica* (1771). (5) *Theological* — *De iure ubi die vultusque Abrahamus dei*, *Opuscula* (1772), and *De iure ubi die vultusque Abrahamus dei* (1775-77). (6) *Poetical* — *Ædificia* (1752, 12th ed. 1777). His three romances have been already mentioned. Several volumes of lectures and "Tagelieder" or journals were published posthumously.

See J. G. Zimmermann, *Das Leben des Hrn v. v. Haller* (1758) and the notices by Lantini and Scilla in *Leben und Werke v. Langhans* (1758).

HALLEY, EDMUND (1656-1742), an eminent astronomer, was born at Haguenau, near London, October 29, 1656. His father, a wealthy apothecary, desiring to give his only son an education suitable to his promising genius, placed him at St Paul's School, where he was equally distinguished for classical as for mathematical ability. Before leaving it for Queen's College, Oxford, which he entered as commoner in 1673, he had observed the change in the variation of the compass, and, at the age of nineteen, he supplied a new and improved method of determining the elements of the planetary orbits. His detection of considerable errors in the tables then in use led him to the conclusion that a more accurate ascertainment of the places of the fixed stars was indispensable to the progress of astronomy, and, finding that Flaughaed and Hevelius had already undertaken to catalogue the visible stars in northern latitudes, he assumed to himself the task of making observations in the southern hemisphere. A recommendation from Charles II. to the East India Company procured for him an apparently suitable, though, as it proved, ill-chosen station, and in November 1676 he embarked for St Helena. On the voyage he noticed the retardation of the pendulum in approaching the equator and during his stay on this island he observed the transit of Mercury, which suggested to him the important idea of employing similar phenomena for the calculation of the solar distance. He returned to England in November 1678, having by the estimation of 690 stars won the title of the "Southern Tycho," and by the translation to the heavens of the "Royal Oak," earned a degree of master of arts, conferred at Oxford by the king's command December 8, 1678, almost simultaneously with his election as fellow of the Royal Society. Six months later, the indefatigable astronomer started for Danzig to set at rest a dispute of long standing between Hooke and Hevelius as to the respective merits of plain or telescopic sights, and towards the end of 1680 he proceeded on a Continental tour. In Paris he observed with Cassini the great comet of 1680 after its perihelion passage, and having returned to England, he married in 1682 Mary, daughter of Mr. Tooke, auditor of the exchequer, with whom he lived happily for fifty-five years. He now fixed his residence at Inlington, engaged chiefly upon lunar observations, with a view to the great desideratum of a method of finding the longitude at sea. His mind, however, was also busy with the momentous problem of gravity. Having reached so far as to perceive that the central force of the solar system must decrease inversely as the square of the distance, and applied vainly to Wren and Hooke for further elucidation, he made in August 1684 that journey to Cambridge for the purpose of consulting Newton, which resulted in the publication of the *Principia*. The labour and expense of passing this great work through the press devolved upon Halley, who also wrote the prefixed hexameters ending with the well-known line —

Mea fides est propius motu telluris attingere divos

In 1696 he was, although a zealous Tory, appointed companion of the mint at Chester, and (August 1, 1698) he received a commission as captain of the "Paradise Pink" for the purpose of making extensive observations on the conditions of terrestrial magnetism. This task he accomplished in a voyage which lasted two years, and extended

to the 52d degree of S latitude. The results were published in a *General Chart of the Variation of the Compass* in 1701, and immediately afterwards he executed by royal command a careful survey of the tides and coasts of the British Channel, an elaborate map of which he produced in 1702. On his return from a journey to Dalmatia, for the purpose of selecting and fortifying the port of Trieste, he was nominated, November 1703, Savilian professor of geometry at Oxford, and received an honorary degree of doctor of laws. Between 1713 and 1721 he acted as secretary to the Royal Society, having previously during eight years (1686-93) filled the same office, and early in 1720 he succeeded Flamsteed as astronomer royal. Although in his sixty-fourth year, he undertook to observe the moon through an entire revolution of her nodes (eighteen years), and actually carried out his purpose. He died in the full possession of his faculties, January 14, 1742, at the age of eighty-five.

Halley's most notable scientific achievements were—his detection of the "long inequality" of Jupiter and Saturn, and of the acceleration of the moon's mean motion, his discovery of the proper motions of the fixed stars, his theory of variation, including the hypothesis of four magnetic poles, revived by Hansteen in 1819, and his suggestion of the magnetic origin of the aurora borealis, his calculation of the orbit of the 1683 comet (the first ever attempted), coupled with a prediction of its return, strikingly verified in 1759 and 1835, and his indication (in 1718, *Phil. Trans.*, No. 348) of a method still used for determining the solar parallax by means of the transits of Venus.

His principal work, an *Catalogus Stellarum Austriacorum*, London, 1709, the substance of which is embodied in vol. iv of Flamsteed's *Historia Caeli*, 1725; *Synopsis Astronomiae Cometarum*, Oxford, 1705; *Astronomical Tables*, London, 1752, the eighty-one miscellaneous papers of considerable interest, scattered through the *Philosophical Transactions*. To these should be added his version from the Arabic (which language he required for the purpose) of the tactics of Apollonius of Perge, with a list of the titles of his two lost books, *De sectione conicis*, both published at Oxford in 1706, also his fine edition of the *Conics* of Apollonius, with the text by SIMPLICIUS DE THEOPHASTO at Paris, Oxford, 1716, folio. His edition of the *Sphaera* of ARISTARCHUS was published by his friend Dr. COWARD in 1758.

HALLOWEVEN or HALLOWEEN, the vigil of Hallowmas or All Saints' Day. For some account of the singular observances by which it used to be, and to some extent still is, distinguished in Scotland and elsewhere, reference may be made to such works as Brand's *Popular Antiquities*, Chambers's *Book of Days*, or better still to the well-known poem of Burns. Though sometimes neglected in modern practice, the most essential part of Hallowe'en ritual seems to consist in the lighting by each household of a bonfire at nightfall. This points to the very ancient and widely diffused practice of kindling sacred fires at certain seasons of the year. While the Germanic nations had their Osterfeuer and Johannisfeuer, the Celts had their Bealtine or Beltane (see BELTANE) and Samhainne, the former on the eve of May 1, and the latter on the eve of November 1. Probably the winter as well as the summer festival was from the beginning regarded as a season at which the faeries, were both unusually active and unusually propitious, but there is no evidence to show that the methods of divination at present usually resorted to, although of great antiquity, were originally regarded as limited in their efficacy to any one day. See Grimm's *Deutsche Mythologie*, ch. xx (Beltane), and ch. xxvii (Aberglaube).

HALLUIN, a town of France, in the department of Nord and aondissement of Lille, and 11 miles N N E of Lille, is situated near the right bank of the Lys. It contains several religious and benevolent institutions, including a hospital. The manufactures comprise linen and cotton goods, buxus, and oil. The family of Halluin or Halowin is mentioned as early as 1266. Baron Walter II. was one

of the forty hostages sent to England in 1360 in exchange for the French King John. George of Halowin or Halowin was a general in the service of Henry V, and an ambassador to England. He died in 1387, leaving several treatises in Latin. The family, to which the title of duke had been granted in 1581, became extinct about the middle of the 17th century. Population of the town (1876), 5884.

HALMSTAD, the chief town of the Swedish lan Halland or Halmstad, is situated on the east shore of the Cattagat, about 76 miles S S E of Gothenburg, and at the mouth of the river Nissa. The castle is the residence of the governor of the province. Mention of the church of Halmstad occurs as early as 1463, and the fortifications are mentioned first in 1526. The latter was demolished in 1736. The Dominican and Franciscan monasteries, formerly in the town, are now quite destroyed. The harbour, built in 1837-40, at a cost of about £6260, admits ships of 10 feet draught, by means of which some trade in deals, pitch, and tar is carried on. The salmon fishery is important. An archaeological society holds its meetings in Halmstad, and the popular magazine *Svenska Familj Journalen* is published there. There are both mineral and sea water baths in the neighbourhood. The oldest town-privileges of Halmstad date from 1307, while the first recorded extent in its military history is the battle of Nissa between Harold Hardrada and Sven Ulfsson. During the revolt of the minor Engelbekt, it twice fell into the hands of the rebels—in 1434 and 1486. The town appears to have been frequently chosen as the meeting place of the rulers and delegates of the three northern kingdoms, and under the union of Calmar it was appointed to be the place for the election of a new Scandinavian monarch whenever necessary. The lan of Halland formed part of the territory of Denmark in Sweden, and accordingly, in 1594, during his war with the Danes, Gustavus Vasa assaulted and took its chief town. In 1650, by the treaty of Copenhagen, the whole district was ceded to Sweden. In 1676 Charles XII defeated near Halmstad a Danish army, which was attempting to retake the district, and since that time Halland has formed part of Sweden. The population of the town in 1875 was 7136.

HALO (Latin, *halo*, Greek, *ἅλω*), a luminous circle of light surrounding one of the heavenly bodies. A better definition perhaps would be "a ring of coloured light formed by refraction, on the passage of light from one of the heavenly bodies through the aqueous vapour surrounding the earth." This would include comets and rainbows, and similar phenomena.

Halos may be divided into the following classes—

- | | |
|---------------|---------------------------------|
| 1. Encircling | { A Simple |
| | { B Compound, &c., halo systems |
| | { C Corona |
| | { α Rainbows |
| 2. Opposite | { β Fog bows and mist halos |
| | { γ Mountain speckles |

They are usually seen surrounding the sun or the moon, but in the tropics small halos were observed by Humboldt round the planet Venus. The formation of encircling halos of the classes A and B is generally attributed to refraction and reflexion of the rays of light by the presence of minute snow crystals in the upper strata of the air, and they occur usually when cirrus or cirro-stratus clouds exist. This theory was originated by Descartes, and was adopted by Maestlin (in 1686), and subsequently followed by Dr. Young and Sir Isaac Newton. It is, however, probable that some halos and certainly all coronas (class C) are formed by refraction of light from globules of water suspended in the atmosphere. Simple halos are either about 22½ degrees or 47 degrees in diameter. The ice or snow crystals, being hexagonal in form, sometimes produce a double refraction,

and then the large and small halos are seen at the same time, and, reflexion taking place from the surfaces of the crystals, additional halos or parts of halos are formed as in

FIG. 1.—Solar halo and parhelia seen at Brighton, June 6, 1876, by F. E. Sawyer, from 4 to 5.45 p.m. The halo was a large one, having the zenith for its centre and going entirely round the heavens. It was a white band, and passed through the sun and the mock suns. The parhelia were of prismatic colours and had flaming tails.

figs. 1 and 2. At the points of intersection of the halos, images of the sun or moon sometimes appear; when seen with the former, they are called *parhelia* or *mock-suns*, and when with the latter, *paraselenes* or *moon-moons*. They are sometimes accompanied with flaming tails, and are usually of prismatic colours, as also are the halos and coronas. The latter are seen when fleecy clouds or mist intervene between the spectator and the sun or moon, to which they are in immediate proximity, thereby being distinguished from the halos, which are formed at a distance from those luminaries. The predominating colour in coronas is red or orange.

The second principal division of halos includes those which are seen opposite to the sun and moon. The first class of these comprises rainbows (*a*), which are occasioned by refraction of the light from the sun or moon, produced by falling rain, causing a bow with the prismatic colours in concentric bands and arranged as they appear in the solar spectrum. When the rain is abundant an inner bow is formed, the colours in which are in inverted order. Rainbows when seen from mountain tops and the topmasts of ships are completely circular. Fog-bowls and mist halos (*b*) are somewhat similar.

The former are frequently white in colour, and are seen in the English Channel, and also off the banks of Newfoundland, being called by sailors "fog-salers," from their in-

FIG. 2.—Halo system observed at Aberdeen, January 25, 1876, at 2 p.m. (see Eynon's Monthly Meteorological Magazine, 1876, p. 1 and 50, and frontispiece).

FIG. 3.—A mountain spectro' as seen by F. E. Sawyer, on the Right, shortly after sunrise, August 13, 1877.

The former are frequently white in colour, and are seen in the English Channel, and also off the banks of Newfoundland, being called by sailors "fog-salers," from their in-

diating a dispersion of the fog or mist. They appear to be formed in a horizontal or very oblique plane. Mist halos are seen in the vapour of fountains or waterfalls, and resemble rainbows. Mountain spectro's (*y*) are caused by reflexion, and often appear accompanied by chromatic halos (see fig. 3). They generally occur on mountains when the sky between the observer and the sun is clear and there is a mist or cloud on the side of the mountain opposite to the sun, on which the summit of the mountain and the buildings and persons standing near are reflected. The most notable of mountain spectro's is that of the Brocken, in the Harz mountains. Howitt says of this:—

"If the fog is very dry, you see not only yourself but your neighbour; if very damp, only yourself, surrounded by a rainbow-coloured glory, which becomes more lustrous and beautiful the damper and thicker the fog is, and the nearer it approaches."

Many of the ancient descriptions of miraculous appearances in the heavens may be attributed to the phenomena before mentioned. Among the chief of these is the appearance of a cross which the emperor Constantine alleged he saw in the heavens about noon when marching against Maxentius (about 313 A.D.), and which was the cause of

FIG. 4.—A system of lunar halos and paraselenes figured in Buchan's Meteorology, p. 102.

his conversion to Christianity (Eusebius, *Vita Constanti*, i. 27). Some writers have doubted the occurrence; but it is quite possible Constantine saw part of a system of solar halos, and two of these at right angles would form a cross (see fig. 4). The *Brighton Herald* of April 10, 1852, records a similar phenomenon on April 1st of that year at Brighton:—

"Sun setting, evening very fine with slight haze westward, when a ray of brilliant light shot upwards about 20 degrees above the horizon, directly perpendicular from the sun, and soon after its appearance it was crossed by a horizontal band of light of a paler colour, but about the same breadth. It formed a perfect cross, and lasted half an hour."

Halos and rainbows are considered valuable prognostications of future weather. Fragments of rainbows seen on detached clouds are called *wind-dogs*, and are said to be a sign of wind. When the diameter of a corona contracts it shows the water particles are uniting into larger ones which may fall in rain, whereas if the corona extends, the particles are growing smaller, indicating increasing dryness. The open side of a halo is in some places considered to foretell the quarter from which bad weather may be expected.

See M. A. Bravais, "Mémoire sur les Halos et les Phénomènes optiques qui les accompagnent" (*Journal de l'Ecole Royale Polytechnique*, 31 cahier, tome 18, Paris, 1847); Buchan, *Introductory Treatise of Meteorology*, 1871; *Proc. Met. Soc.*, 1876, vol. ii., new ser., pp. 483 to 444. (F. E. S.)

HALS, FRANK, was born at Antwerp according to most authorities in 1584, and died at Haarlem in 1606. As a portrait painter second only to Rembrandt, he displayed extraordinary talent and quickness in the exercise of his art, coupled with improvidence in the use of the means which that art secured to him. At a time when the Dutch nation fought for independence and won it, Hals appears in the ranks of its military guilds. He was also a member of the chamber

of rhetoric, and (1644) chairman of the painters' corporation at Haarlem. But as a man he had failings unhappily common to persons of his profession at that age. He so ill treated his first wife that she died prematurely in 1616, and he barely saved the character of his second by marrying her in 1617. Another defect was partiality to drink, which led him into low company. Still he brought up and supported a family of ten children with success till 1654, when the forced sale of his pictures and furniture, at the suit of a baker to whom he was indebted for bread and money, brought him to absolute penury. Subsequently to this he was reduced to still greater straits, and his rent and firing were paid by the municipality, which afterwards gave him (1664) an annuity of 200 florins. We may admire the spirit which enabled him under these circumstances to produce some of his most striking productions. We regret to find his widow seeking outdoor relief from the guardians of the poor and dying obscurely in a hospital.

Hals's pictures illustrate the various strata of society into which his misfortunes led him. His banquets or meetings of officers, of sharpshooters, and guildsmen are the most interesting of his works. But they are not more characteristic than his low life pictures of itinerant players and singers. His portraits of gentlemen are true and noble, but hardly so expressive as those of fishwives and tavern heroes. His first master was Van Mander the painter and historian, of whom he possessed some pictures which went to pay the debt of the baker above alluded to. But he soon left behind him the practice of the time illustrated by Schoelae and Moro, and, emancipating himself gradually from tradition, produced pictures remarkable for truth and dexterity of hand. We prize in Rembrandt the golden glow of effects based upon artificial contrasts of low light in immeasurable gloom. Hals was fond of daylight of silvery sheen. Both men were painters of touch, but of touch on different keys. Rembrandt was the base, Hals the noble. The latter is perhaps more expressive than the former. He seizes with rare intuition a moment in the life of his sitters. What nature displays in that moment, he reproduces thoroughly in a very delicate scale of colour, and with a perfect mastery over every form of expression. He becomes so clever at last that exact tone, light and shade, and modelling are all obtained with a few marked and fluid strokes of the brush.

In every form of his art we can distinguish his earliest style from that of later years. Two Boys Playing and Singing in the gallery of Cassel, and a Banquet of Officers (1616) in the museum of Haarlem, exhibit him as a careful draughtsman capable of great finish, yet spirited withal. His flesh, less clear than it afterwards becomes, is pastose and burnished. Further on he becomes more effective, displays more freedom of hand, and a greater command of effect. At this period we note the beautiful full length of a young lady of the Berenstein family in the house of that name at Haarlem, and a splendid full length of a Patrician leaning on a sword in the Lichtenstein collection at Vienna. Both these pictures are equalled by the Banquets of Officers of 1627, and a Meeting of the Company of St George of 1633 in the Haarlem Museum. A picture of the same kind in the town-hall of Amsterdam, with the date of 1637, suggests some study of the masterpieces of Rembrandt, and a similar influence is apparent in a picture of 1641 at Haarlem, representing the "Regents" of the Company of St Elizabeth. But Rembrandt's example did not create a lasting impression on Hals. He gradually dropped more and more into grey and silvery harmonies of tones, and two of his canvases, executed in 1664, the Regents and Regentesses of the Oudemanshuis at Haarlem, are masterpieces of colour, though in substance all but monochrome.

There are portraits by Hals in many Continental galleries. Compulsively few have found their way to England. Sir Richard Wallace's, Cavaliere, Lord Chesterfield's, Toppe, Lord Rulmer's, Lake nesses of an Old Man and Woman, are the best that we can point out. A better selection may be found. At Amsterdam is the celebrated Kate Pyls, once in the Duppe collection at Dort, and the pair called Hals and his Wife, at Brussels, the painter Heythuysen, at the Louvre, Desportes, at Dresden, the painter Van der Vuer. His sitters were taken in every class of society,—admirals, generals, and burgomasters pining with melancholy, lawyers, clerks. To ignore all that we did in public galleries would involve much space. There are pictures of the most valuable kind at Brussels, five at Cassel, five at St Petersburg, three at the Louvre, two at Brussels, four at Dresden, two at Vienna. In private collections, chiefly in Paris, Haarlem, and Gennep, we find an equally important number. Amongst his most successful type portraits of fishwives and townsmen we should distinguish the Hille Bobbe of the Berlin Museum, and the Hille Bobbe with her Son in the Dresden Gallery. Itinerant players in the most ill-dressed in the Nivelle, Goldsmith collection at the Hague, and the box collection at Amsterdam. Boys and girls singing, playing, or laughing, or men drinking, are to be found in the gallery of Schwin, in the Aitchburg collection, and in the royal palace at Brussels. The latest works of Hals in each of these galleries are distinguished by comparatively black shadow.

Of the master's numerous family none has left a name except Frans Hals the younger, born about 1622, who died in 1669. His pictures represent cottages and poultry, and the Vanitas at Berlin, a table laden with gold and silver dishes, cups, glasses, and books is one of his finest works and deserving of a passing glance.

Quite in another form, and with much of the freedom of the elder Hals, Dirk Hals, his brother (born at Haarlem, died 1656), is a painter of festivals and ball rooms. But Dirk had too much of the freedom and too little of the skill in drawing which characterized his brother. He remains second on his own ground to Palamedes. A fair specimen of his art is a Lady playing a Harpsichord to a Young Girl and her Lover in the Van der Hoop collection at Amsterdam. More characteristic, but not better, is a large company of gentlemen rising from dinner, in the academy at Vienna.

HALSTEAD, a market town of England, county of Essex, is situated on the Colne Valley Railway and on a steep acclivity rising from the river Colne, 48 miles N.E. of London. Though irregularly built it has a neat appearance, and most of the streets are wide and clean. The principal buildings are the parish church, a fine Gothic edifice in the Perpendicular style, containing a monument supposed to be that of Sir Robert Bourchier, lord chancellor to Edward III., the church of the Holy Trinity, in the Early English style, erected in 1844, the Lady Mary Ramsay's grammar school, the mechanics' institute, and the coin exchange. The principal industries are the manufacture of silk, capes, and velvet. Straw plaiting, at one time the principal occupation of the women, now nearly extinct, and the population of the town in 1871 was 5783, and of the parish 6904.

HALYBURTON, THOMAS (1674-1712), a distinguished Scottish divine, was born at Dupplin, near Perth, on the 25th of December 1674. His father, one of the elected ministers, having died in 1682, he was taken by his mother in 1685 to Rotterdam, where he for some time attended with advantage the school founded by Erasmus. On his return to his native country in 1687 he completed his elementary education at Perth and Edinburgh, and in 1692 entered the university of St Andrews. In 1700 he was ordained minister of the parish of Caes, and in 1710 he was recommended by the synod of Fife for the chair of theology in St Leonard's College, the University of Aberdeen, to which accordingly he was appointed by Queen Anne. After a brief term of active professorial life he died in 1712. The works by which he continues to be known, especially in Scotland, were all of them published after his death.

The treatise entitled *Natural Religion Insufficient, and Revealed Necessary, to Man's Happiness in his present State* (1714) is an able reply to some of the arguments of Lord Herbert and of Blount, the *Great Concern of Salvation* (1721), still read, handles questions of practical and experimental religion with great earnestness and in a manner that exhibits favourably one of the best types of piety current in his time, the *Memoirs* written by himself, which have been frequently reprinted, are similarly interesting and valuable.

HAM (27), the second son of Noah (Gen v 32), and the progenitor of Cush, Mizraim, Phut, and Canaan (Gen x 6). On the assumption that these early genealogies are geographical rather than personal or even ethnological, the name Ham, which in Hebrew radically signifies "hot," would seem to indicate the torrid zone, and this inference, though not supported, so far as has been hitherto discovered, by any corresponding explanation of the names of Shem and Japheth, at least harmonizes well with the fact that on the whole Shem seems intended to denote the intermediate and Japheth the northern regions of the world as known to the compiler of the Book of Genesis. The attempt has sometimes been made to identify Ham with Kem or Chem, an old name of Egypt, signifying "black," and having reference, it is supposed, to the colour of the soil. But this identification has no adequate etymological support (see Lepsius in Herzog and Plitt's *Enzykl.*, i 166), and the allusions in several of the Psalms to Egypt as the land of Ham (Ps cv 23, cvi 22) are not inconsistent with the belief that the latter name was primarily used in a much wider and less local sense. The solitary incident regarding Ham related in Gen ix 20-27 seems intended to indicate, from the Israelite point of view, the immodest and sensual tendencies of the Canaanites and other "Hamitic" peoples.

HAM, a small town of France, in a marshy district on the left bank of the Somme, about 40 miles south-east of Amiens, on the railway between Amiens and Rheims. It had in 1876 a population of only 3122, but historically it is a place of very considerable importance. From the 9th century onwards it appears as the seat of a lordship which, after the extinction of its hereditary line, passed in succession to the houses of Courcy, Enguien, Luxembourg, Rohan, Vendôme, and Navarre, and was finally united to the French crown on the accession of Henry IV. In 1108 an abbey of canons regular of the congregation of France was founded at Ham, and it continued to exist till the great Revolution, the revenue of its abbey about that time amounting to 15,000 livres. The abbey church (Notre Dame) dates from the 12th century, but in April 1760 all the inflammable portions of the building were destroyed by a conflagration caused by lightning, and during the present century a process of restoration has been carried out under the direction of M. Coiroyer. Of special note are the bas reliefs of the nave and choir, executed in the 17th and 18th centuries, and the crypt of the 11th century, which contains the sepulchral effigies of Odo of Ham and his wife Isabella of Béthencourt. The castle, founded by Odo in the 12th century, was rebuilt in the 13th and extended in the 14th, and its present appearance is mainly due to Louis de Luxembourg, count of St. Pol, who between 1436 and 1470 not only furnished it with outworks, but gave such a thickness to the towers and curtains, and more especially to the great tower or donjon which still bears his motto *Mon Myeux*, that they would offer a long resistance even to modern artillery (Viollot-le-Duc). It forms a rectangle 395 feet long by 283 feet broad, with a round tower at each angle and two square towers protecting the curtains. The eastern and western sides are each defended by a demi-lune. The Constable's Tower, for so the great tower is

usually called in memory of St. Pol, has a height of about 100 feet, and the thickness of the walls is 36 feet, the interior is occupied by three large hexagonal chambers in as many stories. As the castle of Ham has frequently been used as a state prison both in ancient and modern times, the list of those who have tasted its hospitality is an interesting one, including Joan of Arc, Louis of Bourbon, the mariners of Charles X, Louis Napoleon, Cavaignac, and Lamortière. Louis Napoleon was there for six years, and at last effected his escape in the disguise of a workman. During 1870-71 Ham was several times captured and recaptured by the belligerents.

A view and plan of the town will be found in Caspar Meuser's *Topographia Gallia*, Frankfurt, 1655, and the former is copied in the *Gentleman's Magazine*, 1831. See also De Fausville, *Le Château de Ham*, 1842, and Ch. Gouffier, *Ham, son château*, 1864.

HAMADAN, a town of Persia, in the province of Irak-Adjem, 162 miles W S W of Teheran, in the district of the Djebel at the foot of the Elvend or Alwand Mountain, the Orontes of the ancients. It is a busy place of about 50,000 inhabitants, and has large and well stocked bazars. Its principal industry is the manufacture of copper wares. Gold is collected in the streams traversing the town, and the surrounding country is remarkable for its beauty and fertility. Every quarter is shut off from its neighbours by gates which are closed at night. The chief objects of interest are the tombs of Esther and Mordecai, and of the Arabian philosopher Avicenna. The former, constructed of black wood, are adorned with Hebrew inscriptions which may be seen figured in Keil Porter's *Travels*. According to these, the pavilion or temple over the tombs was erected in the year of the creation 4474. The ordinary inhabitants of Hamadan attach more importance to a stone image of a lion which they assert was set up by Darius a magian, to mitigate the cold from which their city suffers severely. "Hamadan," says Hamadan, echoing a common Persian complaint, "is the most hateful of towns, its children are old men for ugliness, and its old men are children for silliness." At the same time the town has produced many eminent men, among whom are Abu 'l Fadhl Ahmed Hamadan himself, Zafar ed Din the Persian poet, and Zamani. The origin of the city is carried back by Eusebius of Kells to Hamadan a grandson of Shem, but other writers are contented with a less antiquity. Its claims to be identified with the city of the classical authors have been treated under ESBATANA. The present town has almost no ancient remains, and especially there are no sculptured works. See Maynard, *Dictionnaire géographique de la Perse*.

HAMAH, the Hamath of the Bible, one of the oldest cities of Syria (Gen x 18), situated in the valley of the Orontes, 110 English miles N (by R) of Damascus. It finds a place among the northern boundaries of the Holy Land (Num xxxiv 8), and is frequently mentioned in Old Testament history (Num xii 21, 2 Sam vii 9, 1 Kings vii 65, 2 Kings xviii 34, 2 Chron vii 3, Isa x 3, Amos vi 2). The city lies in a narrow valley, the pass south of it being probably the "entering in of Hamath" (1 Kings vii 65). The Orontes flows winding through it, and is spanned by four bridges. On the south-east the houses rise 150 feet above the river, and there are four other hills, that of the *Kalak* or castle being to the north 100 feet high. Twenty-four minarets rise from the various mosques. The houses are principally of mud, and the town stands amid poplar gardens with a fertile plain to the west. The castle is ruined, the streets are narrow and dirty, but the bazars are good, and the trade with the Bedawin considerable. The numerous water-wheels (*nashah*), of enormous dimensions, raising water from the Orontes are the most remarkable features of the view. The population is stated in

official returns to consist of about 39,000 Muslims and 1000 non-Muslims. The great Hamath inscriptions first mentioned by Burckhardt have lately attracted much attention. Four stones exist covered with ideographic designs in a character as yet quite unknown. The latest researches of Mr George Smith, however, indicate that the inscriptions are probably of Hittite origin, and other relics of that once powerful nation resembling the Hamath stones have been discovered farther east.

In the year 854 a. c. (according to the 11th George Smith) Hamath was taken by Shalmaneser, king of Assyria, who defeated an army of 1,400 chariots and 10,000 footmen under Belshazzar, king of the district Agaru in 713 a. c. Tiglath-Pileser II. reduced the city to tribute, and in 710 a. c. he deposed the Hamathites, who were expelled by Aramsh, king of Galah. Another invasion was effected by Sargon in 720 a. c. After the Macedonian conquest of Syria Hamath was called Elephantine by the Greeks in honor of Antiochus IV., Epiphanes, and in the early Byzantine period it is known as by the Moslems, and in 1178 was occupied by Saladin. A brief prince of Hamath in the early part of the 14th century, is well known as an authority on Arab geography.

HAMANN, JOHANN GEORGE (1730-1788), a distinguished writer on philosophical and theological subjects, was born at Königsberg in Prussia in 1730. His parents were of humble rank and small means. The education he received was in complete harmony with systematic and the worst of definiteness in this early training doubtless tended to aggravate the peculiar instability of character which troubled Hamann's after life. In 1746 he began theological studies, but speedily deserted them and turned his attention to law. That too was taken up in a desultory fashion and quickly relinquished. Hamann seems at this time to have thought that any strenuous devotion to "bread-and-butter" studies was lowering, and accordingly gave himself entirely to reading, criticism, and philological inquiries. Such studies, however, were pursued without any definite aim or systematic arrangement, and consequently were productive of nothing. In 1752, constrained to assume some position in the world, he accepted a tutorship in a family resident in Livonia, but only retained it a few months. A similar situation in Courland he also resigned after about a year. In both cases apparently the rupture might be traced to the curious and unsatisfactory character of Hamann himself. After leaving his second post he was received into the house of a merchant at Riga named Berens, who contracted a great friendship for him and selected him as his companion for a tour through Danzig, Berlin, Hamburg, Amsterdam, and London. Hamann, however, was quite unfit for business, and, when left in London, gave himself up entirely to his fancies, and was quickly reduced to a state of extreme poverty and want. It was at this period of his life, when his inner troubles of spirit harmonized with the unhappy external conditions of his lot, that he began an earnest and prolonged study of the Bible, and from this time dates the tone of extreme mysticism which is characteristic of his writings, and which undoubtedly alienated many of his friends. He returned to Riga, and was well received by the Berens family, in whose house he resided for some time. A quarrel, the precise nature of which is not very clear though the occasion is evident, led to an entire separation from these friends. In 1769 Hamann returned to Königsberg, and lived for several years with his father, filling occasional posts in Königsberg and Mitau. In 1787 he obtained a situation as translator in the excuse office, and ten years later a post as storekeeper in a mercantile house. During this period of comparative rest Hamann was able to indulge in the long correspondence with learned friends which seems to have been his greatest pleasure. In 1784 the failure of some commercial speculations greatly reduced his means,

and about the same time he was dismissed with a small pension from his situation. The kindness of friends, however, supplied provision for his children, and enabled him to carry out the long-cherished wish of visiting some of his philosophical allies. He spent some time with Jacobi at Pempelfort and with Buchholz at Walbergen. At the latter place he was seized with illness, and died on the 21st June 1788.

Hamann's works resemble his life and character. They are entirely unsystematic, so far as method is concerned, chaotic and disjointed in style. To a reader not acquainted with the peculiar nature of the man, which led him to regard what communicated itself to him as therefore objectively true, they must be moreover entirely unattractive, and from their peculiar pathos and mysterious vagueness, probably offensive. A place in the history of philosophy can be yielded to Hamann only because he expresses in thorough, barbarous fashion an idea to which other writers have given more effective shape. The fundamental thought is with him the unsatisfactoriness of abstraction or one-sidedness. The *Logik*, *Leben*, with its rational theology, was to him the type of abstraction. Even Epiphaneism, which might appear conciliatory, was by him lightly dismissed as abstract. Quite primarily, then, Hamann tried to object to himself, to much of the Kantian philosophy. The separation of sense and understanding is for him unjustifiable, and only paralleled by the extraordinary blindness of severing nature and man. Consequently, therefore, is the one demand which Hamann expresses, and as representing his own thought he had to refer to Giordano Bruno's conception of the identity of contraries. The demand, however, remains but a demand. Nothing that Hamann has given can be regarded as in the slightest degree a realization of the ideal of system, necessary for abstract thinking, and intense personality indeed it is impossible for him to do more than utter the disjointed, oracular, obscure dicta which graced for him among his friends the name of "Logos of the North." Two results only appear throughout his writings—first, the reconstruction of belief, and, secondly, the transference of many philosophical difficulties to language. Chief as, according to Hamann, the groundwork of knowledge is, and he accepts in all scientific philosophy, of experience as being most helpful in constructing a theological view in language, which he appears to regard as somehow required, he finds a solution for the problems of reason which Kant had dismissed in the *Prolegomena*. On the applications of these thoughts to the Christian theology one need not enter.

None of Hamann's writings are of great bulk, most are mere pamphlets of some thirty or forty pages. A complete collection has been published by Bötti (*Schriften*, 8vo, 1821-28), and by Gildemeister (*Leben und Schriften*, 6 vols., 1851-78). See also Petri, *Hamanns Schriften u. Briefe*, 4 vols., 1872-8; Pöhl, *Hamann, der Augustin der Reichen, sein Leben u. litterarisches u. ästhetisches Schaffen*, 2 vols., 1874-75. A very comprehensive essay on Hamann is to be found in Hegel's *Vorlesungen über die Philosophie*, 11 (*Philos.*, 1831).

HAMASAH (more correctly HAMASCH), the name of a famous Arabian anthology compiled by Habib ibn Aus et-Tah, surnamed Abū Tamīm (occasionally ABU-TEMAR, &c.). The collection is so-called from the title of its first book, containing poems descriptive of constancy and valor in battle, patient endurance of calamity, steadfastness in seeking vengeance, manifoldness under reproach and temptation, all which qualities make up the attributes called by the Arabs *hamdash* (briefly paraphrased by Et-Tahiri as *ash-shiddah al-alam*). It consists of ten books or parts, containing all 884 poems or fragments of poems, and named respectively—(1) *Et-Hamdash*, 261 pieces, (2) *Et-Maridh*, "Dirges," 169 pieces, (3) *Et-Adab*, "Manners," 84 pieces, (4) *Et-Nash*, "The Beauty and Love of Women," 139 pieces, (5) *Et-Hud*, "Satires," 80 pieces, (6) *Et-Adab wa-l-Madith*, "Hospitality and Panegyric," 143 pieces, (7) *Et-Sufut*, "Miscellaneous Descriptions," 3 pieces, (8) *Et-Sayr wa-n-Nash*, "Journeying and Downiness," 9 pieces, (9) *Et-Mulah*, "Fleasantness," 38 pieces, and (10) *Mad-muham-mad*, "Disparage of Women," 18 pieces. Of these books the first is by far the longest, both in the number and extent of its poems, and the first two together make up more than half the bulk of the work. The poems are for the most part fragments selected from longer compositions, though a considerable number are probably entire. They are taken from the works of Arab poets of all periods

down to that of Abū Tammām himself (the latest ascertainable date being 832 A.D.), but chiefly of the poets of the Ante-Islamic time (*Jahiliyyān*), and those of the early days of El-Islām (*Mukhadimān*), and those who flourished during the reigns of the Umayyad caliphs, 660–749 A.D. (*Fidmāyyān*). Perhaps the oldest in the collection are those relating to the war of Bistis, a famous legendary strife which arose out of the murder of Kuleyb, chief of the combined clans of Bakl and Taghlib, and lasted for forty years, ending with the peace of Dhul-Majaz, about 634 A.D. Of the period of the 'Abbāsī caliphs, under whom Abū Tammām himself lived, there are probably not more than sixteen fragments.

Most of the poems belong to the class of *ex tempore* or occasional utterances, as distinguished from *qasīdahs*, or elaborately finished odes. While the latter abound with comparisons and long descriptions, in which the skill of the poet is exhibited with much art and ingenuity, the poems of the *Hamāseh* are short, direct, and for the most part free from comparisons; the transitions are easy, the metaphors simple, and the purpose of the poem clearly indicated. It is due probably to the fact that this style of composition was chiefly sought by Abū Tammām in compiling his collection that he has chosen hardly anything from the works of the most famous poets of antiquity. Not a single piece from Imrūd al-Qays occurs in the *Hamāseh*, nor are there any from 'Alqamāh, Zuhayr, or El-'Alā, En-Nābighah is represented only by two pieces (pp. 408 and 742 of Freytag's edition) of four and three verses respectively, 'Antarah by two pieces of four verses each (*Id.*, pp. 206, 208), Tarāfah by one piece of five verses (*Id.*, p. 632), Labid by one piece of three verses (*Id.*, p. 168), and 'Amr son of Kulthūm by one piece of four verses (*Id.*, p. 236). The compilation is thus essentially an anthology of minor poets, and exhibits (so far at least as the more ancient poems are concerned) the general average of poetic utterance at a time when to speak in verse was the daily habit of every warrior of the desert.

To this description, however, there is an important exception in the book entitled *En-Nasīb*, containing verses relating to women and love. In the classical age of Arab poetry it was the established rule that all *qasīdahs*, or finished odes, must begin with the mention of women and their charms (*teshib*), in order, as the old critics said, that the hearts of the listeners might be softened and inclined to regard kindly the theme which the poet proposed to unfold. The fragments included in this part of the work are therefore generally taken from the opening verses of *qasīdahs*, where this is not the case, they are chiefly compositions of the early Islamic period, when the school of exclusively stotic poetry (of which the greatest representative was 'Omān son of Abū Rabi'ah) rose.

The compiler was himself a distinguished poet in the style of his day, and wandered through many provinces of the Muslim empire earning money and fame by his skill in paucology. About 220 A.H. he betook himself to Khurāsān, then ruled by 'Abū-alīsh son of 'Alī, whom he praised and by whom he was rewarded, on his journey home to El-Iraq he passed through Hamādān, and was there detained for many months a guest of Abū'l-Wafā son of Seleme, the road onward being blocked by heavy falls of snow. During his residence at Hamādān Abū Tammām is said to have compiled or composed, from the materials which he found in Abū'l-Wafā's library, five poetical works, of which one was the *Hamāseh*. This collection remained as a precious heirloom in the family of Abū'l-Wafā until their fortunes decayed, when it fell into the hands of a man of Dnawar named Abū'l-'Awādh, who carried it to Isfahān and made it known to the learned of that city.

The worth of the *Hamāseh* as a storehouse of ancient legend, of faithful detail regarding the usages of the pagan time and early simplicity of the Arab race, can hardly be exaggerated. The high level of excellence which is found in its selections, both as to form and matter, is remarkable, and caused it to be said that Abū Tammām displayed higher qualities as a poet in his choice of extracts from the ancients than in his own compositions. What strikes us chiefly in the class of poetry of which the *Hamāseh* is a specimen, is its exceeding truth and reality, its freedom from artificiality and hearsay, the evident first-hand experience which the singers possessed of all of which they sang. For historical purposes the value of the collection is not small, but most of all these shines forth from it a complete portrait of the hardy and manful nature, the strenuous life of passion and battle, the lofty contempt of cowardice, niggardliness, and severity, which marked the valiant stock who bore El-Islām abroad in a flood of new life over the out-worn civilizations of Persia, Egypt, and Byzantium. It has the true stamp of the heroic time, of its weaknesses and crime as of its strength and beauty.

No less than twenty commentaries on it are enumerated by Hāfi Khalīfah. Of these the earliest was by Abū Rīyāh (otherwise El-Fayrūh), who died in 257 A.H.; comments from this time, in the form of the circumstances in which the poems were composed, are frequently given by El-Tubai. He was followed by the famous grammarian Abū'l-Faḥ al-Jumhūr (died 392 A.H.), and later by Shams al-Muhammadi of Khawārah (died 410 A.H.). Upon El-Maḥdī's commentary is chiefly founded that of Abū Zakiyā Yūḥayr of Tadmūr (born 421 A.H., died 602), which has been published by the late Professor G.V. Freytag of Bonn, together with a Latin translation and notes (1828–1831). This monumental work, the labour of a life, is a treasure of information regarding the classical age of Arab literature which few not perhaps its equal in extent, accuracy, and minuteness of detail, in Europe. No other complete edition of the *Hamāseh* has been printed in the West, but in 1856 one appeared at Calcutta under the names of Muḥammad Ghulam Rabbān and Kabīr al-Dīn Ahmad. Through no acknowledgment of the fact is contained in this edition, it is a simple reprint of Professor Freytag's text (without El-Tubai's commentary), and follows its original even in the misprints (corrected by Freytag at the end of the second volume, which being in Latin the Calcutta edition did not seem to have consulted). It is thus worthless as a fresh critical authority, and, owing to the absence of a commentary, of little use to the student; its only merit is that it contains in an appendix of 12 pages a collection of verses (and some entire fragments) not found in El-Tubai's edition, but stated to exist in some copies consulted by the editors, these are, however, very ones loosely edited and printed, and in many places unintelligible.

The *Hamāseh* has been rendered with the utmost skill and spirit into German by the illustrious Professor of Oriental Literature, 1846), who has not only given translations of almost all the poems proper to the work, but has added numerous fragments drawn from other sources, especially those occurring in the *Schahīd* of El-Tubai, as well as the *Shahīd* of Zuhayr, and the *Shahīd* of 'Alī, and of 'Esh Shem'ah, and the *Shahīd* of Ka'b son of Zuhayr. No such faithful interpretation of the sayings and thoughts of the ancient Arab exists to our knowledge in any modern European language; it is comparable, for fidelity, spirit, and fluency, only to Lane's translation of the *Thousand and One Nights*.

When the *Hamāseh* is spoken of, that of Abū Tammām, as the first and most famous of the name, is meant; but several collections of a similar kind, also called *Hamāseh*, exist. The best known and earliest of these is the *Hamāseh* of El-Ishtak (died 284 A.H.), of which some fragments were published by Theodor Nöldeke in his *Beiträge zur Kenntnis der Poesie der alten Araber* (Hannover, 1864). Four other works of the same name, formed on the model of Abū Tammām's compilation, as mentioned by Hāfi Khalīfah. Besides these, a work entitled *Hamāseh al-Rah* (the *Hamāseh* of wine), was composed by Abū'l-'Alī al-Ma'arī (died 449 A.H.) (C. J. L.)

HAMBATO, a form of the name **AMRATO** (q.v.)

HAMBURG, a state of the German empire, which consists of the city of Hamburg with its incorporated suburbs of St. George's and St. Pauli, the surrounding district with the town of Altona, the islands of *Helgoland*, *Sevens*, *Helgoland*, in the Elbe, the five enclaves of *Völkse*, *Hansdorf*, *in Holstein*, the communes of *Mooring* in *Lüneburg* and *Cuxhaven-Ritzbüttel* in the north-west of the duchy of Bremen at the mouth of the Elbe, the island of *Neuwark*

about five miles from the coast, and the bulwark (*wehr*) of Bergedorf, which up to 1867 was held in common by Lübeck and Hamburg. The whole territory has an area of 157.18 square miles, exclusive of 99 square miles occupied by the Elbe. Of this area 134 square miles are within the limits of the German customs, but the rest continues to be practically "abroad" in relation to the commerce of the empire. In 1871 the total population was 338,074, by 1875 it had increased to 388,618 (191,339 males and 197,279 females), by 1877 to 406,014, and by 1878 to 417,239. Administratively the state is divided into the city or metropolitan district, which had 239,107 inhabitants in 1871, the domain of the Geest land¹ with 57,216 inhabitants, the domain of the Marsch land with 52,982, the bulwark of Bergedorf with 13,113, and the bulwark of Ritzbüttel with 6557. Cuxhaven, Ritzbüttel and Bergedorf are the only towns besides the capital, and they had respectively 4103 and 3899 inhabitants in 1875. The Geestland comprises the suburban districts of Rotherbaum, Harvestehude, Eimsbüttel, Eppendorf, Hohenfelde, Uhlenhorst, Eilbeck, Barmbeck, Winterhude, Borgfelde, Haum, and Hain, which encircle the city on the north and east, and the Marschland includes various "wards,"² such as the Billwerder Anschling to the east of the city, the Steenwerder and the Little Chesbrook to the south of the Elbe, the Billwerder, the Ochsenwerder, and the so-called Vierlande or Four Districts (Corslake, Altegammes, Neugammes, and Kirchwerder) as far east as Geesthacht. While the Geestland has in many places an almost unproductive soil, the Marschland is of extraordinary fertility, and its pastures, corn-fields, and market-gardens furnish Hamburg with large quantities of country produce.

As a state of the empire Hamburg is represented in the federal council by one plenipotentiary and in the diet by three deputies. According to the present constitution, which has been in force since September 28, 1860, the legislative power is in the hands of the senate and the general body of citizens, and the executive is committed to the senate alone. Of the 18 members of the senate no less than 9 must have studied law and finance, and of the remaining 9, 7 must be representatives of commerce. The members are chosen by the senate and the burgesses after a complicated process and the burgess upon whom their choice falls is obliged to accept office for at least six years, on pain of losing his civic rights. The senate by itself has the election of the first and the second burgomaster, each of whom holds office for only a year. There are 196 burgesses, of whom 88 are chosen by ballot by the general community, 48 by and from the owners of ground within the town, and 80 by the courts and administrative bodies. They are elected for a period of six years, but as half of each class go out at the end of every three years the elections occur twice as often. Both the senate and the burgesses have the right of introducing new bills. The basis of the civil law is the *Jus Hamburgicum*, revised in 1603 and supplemented by the Roman law, but in some of the rural districts local customs prevail, and in Bergedorf the Lübeck rights are still partly in force. Hamburg has appeal to the common high court of the Free Cities in Lübeck. There is a special court for commercial disputes. Jurors are summoned in the more important trials, and since 1869 there has been public and responsible prosecution of criminal cases. The ecclesiastical arrangements

of Hamburg have undergone great modifications since the general constitution of 1860. From the Reformation to the French occupation in the beginning of this century, Hamburg was a purely Lutheran state, according to the "Recess" of 1529, re-enacted in 1603, non-Lutherans were subject to legal punishment and expulsion from the country. Exceptions were gradually made in favour of foreign residents, but it was not till 1789 that regular inhabitants were allowed to exercise the religious rites of other denominations, and it was not till after the war of freedom that they were allowed to have buildings in the style of churches. In 1860 full religious liberty was guaranteed, and the identification of church and state abolished. By the new constitution of the Lutheran Church, published at first in 1870 for the city only, but in 1876 extended to the rest of the Hamburg territory, the parishes or communes are divided into three church-districts, and the general affairs of the whole community are entrusted to a synod of 53 members and to an ecclesiastical council of 9 members which acts as an executive. A central fund for the church was formed in 1870 out of the surplus property of the convent of St John, and in some of the communes there is a church rate. According to the returns of 1871 there were 300,968 Lutherans, 5588 members of other Evangelical Churches, 7771 Roman Catholics, 194 Methodists, 2698 Christians of other sects, 13,798 Jews, and while 638 described themselves as without religion or heathens, and 7071 gave no information as to creed. Since 1871 the ratio of Lutherans to non-Lutherans must have somewhat diminished. The German Reformed Church, the French Reformed, the English Episcopal, the English "Reformed," the Roman Catholic, and the Baptist are all recognized by the state. Civil marriages have been permissible in Hamburg since 1866, and since the introduction of the imperial law in January 1876 the number of such marriages has greatly increased.

The finances of the state of Hamburg are in a generally satisfactory state, for, although the public debt has been increasing, this is due mainly to such undertakings as railways, harbour improvements, and schools. In 1876 the revenue was estimated at £1,304,161 sterling, in 1877 at £1,294,566, in 1878 at £1,350,550, and in 1879 at £1,384,630, and the corresponding expenses were stated at £1,288,503, £1,868,915, £1,422,775, and £1,607,860. The public debt, which was £26,385,042 in the end of 1874, was reduced by 1878 to £5,325,559, the former sum £1,457,775 was the remains of the great contingent loan of 1812, which originally amounted to £2,550,000.

In 1868 the old civic militia, which then consisted of 7361 men, was dissolved, all citizens and military subjects between the ages of 16 and 45 had been obliged to serve except certain state officials, and school teachers, &c. By convention with Prussia, Hamburg fulfils two battalions to the 5th Hanseatic infantry regiment.

See Statistik des Handels und Gewerbes Hamburg, 1879. J. Neumann, Neudruck des Handels-Statistik, 1874 und 1875. Gustav Ratzer, Sohn Jahrs Civil-Statistik im Handelsjahr 1874.

HAMBURG, one of the most remarkable cities of Germany and indeed of Europe, ranking as it does as the first of all the seats of commerce on the Continent, is situated on the right bank of the northern arm of the Elbe, about 93 miles from the mouth of that river, just where it is joined by the Alster and the Bille. The latitude of the observatory in the western part of the city is 53° 33' 58" N and the longitude 9° 58' 23' 8" E, the latitude of the tower of St Michael's 53° 33' 55' 7" N and the longitude 9° 58' 41' 7" E. Were it not for political and municipal boundaries Hamburg might be considered as forming one town with Altona and Ottensen, the three presenting to the river a continuous frontage of nearly 4 miles, and long lines of suburbs radiate inland in various directions. The city proper lies on both sides of the Alster, which having been dammed up a short distance from its mouth now forms a considerable lake, of which the southern portion within the line of the fortifications bears the name of the Inner Alster (*Innerer Alster*), and the other and larger portion (2300

¹ Geest is a Platt Deutsch word signifying "dry," and the Geest land is consequently the higher and drier district, in contrast to the marsh land. The surface of the Geestland is composed of sand and gravel, and part of it is occupied by heath.

² Werder, Waider, or Wörth is either equivalent to the old English "holm," a river island, or signifies a stretch of flat land between a river and a piece of standing water, or a portion of a swamp drained and devoted to tillage.

metres long and 1200 metres wide at the widest) that of the Outer Alster (*Aussen Alster*). The fortifications as such were removed in 1815, but they have left their trace in a fine girdle of green round the city, though too many inroads on its completeness have been made by railways and roadways. The oldest portion of the city is that which lies to the east of the Alster; but, though it still retains the name of Altstadt, nearly all trace of its antiquity has disappeared, as it was rebuilt after the great fire of 1842. To the west lies the new town, incorporated in 1678; beyond this and contiguous to Altona is the quondam suburb of St Pauli, incorporated in 1876, and towards the north-east is the quondam suburb of St George, which arose in the 13th century, but was not incorporated till 1868. The old town lies low, and it is traversed by a great number of narrow canals or "fleets" (for the same word which has left its trace

in London nomenclature is used in the Low-German idiom which add considerably to the picturesque quality of the scene, and serve as convenient channels for the transport of goods. They generally form what may be called back streets, and they are bordered by warehouses, cellars and the lower class of dwelling-houses. As they are subject to the ebb and flow of the Elbe, at certain times they quite dry, and afford a field of operations for the *fleetenkie*, who wanders along the oozy channel to pick up any article of value, and at other times they are filled 15 to 20 feet at their ordinary level.¹ As soon as the telegram at Cuxha announces high tide three shots are fired from the Stint at the harbour to warn the inhabitants of the "fleets"; if the progress of the tide up the river gives indication of danger, other three shots add emphasis to the warning. Then the dwellers on the lower levels make a rapid escape

with their property. At the time of the equinoxes the inundation may be repeated for several days in succession; but when all is over the people (the *Lüd von de Waterkant*) return like rats to their oozy and dripping abodes. In fine contrast to the dull and dismal fleets is the bright and handsome appearance of the Inner Alster, which is enclosed on three sides by handsome rows of buildings, the *Alsterdamm* in the south-east, the *Old Jungfernstieg* in the south-west, and the *New Jungfernstieg* on the north-west, while it is separated from the Outer Alster by part of the rampart gardens traversed by the railway which unites Hamburg with Altona. These streets and especially the *Old Jungfernstieg* are fashionable promenades. The largest of the public squares of Hamburg is the *Hopfenmarkt*, which contains the church of St Nicholas, and is the principal market for fish, meat, vegetables, and fruit;

others of importance are the *Gänsemarkt* or *Goose Market*, the *Zeughausmarkt*, and the *Great New Market*, churchyards, of which several are pleasantly laid out, all to be removed to Ohlsdorf, about 4 miles from the town.

Of the churches actually existing in Hamburg (the cathedral had to be taken down in 1805), St Peter's Nicholas, St Catharine's, St James's, and St Michael's, those that give name to the five old city parishes. The church of St Nicholas is remarkable more especially for its tower, which until the spire of the Cologne cathedral reached its projected elevation of 511 feet, will probably continue to be the second highest building in the world, rising e-

¹ In 1848 *peeples* or water-gauges were established at Hamburg Cuxhaven. In 1872 their zeros were lowered respectively 9.80 and 4.31 ft., so that they both stand 9.6 ft. above the zero of Har and 10.7 above that of Kiel.

was afterwards extended to Schwane and Barm, and a branch line was constructed to Laback. The Hamburg Laback direct line was opened in 1865, and in the following year a line was constructed between Altona and Hamburg. Direct communication with Paris by way of Harburg, Bremen, and Varel was obtained only in 1872. Though as early as 1862 a scheme was set on foot for such a line, the projectors could not come to terms with the Hanoverian Government, which objected to the duty of Oldenburg obtaining a share in the advantages of the scheme, and wished to keep to itself the whole authority over the bridges on the Elbe which, leaving the cost of their construction wholly to Hamburg. In 1866 the Hanoverian Government was swept away by Prussia, and in 1868 the new rulers formed a treaty. Hence construction of the line. The two main branches of the Elbe, the north and the south, are crossed by two great bridges on the system named after Lohse, which had never before been employed in Germany. As the soil is untriable, the pillars had to be founded on a bed of concrete 17 or 18 ft thick resting on piles. The Hamburg or north bridge has three spans each 334 feet wide, and the Hamburg bridge has four spans. The total weight of iron employed was 84,651 cwt. (30,152 for the one and 48,499 for the other). For its natural location the city has a system of tramway lines which run out to Wandsbeck and other neighbouring villages, and a still more extensive omnibus system. Small steamers plying in the Outer Alster gave easy access to the places along its shores.

In 1811 the population of Hamburg (*Stadt and Fockstedt*) was 106,093, in 1851 it was 145,415, and by 1861 it had reached 166,244. Its subsequent increase is shown in the following table—

	1800	1807	1817	1826	1836	1846	Per cent
Inner town and inner belt	1,494	100,774	100,774	100,774	100,774	100,774	
St. George's	40,771	52,473	57,097	61,911	75,540	84,651	44.9
St. Pauli	29,185	31,776	41,821	45,900	50,671	66,8	
	217,020	224,070	239,707	248,677	267,873	291,5	

If we include in our survey the suburban parishes of Fockstedt, Altona, Ottensen, and Wandsbeck, we find that there were clustered together 455,685 persons. In 1871 the population of males to females in the whole Hamburg territory was 100 to 105, and in 1875 it was 100 to 103. The number of females in proportion to the males is much greater among the two than among the immigrant part of the population, and the proportion of natives to immigrants is a steadily decreasing one—76 per cent in 1867, 68 per cent in 1871, and 56 in 1875. Most of the strangers are from the neighbouring parts of Germany, 43,623 in 1871 were from Holstein, 80,946 from Hanover, and 15,886 from Mecklenburg-Schwerin. The following table shows the occupations of the people in 1871.

	Males	Females	Total
Agriculture	7,483	7,092	14,575
Industry	60,878	67,192	128,070
Trade and commerce	49,701	21,49	100,200
Of the personal service	10,860	18,796	29,656
Other callings	10,200	11,200	21,400
Without calling	6,708	17,218	24,926
Not returned	810	1,020	1,830

The number of marriages, partly in consequence of the changes in the marriage laws, is rapidly increasing (829 to every thousand marriages in 1861, and 926 to every thousand in 1875), and a similar increase is observable in the births.

The death rate varied from 26 to 30 per thousand per annum from 1872 to 1876. Consumption and acute diseases of the respiratory organs are the most prevalent causes of death. Between 1831 and 1878 there were 14 visitations of cholera, by far the most violent being those of 1832 and 1848, which caused respectively 1662 and 1765 of the population.

History.—Hamburg, as the oldest documents have it, Hamma-burg, appears to have taken its rise as a frontier block house on castle on the Slavonic borders of Germany, which in the 9th century lay thus far to the west. The block house, which may have been preceded by some insignificant hamlet, was founded by Charles the Great in 808, and he was just on the point of making the newly erected church the seat of a bishopric when he died in 814. His scheme was not carried out, but by his son Louis the Pious in 831, and three years later a charter was issued at Aix la Chapelle and confirmed by Gregory IV. raising the bishopric to the rank of an archbishopric, which was to include not only the surrounding district of Germany, but also the Slavonic lands, and the whole Scandinavian territory. Ansgarius, the first occupant of the see, was a monk and a school, but in 887 (or 889 according to other accounts) his labours were a widely interrupted by the Norman pirates, who laid the last elements of his life. Other dioceses followed, a large portion of the original territory of the archbishopric fell away from its allegiance, and in 847 it was decided at a synod at

Mann under the presidency of Hrabanus Maurus that Hamburg should be attached to the bishopric of Bremen, and the seat of the archbishopric be in the latter city. The title of archbishopric of Hamburg remained in use till 1228, though that of archbishopric of Bremen was not used as the 12th century. All through the 10th century Hamburg continued to suffer from the incursions of the Danes and the Slavonians, and the latter indeed were in possession from 982 to 987. In spite of all the setbacks advanced. Archbishop Albert built a cathedral in 1097, Archbishop Adolph not long after a castle, and the harbor wrought by Jail Skio of Denmark in 1072 was promptly repaired. In 1110 the counts of Schaunburg got possession of Holstein and Hamburg, and from thence in many ways furthered the progress of the city. In 1128 the emperor Frederick I. obtained for the town from the emperor Frederick I. in 1139 the right of a seigniorial court and jurisdiction, freedom from toll to the mouth of the Elbe, and right of fishing in the river. The charters from Flanders now began to visit the place, and its importance as a commercial centre was increased by the destruction of the flourishing town of Brabanc in 1189 by Henry the Lion. After passing under the lordship of Waldemar of Schleswig (1201) and Albrecht of Olanmunde (1216), it was recovered by the Schaunburg counts, who erected a strong castle over against it (1231). The alliance with Laback, concluded in 1241, and consummated by the treaty of 1255, was really the basis of the great Hanseatic League, of which Hamburg continued to be one of the principal members. With its foreign relations were thus improved, its internal organization was also rendered more stable by the new constitution of 1270, and the recognition of the municipal autonomy of the counts of Schaunburg in 1292. The domain of the city was increased in the 14th century by the purchase of Eppendorf, Ritzefeldt, &c., in the 15th the Russian princes who had invaded the neighbourhood in the month of the Elbe were completely defeated. The claims of the emperor Charles V. in 1529 of the city were rejected, and the imperial edict of 1510 under Maximilian I. declared that it was a city of the empire. Not long after two great changes took place. By the so-called "Long Revolt" of 1529 the Reformation was introduced, and the city was divided. Laback set the city free to follow her own path of progress. Though the troubles of the Thirty Years' War Hamburg escaped almost unscathed, but it suffered from the effects of its own lagged position, which drove many of the German nobles to seek refuge to become the founders of the neighbouring Altona. In 1603 it received a code of exchange, and in 1615 the first imperial post. Its population was not long afterwards increased and its commerce quickened by a number of the Jewish refugees who fled from Spain and Portugal. The course of the 17th century was marked by discord and strife between the senate and the lower classes, which ultimately brought about the mixture of the empire and the publication of the "Great Decree" of 1717. Though the counts of the empire had decided in 1618 against the claims of the Hamburg crown, and had confirmed this decision in 1680 and 1683, Christian V. of Denmark in its endless attempts to take Hamburg by direct force, but he accepted a ransom of 250,000 rixdollars, and at length in 1700 by the treaty of Gottorp the Danish crown renounced all its claims, and in 1770 the delegates of the city took their place in the "Alliance of the Empire" of the imperial diet. From 1700 to 1717 Hamburg was a German independent, the commerce of Hamburg drew new life but suffered terribly during the years of the French revolution. The town was not only obliged in 1802 to pay 2,125,000 francs to the Hanseatic confederation, but in 1806 it was to admit a French garrison within its walls, and to feel the effects of the British blockade of the Elbe. In 1800 indeed it had the honour of being incorporated in the French empire as the chief town of the department of the "Mouth of the Elbe," but the setback of the French emperor's defeat at Jena on 12th March 1813, and the subsequent entrance of the Russian Tzar into the city on the 18th, was welcomed by the Hamburgers. But their joy was premature, for by the 30th of May the army was again in possession of Denmark. The new general, not only demanded a contribution of 48,000,000 francs, but confiscated the 7,500,000 marks banco (of about 1/2 80) at that time in the bank, forced the inhabitants to work at the new fortifications, and drove 20,000 or 30,000 of them out of the city, and the cold of winter. In spite of the attacks of the Russians under Bennigsen, Denmark maintained his position till the close of the year. The whole loss of the city from 1806 to 1814 is estimated at £10,500,000 sterling. In 1815 Hamburg became an independent state of the German federation, and joined with Laback, Bremen, and Frankfurt the cause of the free cities. Its trade rapidly recovered, and in 1848 the great fire destroyed 4219 buildings and rendered nearly 20,000 persons homeless. Its debt was reduced to a sum of 48 million marks banco. The old oligarchical constitution had been restored after the recovery of independence, and the internal history of the town from 1840 till 1860 was mainly a protracted contest between the old and the new. The year 1858 was remarkable for a great commercial crisis, and for the meeting in the town of the commission of the navigation of the Elbe, and of the delegates appointed by the principal German states to consider matters law. By the new

possession of the whole of Sicily with the exception of the two strongholds of Drepanum and Lilybæum, and these they were blockading. They had then almost to drive Hamilcar from his position, but in vain. At last he quitted his stronghold, and in 241 B.C. landed at Mount Eryx, on the western coast, now Mount S. Giuliano, 3 miles from the shore and about 6 from Drepanum. A famous temple of Venus crowned the summit, and half-way up the slope was the city, which itself had the name of Eryx. Thus Hamilcar seized and occupied. His object was to compel the Romans to give up the blockade of Drepanum and Lilybæum. They could not drive him out of the town, and for two more years he held his position, keeping open his communications by sea with the Carthaginian garrison of Drepanum. Hamilcar's chief difficulty was with his mercenaries, who were little better than savages and with out an idea of loyalty or good faith. Yet he continued to hold them well in hand. It was a harassing and monotonous warfare, so much so that Polybius, one of our chief authority, compares it to a boxing match between two skilful pugilists, the blows in which are delivered in such rapid succession that a spectator could hardly see, much less, describe them. The Romans, feeling it necessary to make a supreme effort, in 213 B.C. equipped a fleet, under the command of the consul Lucius Catulus, and despatched it to the western shores of Sicily. The battle off the Ægates followed, and the Roman victory decided the First Punic War in 212 B.C. Peace had now to be concluded. The cession of Sicily to the Romans was a matter of course. But though Hamilcar had to surrender the island, he refused to comply with the Roman demand that his army should pass under the yoke. The demand was not persisted in, and Hamilcar and his men were allowed to embark from Lilybæum for Africa.

No sooner had peace been concluded than those broke out the so-called African or Libyan War. It was a most formidable mutiny or insurrection. Hamilcar's mercenaries on their return looked for the pay which he had promised them, but had not been able to furnish while he was occupied in within his lines on Mount Eryx. The stupidity of the home Government soon caused trouble. The peace party at Carthage, headed by Hanno, who hated Hamilcar, was foolish enough to raise a dispute about the pay of the troops. The result was a furious mutiny, which Hanno, who was sent to quiet them, could not appease. The men to the number of 20,000 began to march on Carthage itself, and encamped near Tunis. The mutineers were led by Spendius, a fugitive slave from Campania, and by Mutho, an African who had served with distinction under Hamilcar in Sicily. These two men incited all the neighbouring tribes to rise against the dominion of Carthage. Carthage itself was soon cut off from all communication with the interior. Hanno was called to take the command, but it was only to meet with defeat and disaster. The rebels surprised and captured his camp. The Government was now thoroughly frightened, and begged Hamilcar to save them from the consequences of their own folly. With a force of only 10,000 men he had to face what must now have grown into a very formidable host. It would seem that his personal influence led many of the rebels to return to his standard, and he was also skilful enough to secure the friendship and aid of the Numidian sheiks. One especially, Naravas, helped him very materially, and with his assistance he was able to achieve a decisive victory over the mutineers. At last he so effectually hemmed in Spendius within his camp near Tunis that the rebel leader was obliged to throw himself on his mercy. With one of his brother leaders he sought an interview with Hamilcar. Hamilcar's demand was the surrender of ten of the rebels, whom he was to name himself. This being agreed, he

called Spendius and his nine companions, a proceeding which the mutineers furiously resented. But they were soon surrounded and cut off to a man, to the number, it is said, of 40,000. The war, which had lasted three years and four months, was now over in the year 218 B.C.

One would have supposed that Hamilcar would be at once recognized as the right man to direct the future policy of the state. But it was not so. Hanno's party, the peace party, was as short-sighted as ever, and actually dared to say that Hamilcar had been the cause of the late war by having made promises which he was not able to fulfil. But by this folly they injured and weakened themselves. The patriotic party, the "Barine faction," as it was called by its opponents, prevailed so far as to cause then leader to a position answering as nearly as possible to a dictatorship among the Romans. Hamilcar was made commander-in-chief of the Carthaginian army in Africa, and invested with a power which could be taken from him only by the popular assembly. He was still a young man, under thirty years of age. For a short time he employed himself in overhauling the Numidian tribes bordering on Carthaginian territory, but his main object was to form the nucleus of an efficient army out of his Libyan mercenaries. Meanwhile he was maturing a great plan which soon afterwards on his own responsibility he carried into execution. Spain was a country the coast of which he had well known to the Carthaginians. Spaniards had been sent among Hamilcar's troops. To Spain he decided to go, there, he felt sure, he could find material for an army and abundant means of providing pay. He had now three sons, the "lion's blood," as he called them, Hannibal, Hasdrubal, Mago. Wishing with all his heart that they should be like minded with himself, he made the eldest, Hannibal, then a little boy of nine, swear on the altar of the supreme Carthaginian deity eternal hatred and enmity to Rome. This was just before he left Carthage, probably in the spring of 236 B.C. Suddenly these came tidings to the home Government that their commander in chief was, without their orders, carrying on war in Spain. He had, however, done his work so thoroughly in Africa that the troublesome Numidian tribes were now submissive to Carthage, and for the most part paid tribute. He never returned. The last eight years of his life he devoted to the great work of reducing Spain to a Carthaginian province. He penetrated into the interior of the country, subduing some of the tribes by force of arms and drawing others into friendly relations by negotiation. It was not to mere conquest that he aspired, he did his best to win the good-will of the Spaniards and to attach them to Carthage. Spain was to be a compensation to Carthage for the loss of Sicily and Sardinia. But, above all, its possession was to be subordinate to Hamilcar's great design of some day renewing the war with Rome. For this he would have felt himself prepared when, in addition to his Numidian cavalry, he had organized a force of Spanish infantry. Had his life been prolonged, he would doubtless, as Livy says (xvi. 2), have invaded Italy at the head of a Carthaginian army. What he accomplished in Spain so much impressed the elder Cato, who less than half a century afterwards, saw the traces of his work, that he declared that there was no king like Hamilcar Barca. In the prime of his years he fell in battle in 228 B.C., fighting, it would seem, somewhere between the Tagus and the Douro. Spain was now left in the hands of his son-in-law Hasdrubal. (W. J. N.)

HAMILTON, a municipal and parliamentary borough and market-town of Scotland, county of Lanark, is situated about a mile from the junction of the Avon with the Clyde and 10 miles S.E. of Glasgow. It occupies a rising ground commanding fine views of a rich and highly picturesque country, and consists of several streets of well-built houses

somehow irregularly disposed, and surrounded by a number of villas belonging chiefly to persons engaged in business in Glasgow. The principal buildings are the town hall, the county buildings in the Grecian style of architecture, the academy, the St John's grammar school, and the infantry barracks. Among the subjects of antiquarian interest are Queen's Neck, the spot where Queen Mary rested on her journey to Langside, the old steeple and pillory built in the reign of Charles I., the Moat Hill, the old House clove, and the carved gateway in the palace park. In the churchyard there is a monument, with four heads in basso rilievo, to four covenanters who suffered at Edinburgh, December 7, 1600, their heads being interred below. Among the industries of the town are weaving and the tanning of mauls, and there are also large market gardens, the district being famed especially for its apples, but the prosperity of the town depends chiefly upon the coal and iron stone which are extensively worked in the neighbourhood. Hamilton originated in the 15th century under the protecting influence of the lords of Hamilton. It unites with Andrie, Falkirk, Lanark, and Linthgow to form the Falkirk district of boroughs, which returns one member to parliament. The population in 1871 was 11,498.

Immediately east of the town is Hamilton place, the seat of the duke of Hamilton and Brandon, marquis of Scotland. The present palace was commenced in 1822. Its front is a specimen of the enriched Corinthian architecture, with a projecting pilaster portico after the style of the temple of Jupiter Stator at Rome, 284 feet in length and 60 feet in height. The interior is richly decorated and contains one of the most valuable collections of paintings in Scotland. Within the grounds, which comprise nearly 1500 acres, is the magnificent gravel by the tenth duke, a structure resembling in general design that of the emperor Hadrian at Rome, being a circular building springing from a quadrilateral and enclosing a deserted octagonal chapel. About 3 miles south east of Hamilton, on the summit of a picturesque rock 200 feet in height, the forest of the which is washed by the Avon, stand the ruins of Cadzow Castle, the original seat of the Hamilton family, confided on the chief of that family immediately after the battle of Bannockburn, having been previously a royal residence for at least two centuries. The castle has been made the subject of a spirited ballad by Sir Walter Scott. Now it is the noble chieftain with its ancient oaks, the remains of the Chalcidonian Forest, where as still preserved some of the old Scottish breed of wild cattle. Opposite Cadzow Castle on the other side of the Avon is Chastellum, consisting of stables and offices, and imitating in outline the palace of that name in France. A magnificent double avenue stretches between it and Hamilton palace.

HAMILTON, a city of Canada, the chief town in the county of Wentworth, province of Ontario, is advantageously situated on the south side of Burlington Bay, a large and beautiful basin of water connected with Lake Ontario by a short canal, which forms one of the safest and most commodious harbours on the lake. It is also connected with the town of Dundas by the Desjardins Canal, about 4 miles in length. Hamilton holds an important position at the head of the navigation on Lake Ontario, and in the centre of one of the finest agricultural districts of the Dominion. It is the headquarters of the Great Western Railroad, and is connected by other lines of railway with Lake Erie, Lake Huron, and the Georgian Bay. The site on which it is built rises gradually from the bay to the foot of a lofty bluff called "The Mountain," the summit of which commands an extensive and beautiful view. The streets are well laid out, and planted with shade trees, and the houses and public buildings are substantially constructed of stone and brick. The court house and county buildings, recently completed, are the finest in Canada. Among the other public buildings are the provincial lunatic asylum, the Anglican and Roman Catholic cathedrals, and handsome places of worship of other denominations, the college institute, the Wesleyan female college, the mechanics' institute, the banks, the city hospital, and other charitable institutions. The city water-works, by means of which a constant supply of pure water is brought from Lake Ontario, have been

completed on a scale amply providing for the future growth of the city, at a cost of about \$1,000,000. The industries include iron rolling mills, iron foundries, the manufacture of agricultural implements, sewing machines, musical instruments, carriages, glass, pottery, &c., tobacco manufacture, and brushmaking. The total value of imports at the port of Hamilton for the fiscal year 1878-9 was \$3,992,124, and the duty collected amounted to \$689,153. The total tonnage entered at the port was 160,666 tons, but this is exclusive of a much larger amount of goods brought by railway, including foreign importations, on which the duty has already been paid at Quebec or Montreal, and of which therefore no entry is made. Daily lines of steamers run in the summer months between Hamilton, Toronto, Kingston, and Montreal, and an extensive trade is carried on with the maritime provinces. Hamilton was founded in 1813, and incorporated in 1838. The population in 1856 was 2846, in 1861, 10,348, in 1861, 15,096, in 1871, 26,716, and in 1879 it is estimated at 36,000. It is the seat of the Anglican bishop of Niagara, and of a Roman Catholic bishop. It returns one member to the provincial parliament of Ontario, and two members to the Dominion parliament, or House of Commons.

HAMILTON, a township and post village of Madison county, New York, U.S., is situated on the Chenango canal, and on the Utica branch of the New York and Oswego Mohawk Railway, 30 miles S.W. of Utica. The village is the seat of Madison university, chartered in 1846, in connection with which there is a theological seminary of the Baptist denomination opened in 1820, and a preparatory academy opened in 1832 under the name of Colgate Academy, and chartered in 1863 as the grammar school of the university. The university has 10 professors, has both a scientific and a classical course, and is attended by upwards of 100 students. The other educational institutions are a female seminary and a union graded school. The village possesses a foundry, a tannery, and manufactories of sashes and blinds, doors, waggons, cigars, and cheese. The population of the village in 1870 was 1629, and of the township 3687.

HAMILTON, a city of the United States, capital of Butler county, Ohio, is situated on both sides of the Great Miami river, on the Miami and Erie canal, and at the junction of several railways, 23 miles N. of Cincinnati. The water power for manufacturing purposes is obtained by an hydraulic canal which secures a fall of 30 feet, and the situation of the city in the heart of the Miami valley, a rich agricultural district, is very favourable to the development of commercial enterprise. It possesses two public parks, twelve churches, two national banks, a complete graded system of public schools, an orphan's home, and a free library. Its industries are of a varied kind, and are represented by paper and woollen factories, flour-mills, foundries, breweries, distilleries, bleaching works, machine shops, and manufactories of carriages and waggons, reaping machines, ploughs, and other agricultural implements, sashes and blinds, railroad supplies, and machinery. Hamilton received a municipal charter in 1853, at which time the portion on the west side of the river formerly called Rossville was incorporated with it. The population, which in 1860 was 7223, and in 1870 11,081, of whom 3062 were foreigners, was estimated in 1879 at 17,000.

HAMILTON, the principal town in the western district of Victoria, Australia, is situated on the Grange Burne Creek, in 37° 48' S lat and 142° 1' E long. It was proclaimed a borough in 1859, the area of the municipality being 5280 acres. It has several elegant buildings—a hospital and benevolent asylum, a town-hall, a treasury and land office, and a public library. Its educational

institutions include the Hamilton and western district college, the academy, and the Alexandra college for ladies, besides a state school with accommodation for 500 pupils. It possesses a fine race course covering 120 acres, and pastoral and agricultural exhibitions are held annually, the surrounding district being chiefly devoted to sheep-farming. The population of the town and suburbs on the 1st January 1879 was estimated at 4400. The railway from Melbourne to Portland passes through the town.

ALEXANDER HAMILTON

Copyright, 1880, by George Shea

ALEXANDER HAMILTON, the ablest American jurist and statesman of the early constitutional era of the United States, was born at the island of Nevis, one of the Antilles under the dominion of England, on January 11, 1757. His father was a Scotch emigrant who had settled at St Christopher, where he engaged in mercantile business. His mother was the daughter of a Huguenot named Faucette, a prosperous physician of Nevis. She had been the wife of a Mr Irvine, also a physician, and during a brief married life dwelt at St Christopher, but, owing to family of his, she appears to have been driven to procure the judicial dissolution of the marriage, after which she returned to her father's home at Nevis, and there married James Hamilton. She bore to him many sons, of whom none but Thomas and Alexander lived to maturity. Alexander, the youngest, was called after his paternal grandfather, who described himself "of Gungah," which is said to have been the family seat in Ayrshire, Scotland. The master of Gungah married, in 1730, Elizabeth, eldest daughter of Sir Robert Pollock, and young Hamilton, when he had risen to fame and station, said, "My blood is as good as that of those who plume themselves upon their ancestry." He styled his suburban residence, near New York, "the Gungah."

His mother died while he was still a child, but not before he was capable of receiving and preserving distinct recollections of her. He derived from her an independent spirit, energy, self-reliance, and a disposition for metaphysical inquiries, and these qualities were conspicuous from an early age. His father's business misfortunes casting the boy upon the care of some of the mother's relatives, he was taken by them to their home at St Croix, and there at school he first evinced that proficiency which marked him throughout his career. The opportunities for school training were at that time very limited at St Croix, and when, in his thirteenth year, he entered the counting-house of Mr Nicholas Cugler, at that post, he had already received all the benefit such schools were able to impart. This was in the autumn of 1769. In less than a year he was capable of more than clerical duty, and Mr Cugler, going on a foreign journey, left him in sole charge of the mercantile house. His business correspondence during this time, and the prosperity which attended the affairs, show that Mr Cugler's confidence was not misplaced. This practical acquaintance with mercantile affairs was to be most serviceable to Hamilton. In the methodical and energetic management of matters of state, and in the prudent care of weighty interests, the influence of the knowledge and experience acquired by him in the counting-house at St Croix is notable. During these three years he was the same close student that his after years more fully reveal. He read standard books, which laid open the theories of value and of trade, thinking out to feasible methods how those theories might be advantageously applied to the daily work he had in hand. He read history, poetry, and philosophy. The French language became familiar to him by its general use in society and in the transactions of commerce, and he

always wrote it with accuracy and elegance, and spoke it fluently and with the accent of native speech. The Rev Hugh Knox, D.D., an Irishman, a divine of the Presbyterian Church, a scholar of distinction honoured as such by the university of Glasgow, was Hamilton's first adequate preceptor, and was the first to discover the rich resources and useful tendencies of his intellectual and moral character. Under his friendly and gratuitous tutelage Hamilton applied many pains in which his education was deficient. But the boy had aims beyond where he was, and when an incident, trivial in itself, led to an arrangement by which a more liberal education was opened to him, he left the West Indies, in October 1773, and proceeded to New York. There, aided by letters from his friend Dr Knox, he made the acquaintance of some of the leading men in that and the adjoining province of New Jersey. A year at the grammar school at Elizabethtown in the latter province proved sufficient to prepare him for the collegiate course, and in the spring of 1774 he entered as a student the King's (now Columbia) College, and, by special privilege, pursued the usual studies according to a plan which he laid out for himself.

When, in 1774, the enforcement of the Boston "Port Bill" aroused even the most moderate in the other colonies to sympathy with the province of Massachusetts Bay, Hamilton studied the political questions relating to the controversy between the colonies and the parliament of England with his habitual research and enlightened reasoning. He was convinced that his duty as an Englishman required him to take part with the colonists against the assertion of the "omnipotence of parliament." The famous tract by Lord Somers entitled *The Judgment of whole Kingdoms and Nations, &c*, which repudiates this as a thing unknown to the law of England, was republished in 1773 at Philadelphia, and widely circulated throughout the provinces, in aid of the cause of colonial resistance. Its effect upon the mind of Hamilton is to be observed in his writings of this time. With his usual ardour he now busied himself in public discussion. Before his eighteenth year ended his reputation as an orator and writer was established. His chief opponent at this period was the distinguished divine Samuel Seabury, who a few years later (1783) was consecrated in Scotland the first bishop of the United States of America. The fame of their debates spread over the whole country, and Hamilton was the acknowledged "oracle" of the party of moderation, with which he acted.

While still a collegian he joined the military of the province of New York, and began as the captain of its first company of artillery employed in the continental service. To qualify himself for such a position he had, under the immediate instruction of an experienced soldier and officer, not only studied the theoretic art of war but engaged with others in receiving daily for several months practical lessons in the field-drill. He was active with his company of artillery at the battle on Long Island, at Harlem Plains, at Chatterton's Hill, New Brunswick, Trenton, and Princeton. At Harlem Heights he first attracted the attention of Washington, and again at New Brunswick excited the commander's admiration by the courage and skill with which he held in check the advance of the British forces, while the American army was retreating toward the Delaware. When the army went, in January 1777, into winter quarters at Morristown, Hamilton, now grown in the friendship and confidence of Washington, resigned his command, became Washington's private secretary, and was raised to the rank of lieutenant-colonel. Hamilton remained on the staff until April 1781, when an unusual and hasty warmth of temper on both sides led to the severance of this particular connexion, but their mutual friendship remained

and even increased. He was married in 1780 to Elizabeth, second daughter of General Philip Schuyler, a distinguished soldier and statesman of the Revolution. For a brief space Hamilton occupied his time in exposing the inherent defects of the existing confederation by a series of excellent papers known as *The Continentalist*. But the country once more needed his more active aid, he returned to the army, led one most brilliant attack, and was present with a command at the surrender of Lord Cornwallis.

The war to maintain the declaration of independence was fought, but it did not make nor leave the United Colonies a nation. A new system of government and "a coercive union" were insisted upon by Hamilton and other foremost men as necessary. But many obstacles stood in the way. Historical prejudices and the selfishness of local interests were against concessions to a union of the States. Traditional dread of centralized government, traditional dread of an hereditary aristocracy, dread that a national legislature, if allowed full authority, might assert and act upon the repudiated doctrine of an omnipotence of parliament, dread that a supreme general government might absorb, or even usurp, under the plea of care for the public welfare, those local interests which the States were now able to maintain, and which the Confederation was meant to protect—the concurrence of these several causes contributed to bring out opposition whenever a more perfect union was proposed.

The first suggestion towards the establishment of an adequate and permanent government came, as it is now conceded, from Hamilton. It was contained in a letter written by him, September 8, 1780, to James Duane, a delegate from New York to the Congress at Philadelphia. He wrote a yet more remarkable letter the following year (April 30) to Robert Morris, the famous financier of the Revolution, in which not a mere suggestion but a matured and complete scheme of national finance, including a plan for a United States bank, was discussed and laid out. These letters are, indeed, the *princeps* of the American government in its organization and administration. When the convention of delegates met at Annapolis, Maryland, in September 1786, the influences of Hamilton upon the destinies of his country began to be favoured by circumstances. Although the object of that convention was limited to simply commercial projects, yet, under his and Madison's prudent management, an address was finally issued which brought about the great and conclusive convention of 1787 at Philadelphia. The form of government then instituted is, in its groundwork and its principal features, a restoration and perfecting of the ancient constitutional liberties of England. While the particular plan proposed by Hamilton was, as were other projects, laid aside, yet it was the spirit of the system conceived by him which then prevailed and has since been a controlling principle in the administration of government. Guizot said of him that "there is not in the constitution of the United States an element of order, of force, of duration, which he did not powerfully contribute to introduce into it and to cause to predominate." It was at this period that Hamilton, in association with John Jay and James Madison, wrote his parts of *The Federalist*.

At the convention, called by the State of New York, which met at Poughkeepsie, on the Hudson River, June 1788, to ratify the proposed National Constitution, the superb ability of Hamilton for organizing and leading intelligent public opinion displayed itself fully. The utility of candid, earnest, reasonable debate has seldom been more approved by its results. A most disheartening minority of the delegates when the convention first met were in favour of the Constitution. When Hamilton ceased his

efforts, not only had he gained to his support a majority, but even ultimately he had the aid and vote of his most eloquent and most powerful antagonist. At length Hamilton arose in the convention, and, stating that Virginia had ratified the Constitution, and that the Union was thereby an accomplished fact, moved that they cease their contentions and add New York to the new empire of republican states. That day his labours culminated in entire success.

Washington, when forming the cabinet for his first presidential administration, naturally turned to Robert Morris as the proper person to take the secretaryship of the treasury, but Morris declined, insisting that Hamilton was "the one man in the United States" fitted by studies and ability to create a public credit and bring the resources of the country into active efficiency. Washington found his former military secretary more than equal to the task. The fiscal affairs of the country were at once organized, and prosperity quickly came. Hamilton achieved an immediate success which all agree is without parallel. He also was really the organizer of the administration of the new Government, and in its chief department it remains to this day without change. His state papers, written during the two presidential terms of Washington, are regarded as of the highest character for knowledge of the case, wisdom, and practical method, and his report on the constitutionality of a national bank, in which he fully develops his favourite policy of the enlarged powers of the Government, and the other report, nominally upon manufactures, which embraces in its range every pursuit of human industry susceptible of encouragement under such a government as he wished to see that of the United States, are those productions in which the rare qualities of his mind abundantly manifest their force and precision. President Van Buren declared the latter paper to be "Hamilton's masterpiece."

After these labours Hamilton, though offered the position of chief-justice of the United States, remained at the bar of his adopted State. He soon rose to its highest rank, and was esteemed its unrivalled leader. As a citizen, and without the claims of public office, he continued always actively interested in public affairs. His intense and uncompromising moral nature engendered many political antipathies, though personally few were more loved for amiability and respected for their honour. Among those men whom he deemed it a patriotic duty to defeat in a personal ambition was Aaron Burr, the vice-president of the United States. Party lines were marked and party spirit fierce. Burr appreciated what would be the effect of Hamilton's continued opposition to his political designs, and knew that he was a man to be neither conciliated in this respect or outmanoeuvred. He eagerly watched for an opportunity to impute offence. A trivial and undignified occasion soon came. An indiscreet person repeated a remark which he said Hamilton made in a familiar conversation at the house of a common friend, to the purport that he had a "despicable" opinion of Burr. Upon this gossip Burr acted, and so subtle was the manner with which he managed the correspondence for his determined purpose that he, according to the tone of society at that time, made it, in Hamilton's misconception, an obligation, due to his continued usefulness in public affairs, to accept a challenge. They met early on the morning of July 11, 1804, at a sequestered place beneath the hills of Weehawken, on the west bank of the Hudson River, opposite to the city of New York. Hamilton was mortally wounded at the first fire. As he fell, his own pistol was repeated discharged, and the ball struck the ground near him. He did not himself intend to fire. He died the following day, in the forty-ninth year of his age. His death was considered a national calamity. Eight of his children,

four boys and four girls, were left to his widow's care. She survived him half a century, dying at the age of ninety-seven, and during all that time she remained attired in the widow's dress of the early times.

The peculiarity of Hamilton's genius consisted of qualities which eminently distinguished him from the other great peacemakers of his time. The epithet "peacemaker" was never applicable to him, for whatever he did, even in his boyhood, was accomplished with facility, and resulted in a perfection that the works of fifty years did not exceed. He was even mature. His intellect passed through the most subtle and profound problems, and apparently without the least effort. He "could see consequences yet down into their principles," as Mr. Tully said of him on more than one occasion, "he divined." "Hamilton was divine," says the person given by his name, who compared him to Eve and Napoleon. His industry was marvellous, and his learning equal to the creative faculty of his mind. The fecundity, power, vigour, and fertility of his intellectual works is fully attested by his writings, not those contained in *The Liberator*.

His political writings, seen in the estimation of judicious and eminent writers in America, Great Britain, and France, to place him in the first rank of political writers. The most widely known of these writings are those contained in *The Liberator*. A translation of them was published in Paris (the first as early as 1792), and was studied by the chief public men of that period. It has been noted that it exerted an event and pervasion of information, a profundity of view, and an acuteness of understanding which would have done honour to the most illustrious statesmen of ancient or modern times, that for comprehensiveness of design, strength, clearness, and simplicity they have no parallel (*Select Essays in American Literature*, January 1836, and *The Liberator*, Boston, No. 2). It drew and called the attention of European statesmen to the merits of *The Liberator* as a copious source of correct views and profound thought, and Gauray says that, "in the application of democratic principles to practical administration, it was the greatest work known to him." Laboulaye has observed at great length his duties to judgment of Hamilton's genius and wisdom, and of the consequences of his political views, and has organized a new system of government and organized its administration (*Histoire des États-Unis*, tome vi.). And Hamilton's own countrymen have not been less emphatic in grateful acknowledgment, especially Charles Sumner, and the great statesmen and exponents of the principles of the American Constitution.

In person Hamilton was below the medium height, slender, almost delicate in frame, insistent with life, sweet and quick in gait, his general address was so graceful and nervous, indicating the energy, civility, and activity of his mind. His complexion was bright and ruddy, his hair light, and the whole countenance decidedly Scottish in form and expression. His political opinions frankly spoke of his humane and conservative, and regarded its inevitable chain. The great poets of his age by Thackeray, Waverley, Ames, and there is a good poet by Chaucer.

For full notice of Hamilton, see the *Edinburgh Life*, in 7 vols. by John Chalmers Hamilton, one of his sons, New York, 1837, the *Life* by Dr. Renwick, published in *Harper's Family Library*, *Life by Mary*, 2 vols., Boston, 1874, *Edmund Randolph's History des États-Unis*, tome vi., 1836, *The History of the United States of the United States*, 2 vols., New York, 1838. *Reithmiller's Hamilton and his Contemporaries*, in 4 vols., London, 1864, *Hamilton's History of the United States*, in the 7th and increasing vols., and *Shaw's Life and Speeches*, ed., New York, 1880 (2 681).

HAMILTON, ANTHONY or ANTOINE (1646-1720), a French classical author, who is especially noteworthy from the fact that, though by birth he was a foreigner, his literary characteristics are more decidedly French than those of many of the most indubitable Frenchmen. His father was George Hamilton, younger brother of James, second earl of Albemarle and head of the family of Hamilton in the peerage of Scotland, and sixth duke of Châtellault in the peerage of France, and his mother was Mary Bates, sister of the duke of Ormonde. He was born in 1646, but the place of his birth has not been ascertained. According to some authorities it was Drogheda, but according to others it was Tipperary county. From the age of four till he was fourteen the boy was brought up in France, whither his family had removed after the execution of Charles I. The fact that, like his father, he was a Roman Catholic, prevented his receiving the political promotion he might otherwise have expected on the Restoration, but he became a distin-

guished member of that brilliant band of countrymen whose most fitting patriotism was destined to be the product of his pen. His connexion with France was always maintained, and the marriage of his sister to the Comte de Gramont rendered it more intimate if possible than before. On the accession of James he found his religious disabilities transformed into advantages. He obtained an infantry regiment in Ireland, and was appointed governor of Limerick. But the battle of the Boyne, at which he was present, brought disaster on all who were attached to the cause of the Stewarts, and before long he was again in France—an exile, but at home. The rest of his life was spent for the most part in the chattering of his friends. With the duc de Luvois de Maine he became an especial favourite, and it was at his seat at Sceaux that he wrote the *Mémoires* that made him famous. The ill-advised expedition of 1708 was the last political enterprise in which he shared, and he died at St Germain en Laye, August 6, 1720.

It is usually, as has already been indicated, by the *Mémoires de Comte de Gramont* that Hamilton takes rank with the most direct writers of France. The work was first published anonymously in 1719 under the name of Cologne, but it was long printed in Holland, at that time the great printers of all Europe. An English translation by Dr. Gauray appeared in 1774. Upwards of thirty editions have since appeared, the best of the French being Remondet's (1812) and Guizot's (1859), and the best of the English Edwards's (1794), with 78 engravings, and Malleville's (1811), with 64 portraits by Beauvais and others. The original edition was reprinted by Bittern in 1870. In mention and value parity of the numerous titles which Gifford's translation of *The Thousand and One Nights* had brought into our notice in France, Hamilton wrote *Le Génie*, *Plan de l'Épique*, *Épigramme*, and *Les Quatre Persians*, which are characterized by the graceful ease of their style and the successful extravagance of their incidents. The first three tales appeared at Paris in 1760, and gave rise to the death of the author, and a collection of his *Œuvres Posthumes* in 1781 contained the unfinished "Zephyr." A collected edition of Hamilton's works was published in six volumes in 1740, and is reprinted in 1762, 1776, 1776, and 1777. A translation of Pope's *Essay on Criticism*, which secured the author's contemporary acknowledgment from the poet, is still in MSS., with the exception of a fragment printed in the 1812 edition of the works. In the name of his niece, the countess of Striford, Hamilton maintained a witty correspondence with Lady Mary Wroth Montagu. See *Notices of Hamilton* in the 1832 edition of his works, and in Leveson's edition of the *Contes*, *Sainte Beuve's Œuvres et les Érudits* (tom. i.), and *Simon's Mémoires de la Littérature française* (Paris, 1885).

HAMILTON, ELIZABETH (1758-1816), novelist and miscellaneous writer, was born at Belfast, of Scotch extraction, 25th July 1758. Her father's death in 1759 left his wife so embarrassed that Elizabeth was adopted in 1762 by her paternal aunt, Miss Marshall, who lived in Scotland, near Stirling. There Elizabeth spent her youth and received a good education,—at first at school, afterwards in private, and, lastly, for some months, under masters at Edinburgh and Glasgow. In her 16th year she made a tour in the Highlands with some friends, and wrote a journal of it for her aunt's personal, which was inserted, unknown to the authoress, in a provincial magazine. In 1780 Miss Marshall died, and Miss Hamilton was prevented by household cares from using her pen, but in 1785 she made her first voluntary contribution to the press in the shape of a letter to the *Lounger*, of which paper it forms the 46th number. On the death of Mr Marshall in 1788, Miss Hamilton lived for a time with her brother, Captain Charles Hamilton, who was engaged on his translation of the *Hedaya*. Prompted by her brother's associations, she produced her *Letters of a Hindu to Rayah* in 1790, and some time after, with her sister Miss Blake, settled at Bath, where she published in 1800 her *Memoirs of Modern Philosophy*, a kind of satire on the manners of the French Revolution. In 1801-2 the *Letters on Education* appeared, her most valuable though not her most popular work. After travelling through Wales and Scotland

for nearly two years, the sisters took up their abode in 1803 at Edinburgh. In 1804 Mrs Hamilton, as she then preferred to be called, published her *Life of Asenpina, wife of Cincinnatus*, and in the same year she received a pension from Government. About this time she consented to take charge for six months of a widowed Scotch nobleman's family, and to his eldest daughter were addressed *Letters on the Moral and Religious Principle*, published in 1806. Her next publication of importance, *The Cottagers of Glenburnie*, appeared in 1808. This work, to which the authoress owes most of her fame, is an admirable description of the failings of the Scotch peasantry in their home life, and, while graphic and telling, is "saved from caricature and absurdity." Sir Walter Scott describes it as "a picture of the rural habits of Scotland, of staidness and impressive fidelity," and Lord Jeffrey reviewed it very favourably in the *Edinburgh Review* (vol. xii.). Her subsequent works were a supplement to her *Letters on Education*, under the name of *Popular Essays on the Elementary Principles of the Human Mind* (1813), and *Hints addressed to the Patrons and Directors of Public Schools* (1815). She died at Harrogate, July 23, 1816.

Memoirs of Mrs Elizabeth Hamilton, by Miss Tenge, were published in 1818. A notice of her literary labours, attributed to Miss Edgeworth, appeared in the *Monthly Magazine* for September 1818.

HAMILTON, JAMES (1769-1831), the author of the Hamiltonian system of teaching languages, was born in 1769 and died October 31, 1831. The first part of his life was spent in mercantile pursuits. Having settled in Hamburg and become free of the city, he was anxious to become acquainted with German and accepted the tuition of a French emigré, General d'Anglais. In twelve lessons he found himself able to read an easy German book, his master having dissected the use of a grammar and translated to him about sixteen words for word into French. A citizen of Hamburg Hamilton started a business in Paris, and during the peace of Amiens maintained a lucrative trade with England, but at the rupture of the treaty he was made a prisoner of war, and though the protection of Hamburg was enough to get the words *écrit de la liste des prisonniers de guerre* inscribed upon his passport, he was detained in custody till the close of hostilities. His business being thus ruined, he went in 1814 to America, intending to become a farmer and manufacturer of potash, but changing his plan before he reached his "location," he started as a teacher in New York. Adopting his old tutor's method, he obtained remarkable success in New York, Baltimore, Washington, Boston, Montreal, and Quebec. Returning to England in July 1823, he was equally fortunate in Manchester and elsewhere. His system attracted general attention, and was vigorously attacked and defended. In 1826 Sydney Smith devoted an article to its elucidation in the *Edinburgh Review*—"We are strongly persuaded," he said, "that, the time being given, this system will make better scholars, and the degree of scholarship being given, a much shorter time will be needed" than in the ordinary system. As text-books for his pupils Hamilton printed interlinear translations of the Gospel of John, of an *Epitome of Aristotle's works*, of *Esop's Fables*, Euripides, Amelius Victor, Phœdrus, &c., and many books were issued as Hamiltonian with which he had nothing personally to do. The two master principles of his method, which has left its traces on our modern linguistic discipline, are that the language is to be presented to the scholar as a living organism, and that its laws are to be learned from observation and not by rules.

See Hamilton's own account—*The Principles, Practice, and Results of the Hamiltonian System for the last Twelve Years*, Manchester, 1828. *Albert, the Hamiltonian's Methods*, O. F. Wurm, Hamilton and Jacob, 1281.

HAMILTON, PATRICK (1504-1528), son of Sir Patrick Hamilton, well known as Scottish clergyman, and of Catherine Stewart, daughter of Alexander, duke of Albany, second son of James II of Scotland, was born in the diocese of Glasgow, probably at his father's estate of Stonehouse in Lanarkshire. Of his early boyhood and education nothing is known. In 1517 he was appointed titular abbot of Feme, Ross-shire, and it was probably about the same year that he went to study at Paris, for his name is found in an ancient list of those who graduated there in 1520. It was doubtless during this period that he received the germs of the doctrines he was afterwards so nobly to uphold. From Ales we learn that Hamilton subsequently went to Louvain, attracted probably by the fame of Erasmus, who in 1521 had his headquarters there. Returning to Scotland, the young scholar naturally selected St Andrews, the capital of the church and of learning, as his residence. On the 9th June 1523 he became a member of the university of St Andrews, and on the 3d October 1524 he was admitted to its faculty of arts. There Hamilton attained such influence that he was permitted to conduct in the cathedral a musical mass of his own composition. But the Reformed doctrines had now obtained a firm hold on the young abbot, and he was eager to communicate them to his fellow-countrymen. Early in 1527 the archbishop Beaton's attention was directed to the heretical preaching of the young monk, who engaged to be ordered that Hamilton should be formally summoned and accused. Hamilton fled to Germany, first visiting Lutetia at Witteberg, and afterwards enrolling himself as a student, under Francis Lambert of Avignon, in the new university of Marburg, opened May 30, 1527, by Philip, landgrave of Hesse. Frith and Tyndale was among those whom he met there. Late in the autumn of 1527 Hamilton returned to Scotland, bold in the truth of his principles. He went first to his brother's house at Kincauld, near Lunthgow, in which town he preached frequently, and soon afterwards he married a young lady of noble rank, whose name has not come down to us. Beaton, avoiding open violence through fear of Hamilton's high connexions, invited him to a conference at St Andrews. The reformer resolutely accepted the invitation, and for nearly a month was permitted to preach freely. At length, however, he was summoned before a council of bishops and clergy presided over by the archbishop, and though he clearly and calmly answered all the written charges brought against him, his replies gave ground for new accusations of heresy. The council eagerly convicted him, and handed him over to the secular power. The sentence was carried out on the same day (February 28, 1528) lest he should be rescued by his friends, and he was burned at the stake as a heretic. His courageous bearing attracted more attention than even to the doctrines for which he suffered, and greatly helped to spread the Reformation in Scotland.

Hamilton left a short treatise showing the antithesis between the law and the gospel. The translation of it, under the name of "Patrick's Phœnix," is to be found in *Foxe's Acts and Monuments*. *Patrick Hamilton, the first Preacher, and Martyr of the Scottish Reformation*, by Rev. Peter Laumer, was published at Edinburgh in 1867.

HAMILTON, ROBERT (1743-1829), an able writer on political economy and finance, was born at Pilton, Edinburgh, on the 11th June 1743. He was of good family, his grandfather, William Hamilton, professor of divinity and afterwards principal of Edinburgh University, having been a member of the family of Pilton. He received an excellent education, and specially distinguished himself in the classes of mathematics at the university of Edinburgh, then under Professor Matthew Stewart. Although desirous of following a literary life, he was induced to enter the banking-house of Messrs Hogg in order to acquire a prac-

tical knowledge of business. In 1766 he was disappointed in his efforts to obtain the mathematical chair at Aberdeen university, but three years later he gave up business pursuits and accepted the rectorship of Peith academy. In 1779 he was presented to the chair of natural philosophy at Aberdeen university. For many years, however, by private arrangement with his colleague Professor Copland, Hamilton taught the class of mathematics. In 1817 he was presented to the latter chair. For some years before his death in July 1829 he had retired from the active business of his chair, and quitted his privacy only at rare intervals to take part in important affairs concerning the college.

Hamilton's most important work is the *Essay on the National Debt*, which appeared in 1813 and was undoubtedly the first to expose the economic fallacies involved in Pitt's policy of sinking fund. It is still of value. A posthumous volume published in 1830, *The Progress of Society*, is also of great ability, and is a very able, (rare) treatise of economical principles by tracing their natural origin and position in the development of social life. Some minor works of a practical character (*Introduction to Macaulay's*, 1778, *Essay on War and Peace*, 1790) are now forgotten.

HAMILTON, THOMAS (1789-1842), the author of *Cyril Thornton*, was the younger brother of Professor Sir William Hamilton, Bart., and was born in 1789. In his early years he acquired a thorough mastery of the classics, and notwithstanding that he entered the artillery and was engaged in active service throughout the Peninsular and American campaigns, he continued to cultivate his literary tastes. On the conclusion of peace he withdrew, with the rank of captain, from active professional duties, and amused his leisure hours with the congenial pastime of literature. He was a frequent contributor to *Blackwood's Magazine* from its commencement, his papers manifesting great variety and versatility of talent, and embracing both prose and poetry. The most important and popular of his contributions to that periodical was the military novel *Cyril Thornton*, whose deficiency of plot is sufficiently compensated for by the interest of its details, its vivacity of movement, its truthful and clear delineation of character, and its easy, fresh, and graceful style. His *Annals of the Peninsula Campaign*, published originally in 1829, and republished in 1849 with additions by Frederick Hardman, though too condoned to leave room for graphic description, is written with great clearness and impartiality. His only other work, *Manners and Customs in America*, published originally in 1832, is the result of much careful observation, and its criticisms, though frank and outspoken, and somewhat coloured by British prejudices, are always expressed with courtesy and good taste. He died at Pisa, December 7, 1842.

HAMILTON, SIR WILLIAM, BART. (1788-1856), one of the most eminent of Scottish metaphysicians, was born in Glasgow, on the 8th March 1788. His father, Dr William Hamilton, had in 1781, on the strong recommendation of the celebrated William Hunter, been appointed to succeed his father, Dr Thomas Hamilton, as professor of anatomy in the university of Glasgow, and when he died in 1790, in his thirty second year, he had already gained a reputation that caused his early death to be widely and deeply regretted. William Hamilton and a younger brother (afterwards Captain Thomas Hamilton, noticed above) were thus brought up under the sole care of their mother,—a woman, fortunately, of considerable ability and force of character. William received his early education in Scotland, except during two years which he spent in a private school near London, and went in 1807, as a Snell exhibitioner, to Balliol College, Oxford. There he pursued his studies zealously, though for the most part independently,—devoting himself chiefly to Aristotle, but in other directions also laying the foundations of that wide and profound scholarship with which his name is associated. In

November 1810 he took the degree of B.A. with first class honours, after an examination so much above the usual standard in the number and difficulty of the works which it embraced that the memory of it was long preserved at Oxford. He had been intended for the medical profession, but, soon after leaving Oxford, gave up this idea, and in 1813 became a member of the Scottish bar. Henceforward Edinburgh was his place of residence, and, except on occasion of two short visits to Germany in 1817 and 1821, he never again quitted Scotland. Neither his ambition nor his success was such as to absorb his time in professional pursuits.

His life was mainly that of a student, and the following years, marked by little of outward interest, were filled by researches of all kinds, through which he daily added to his stores of learning, while at the same time he was gradually forming his philosophic system. The outward and visible traces of these researches remain in his common-place books, especially in one which, having been in constant use, is a valuable record of his studies from this time onwards to the close of his life. He did not withdraw himself from society, but his favourite companions were the books of his own and of every library within his reach. Among these he lived in a sort of seclusion, from which only now and then, when stirred by some event of the world around, did he come forth, in vigorous pamphlets, to denounce, or protest, or remonstrate, as the case might be.

His own investigations enabled him to make good his claim to represent the ancient family of Hamilton of Preston, and in 1816 he took up the baton, which had lain dormant since the death (in 1701) of Sir Robert Hamilton, well known in his day as a Covenanter leader.

In 1820 he was an unsuccessful candidate for the chair of moral philosophy in the university of Edinburgh. Soon afterwards he was appointed professor of civil history, and as such delivered several courses of lectures on the history of modern Europe and the history of literature. In 1829 his career of authorship began with the appearance of the well known essay on the *Philosophy of the Unconditioned*,—the first of a series of articles contributed by him to the *Edinburgh Review*. He was elected in 1836 to the Edinburgh chair of logic and metaphysics, and from this time dates the influence which, during the next twenty years, he exerted over the thought of the younger generation in Scotland. Much about the same time he began the preparation of an annotated edition of Reid's works, intending to annex to it a number of dissertations. Before, however, this design had been carried out, he was struck with paralysis of the right side, which seriously crippled his bodily powers, though it left his mind wholly unimpaired. The edition of Reid appeared in 1846, but with only seven of the intended dissertations,—the last, too, unfinished. It was Sir William's distinct purpose to complete the work, but this purpose remained at his death unfulfilled, and all that could be done afterwards was to print such materials for the remainder, or such notes on the subjects to be discussed, as were found among his MSS. Considerably before this time he had formed his theory of logic, the leading principles of which were indicated in the prospectus of "an essay on a new analytic of logical forms" prefixed to his edition of Reid. But the elaboration of the scheme in its details and applications continued during the next few years to occupy much of his leisure. Out of this arose in 1847 a sharp controversy with the late Professor De Morgan of University College, London. The essay did not appear, but the results of the labour gone through are contained in the valuable appendices to his *Lectures on Logic*. Another occupation of these years was the preparation of extensive materials for a publication which he designed on the personal history, influence, and opinions of Luther. Here he

facts—but only as facts—clear and certain, and as cognitions relative, never properly judged, but as cognitions.—Hamilton claims for all that, on the sole authority of consciousness, they be accepted as truths. This is the point to which the whole of his philosophy leads up, hence he offers no arguments in its support. He only says,—If the authority of consciousness be disallowed, what other source of truth remains? Where else will a source of certainty be? He saw no alternative between absolute scepticism and implicit reliance on consciousness. But his reliance was no absolute and blind belief. He claimed implicit reliance for consciousness only after having investigated and laid down the conditions of its truth. The whole of his next part is to have a mark of truth must be proved to be that which springs from the fundamental character of the cognition. While the establishment of principles on which belief may be based, rational, and consistent is the ultimate aim of his philosophy, groundless and inconsistent belief he sweeps away wherever he meets with it. Thus he will not allow the validity of belief in an external reality which, *ex hypothesis*, is not known! Be it noted too, that it is conscious laws, not reason, for which he claims supreme authority. His position is best understood through the mutual relation (hardly noticed) of his doctrines of the conditioned and of common sense. The former attacks the bounds of evidence as much as it purveys those of thought, and so makes room for belief. Hamilton says belief to be the condition on which alone even primary and fundamental truths can be apprehended. Thus, for example, on the ground of both, he held this freedom of will and necessity as alike impossible, but that we are not entitled to reject the testimony of consciousness to the fact that as moral agents we are free, on account of the speculative difficulties with which it is surrounded. These two doctrines Sir W. Hamilton did not himself apply to theology, but he may as well not theologize if he is not being, since the one is concerned with the infinite and the absolute merely as nature, and the other with simple forms of thought long prior to those of theology. If his references to this subject indicate clearly what he considered to be the true relation of thought to philosophy, and show that, in the one as in the other, he held wisdom to lie in such a conviction of human ignorance as disposes the mind to accept testimony with the facts of consciousness as evidence of truth.

Of the three classes into which, as we have seen, Hamilton divided mental phenomena, the third—the phenomena of emotion—is not treated in his *Lectures*, and his views on this subject are fragmentary discussions of practical ethical points. Several lectures, however, are devoted to the consideration of the phenomena of feeling and the development of a theory of pleasure, founded chiefly on that of Aristotle, which is in substance that pleasure is the relief in consciousness of the spontaneous and unimpeded exercise of power or energy,—pain being, on the other hand, the consciousness of unachieved or repressed exertion.

The logic with which Sir W. Hamilton's name is associated is a purely formal science. Nothing else indeed did he consider properly to be called logic. For it seemed to him an unscientific mixing together of heterogeneous elements to treat as parts of the same science the formal and the material, the logical and the psychological. He was quite ready to allow that on this view logic cannot be used as a means of discovering or guaranteeing facts, even the most general, and expressly avowed that it has to do, not with the objective validity, but only with the mutual relation of judgments. His further held that induction and deduction are correlative processes of formal logic, each resting on the necessities of thought; and deriving thence its several laws. In establishing the distinction between logical and scientific induction, he showed that deduction no more than induction is self-sufficient, since it also must have a prior process to start from before it can be applied to nature. He also held that no other than the logical can be distinguished from the body of the sciences. Perhaps he may have too much overlooked the fact that the search for causes (a problem common to all the sciences) and the presumable uniformity of nature (a principle capable of guaranteeing general inferences of the conditions of a logic entitled to the name of science of judgments, and possessing all the importance of the knowledge whose organon it is. Yet it is well to be reminded by a difference of name that a science such as this, consisting of inferences from the natural order of things, is quite distinct from the body of truths developed from the conditions of thought as such.

The only logical laws recognized by Hamilton were the three axioms of identity, non-contradiction, and excluded middle, which he regarded as necessarily inferences of one general condition of the possibility of existence, and, therefore, of the law of the reason and consequent he considered not as different, but merely as expressing metaphysically what these express logically. He added as a postulate,—In the history was of importance,—that logic be allowed to state explicitly what is thought implicitly.

The changes by which he to a great extent remodelled formal

logic, were the result (1) of applying to propositions and syllogisms the two aspects of notions as wholes,—*extension*, viewing to the objects denoted, and *intension*, attending to the attributes connected, and (2) of assigning quantity to the predicate as well as to the subject in judgments of extension. These judgments were the form of an equation. Only simple extension is allowed, but all propositions being shown to be capable of simple extension, the class of univocal sentences is greatly narrowed. Univocal syllogisms (inductive and deductive) may be either univocal or singular, according to the distinction of subject and predicate and the distinctions included in that as or not recognized. Univocal syllogisms, but not one form, singular syllogisms of three terms, according to the position of the middle term in the premises, of these the first corresponds to the first and fourth figures of ordinary logic,—the moods of the latter being shown to be mildly induct in terms of moods of the first. The laws of categorical syllogism are reduced to one. On the other hand, one of the results of the quantification of the predicate, being to increase the number of propositional forms, a number of new moods are added, and each figure contains twelve. Hypothetical and disjunctive inferences, which are regarded as meretricious as univocal etc.—(as to this Hamilton varied in opinion, *cf. Lects.*, i. 369, 371, 373, 374),—form a separate class of syllogisms,—the conditional, properly subdivided into conjunctive and disjunctive, for, according to Hamilton, as all inference is hypothetical, this term ought not to be used as the name of one particular group. The quantities allowed by him in logic were but two—the definite, including the universal and singular, and the indefinite. The latter also he considered to be useful,—particularly as, such when the universal, both affirmative and negative, is excluded, and particularity which includes only one universal extreme, may possibly "shunt" the other. All these improvements were combined with a retention that clearly and commendably presents to the eye the whole logical scheme.

Even from this imperfect outline of Hamilton's system of psychology, metaphysics, and logic it appears how extensive and original was his labours in the various departments of philosophy, how powerful an impetus he gave to speculation, and how much he himself contributed to the elucidation of the ultimate problems of thought. By his thorough going analysis of consciousness and of the relation of consciousness to mind he did much to promote the scientific study of psychology in his own country and in America,—an impetus to give it at once a sound method and a well defined sphere. He did not himself trace the growth of consciousness, but, by showing that it is both simple and complex, both involving and evolved, he implied that it had grown, and suggested the problem of the conditions of its development. On the other hand, to him there was a wide gulf between mental and material phenomena, and the acceptance of innate ideas was attended with no difficulty, thus his point of view is so far removed from that of most of the psychologists of the present day that probably his influence now is much less either than it was in his own lifetime or than it may be hereafter.

In metaphysics his place is plainly marked. Taking his stand as once on the exclusive authority and on the limited sphere of human consciousness, he comes into direct antagonism with all schools of philosophy that find in the *Unconditioned* a field for speculation. At the same time he is divided from scepticism by his assertion that, as the realm of existence transcends that of thought, so belief is wider than knowledge, and from empiricism by his admission of *a priori* and inexplicable cognitions. He ranked himself among the Scottish school of philosophers, yet there he stands by himself, since even those doctrines which he held in common with his predecessors he held after a fashion widely different as to both grounds and results. The doctrine of common sense, in particular, he set in a new light, rescued from misapprehension, and showed, on the testimony of every school of thought, to be one of the most widely recognized of philosophic tenets. In Reid he found a philosopher to whom by many ties of intellectual affinity he was bound, and who seemed to him to have so unskilfully used the right clue to a solution of the problems

with which he dealt as to justify the doubt whether he really had it. Hence he made Reid's writings, as it were, his own, corrected his errors, and gave a solid basis to the theory which he had himself failed even to make plain.

The philosopher to whom above all others he professed allegiance was Aristotle. His works were the object of his profound and constant study, and supplied in fact the mould in which his whole philosophy was cast. With the commentators on the Aristotelian writings, ancient, mediæval, and modern, he was also familiar, and the scholastic philosophy he studied with ease and appreciation at a time when it had hardly yet begun to attract attention in his country. His wide reading enabled him to trace many a doctrine to the writings of forgotten thinkers, and nothing gave him greater pleasure than to draw forth from their obscurity, and to give due acknowledgment, even if it chance to be of the prior possession of a view or argument that he had thought out for himself. Of modern German philosophy he was a diligent, if not always a sympathetic, student. How profoundly his thinking was modified by that of Kant is evident from the tenor of his speculations, nor was this less the case because, on fundamental points, he came to widely different conclusions. There is a close likeness as to results between his system and that of Jacobi,—from which, however, his is distinguished by its more scientific character, especially by its tendency being more clearly identified with the voice of reason, and more rigidly required to prove its authority as such.

His labours in logic coincided in time with a general movement by which formal logic was effectually advanced and improved. But as to the originality of his contributions, especially in regard to the quantification of the predicate, there is no room for doubt. No evidence has ever been adduced that in the smallest degree weakens the force of the abundant evidence brought forward in its support.

Any account of Hamilton would be incomplete which regarded him only as a philosopher, for his knowledge and his interests embraced all subjects related to that of the human mind. Physical and mathematical science had, indeed, no attraction for him, but his study of anatomy and physiology was minute and experimental. In literature alike ancient and modern he was widely and deeply read, and, from his unusual powers of memory, the stores which he had acquired were always at command, every topic suggesting to him apt quotations or pertinent examples. If there was one period with the literature of which he was more particularly familiar, it was the 16th and 17th centuries. Here in every department he was at home. He had gathered a vast amount of its theological lore, had a critical knowledge especially of its Latin poetry, and was minutely acquainted with the history of the actors in its varied scenes, not only as narrated in professed records, but as revealed in the letters, table-talk, and casual effusions of themselves or their contemporaries. His article on the *Epistolæ Obscurorum Virorum*, and his pamphlet on the Disruption of the Church of Scotland in 1843, may be cited in confirmation and illustration of what has now been said. Among his literary projects were editions of the works of George Buchanan and Julius Cæsar Scaliger. His general scholarship found expression in his library, which, though mainly, was far from being exclusively, a philosophical collection. It now forms a distinct portion of the library of the university of Glasgow.

His chief practical interest was in education,—an interest which he manifested alike as a teacher and as a writer, and which had led him long before he was either to a study of the subject both theoretical and historical. He thence adopted views as to the ends and methods of education that, when afterwards earned out or advocated by him, met with general recognition, but he also expressed in

one of his articles an unfavourable view of the study of mathematics as a mental gymnastic which excited much opposition, but which he never saw reason to alter. As himself a teacher, he was zealous and successful. He did not indeed deem it necessary to give to his lectures the elaboration and precision that he bestowed on his published writings. But he made them sufficient for the end which they had to accomplish, he supplemented them at times by other instruction, and he strove, not only by all academic means, but also by his personal influence, to develop the speculative energy and interest of his pupils. His writings on university organization and reform had, at the time of their appearance, a decisive practical effect, and contain much that is of permanent value.

Many of his moral as well as intellectual characteristics are expressed in his writings,—the intensity and force of his nature, his tendency to be carried away by polemical ardour, his freedom from anything like pettiness, his perfect sincerity and candour. Such a reflex is at best very imperfect, but here could hardly be bettered by description, which, therefore, is not attempted.

His posthumous works are his *Lectures on Metaphysics and Logic*, 4 vols., edited by the Rev H. L. Mansel, Oxford, and Professor Vetch (*Metaphysics*, 1858. *Logic*, 1860), and *Additional Notes to Reid's Works*, from Sir W. Hamilton's MSS., under the editorship of the Rev H. L. Mansel, D.D., 1863. *A Memoir of Sir W. Hamilton*, by Professor Vetch, appeared in 1869. (H. H.)

HAMILTON, SIR WILLIAM (1730-1803), a dignitary and patron of the fine arts, was born in 1730 of a noble but needy Scottish family. Of his early life and education we know nothing beyond the fact that he was equestrian to Prince George, afterwards George III., whose foster-son he is said to have been, but in his twenty-fifth year he married a young and beautiful heiress, whose fortune placed him in affluence. In the first parliament of George III. Hamilton sat as member for Midlothian, and in 1764 he was accredited ambassador to Naples, an office which he retained till 1800. On proceeding to his post his attention and interest were at once awakened by the discoveries at Pompeii and Herculæum, and he took up the study of antiquities with ardour. The Farnesian collection of Greek and Etruscan vases, purchased in 1765, was the nucleus of a valuable collection of his own, now for the most part in the British Museum. Engravings and descriptions of the most valuable pieces are given in the famous *Antiquities Etusques, Grecques, et Romaines, tirées du Cabinet de M. Hamilton*, edited by D'Hancarville, and published at Naples in 1766-67. Hamilton also contributed liberally to the museum at Portici, and gave much attention to the MSS. and other valuable articles rescued from the buried cities, but his efforts were almost nullified by the meanness of the Neapolitan court, which was even suspicious of his real Natural history and science also were not neglected by him. Between 1764 and 1767 Hamilton paid numerous visits to Vesuvius, Etna, and the Lipari Islands, accompanied by a young artist, Pietro Fabris, who made drawings of the noteworthy objects and appearances under Hamilton's directions. The result of these excursions, first sent as letters to the Royal Society, of which he became a member in 1760, was afterwards expanded into two works,—*Observations upon Mount Vesuvius, Mount Etna, and other Volcanoes of the Two Sicilies*, published at London in 1773, and *Campagna Phlegæa*, a collection of plates illustrating the volcanic phenomena, accompanied by concise descriptions in English and French, published at Naples in 1776-77. A *Supplement to the latter* was made at Naples in 1776-77. Vesuvius in 1779. Hamilton's daughter died in 1775, and his first wife in 1782. In 1773 he was made K.C.B., and in 1791 privy councillor. His continued interest in art and antiquity is manifested by his contributions to the *Philosophical Transactions* of the Royal Society from 1767

to 1793, and to the *Archæologia* in 1777, as well as by his generosity to artists and antiquaries, such as Moirhead, Wüchelmann, and Pings. Recalled in 1800, he died April 6, 1803.

His William Hamilton's second wife, Emma Lyon or Haite, whose name is so notoriously associated with that of Nelson, was born of very humble parents at Preston in Lancashire, about April 26, 1764. Her youth was spent in domestic service, and it was first as attendant on a lady of fashion that she learned to develop her talent for singing and mimicry. Having lost this situation she became waitress in a tavern frequented by actors, and soon entered upon a gay and dissolute career. Her beauty attracted among others the painter Romney, who depicted her in no fewer than twenty-three of his works. Sir William Hamilton married her in 1791, and, going with him the same year to Naples, she speedily acquired an ascendancy over the mind of the queen, which at the instigation of Nelson she used for the advantage of the British fleet. On the death of Sir William she lived in a house at Meiton Place, provided for her by Nelson, but on his death in 1803 she soon squandered the modest fortune left her by her husband, and after being imprisoned for debt, retired with Nelson's daughter, Horatia, to Calais, where she died, January 16, 1815. Her memoirs appeared in the year of her death.

HAMILTON, WILLIAM (1704-1754), a minor Scottish poet, the author of *The Bases of Yarrow*, was born in 1704, probably at Bangour in Lunithgowshire, the second son of James Hamilton of Bangour, a member of the Scottish bar. It is supposed that he studied at the university of Edinburgh, and it is certain that he received an education which enabled him to enjoy the classical writers of Greece and Rome, and to be a congenial associate in after years with such men as Allan Ramsay and Henry Home. As early as 1724 we find him contributing to Ramsay's *Tea Table Miscellany*. In 1745 Hamilton joined the cause of Prince Charles, and, though it is doubtful whether he actually bore arms, he certainly celebrated the battle of Preston-pans in an ode beginning—"As o'er Gladsman's blood stained field." After the disaster of Culloden he lurked for several months in the Highlands, and at length escaped to France, but in 1749 the influence of his friends at home procured him permission to return to Scotland, and in the following year he obtained possession of the family estate of Bangour. In 1751 he married for the second time, but the state of his health was such that he soon afterwards went abroad, and he died at Lyons on 26th March 1754.

Hamilton has left behind him a considerable number of what we best describe as poetical effusions, many of them pleasing and useful, but none of them except the *Days of Yarrow* of striking originality. The first collection of his pieces was published without his permission or even knowledge by Foulis (Glasgow, 1748), and introduced by a preface from the pen of Adam Smith. Another edition, with corrections by himself, was brought out by his friends in 1760, and to this was prefixed a portrait engraved by Sir Robert Stirling. Though the poems have been since reprinted in Anderson's *British Poets* (vol. vi), in Shairp's *Collection of the British Poets*, and in Chalmers's *English Poets* (vol. xv), there was no separate edition between 1760 and 1860, when James Paterson edited *The Poems and Songs of William Hamilton*. This volume contains several poems till then unpublished, and presents a bibliographical introduction and life of the author.

See also James Chalmers's "Notices of Life of William Hamilton" in *Transactions of Society of Scottish Antiquaries*, vol. vi, 1831, and Charles McKerrow, *The Poetical Works of William Hamilton, with Selections from the Scottish Poets before Dryden*.

HAMILTON, SIR WILLIAM ROWAN (1805-1865), one of the really great mathematicians of the present century, was born in Dublin, August 4, 1805. His father, who was a solicitor, and his uncle (nephew of Tim), migrated from Scotland in youth. A branch of the Scottish family to which they belonged had settled in the north of Ireland in

the time of James I., and this fact seems to have given rise to the common impression that Hamilton was an Irishman.

His genius displayed itself, even in his infancy, as first in the form of a wonderful power of acquiring languages. At the age of seven he had already made very considerable progress in Hebrew, and before he was thirteen he had acquired, under the care of his uncle, who was an extraordinary linguist, almost as many languages as he had years of age. Among these, besides the classical and the modern European languages, were included Persian, Arabic, Hindustani, Sanskrit, and even Malay. But though to the very end of his life he retained much of the singular learning of his childhood and youth, often reading Persian and Arabic in the intervals of sterner pursuits, he had long abandoned them as a study, and employed them merely as a relaxation.

His mathematical studies seem to have been undertaken and carried to their full development without any assistance whatever, and the result is that his writings belong to no particular "school," unless indeed we consider them to form, as they are well entitled to do, a school by themselves. As an arithmetical calculator he was not only wonderfully expert, but he seems to have occasionally found a positive delight in working out to an enormous number of places of decimals the result of some nice income calculation. At the age of twelve he engaged Colburn, the American "calculator boy," who was then being exhibited in a captivity in Dublin, and he had not always a warm opinion of the woman. But, two years later, he had accidentally fallen in with a Latin copy of *Euclid*, which he eagerly devoured, and at twelve he attacked Newton's *Arithmetica Universalis*. This was his introduction to modern analysis. He soon commenced to read the *Principia*, and at sixteen he had mastered a great part of that work, besides some more modern works on analytical geometry and the differential calculus.

About this period he was also engaged in preparation for entrance at Trinity College, Dublin, and had therefore to devote a portion of his time to classics. In the summer of 1822, in his seventeenth year, he began a systematic study of Laplace's *Mécanique Céleste*. Nothing could be better fitted to call forth such mathematical powers as those of Hamilton, for Laplace's great work, like to profusion in analytical processes alike novel and powerful, demands from the most gifted student careful and often laborious study. It was in this successful effort to open this treasure house that Hamilton's mind received its final impulse. "Dus losz il commença à marcher seul," to use the words of the biographer of another great mathematician. From that time he appears to have devoted himself almost wholly to original investigation (so far at least as regards mathematical matters), though he ever kept himself well acquainted with the progress of science, both in Britain and abroad.

Having detected an important defect in one of Laplace's demonstrations, he was induced by a friend to write out his remarks, that they might be shown to Dr Binkley, afterwards bishop of Cloyne, but who was then royal astrolome for Ireland, and an accomplished mathematician. Binkley seems at once to have perceived the vast talents of young Hamilton, and to have encouraged him in the kindest manner. He is said to have remarked in 1823 of this lad of eighteen,—"This young man, I do not say will be, but is, the first mathematician of his age."

Hamilton's career at college was perhaps uneventful. Amongst a number of competitors of more than ordinary merit, he was first in every subject, at every examination. His is said to be the only recent case in which a student obtained the honour of an *optime* in more than one subject. This distinction had then become very rare, not being given unless the candidate displayed a thorough mastery over his subject. Hamilton received it for Greek

and for physics. How many more such honours he might have attained it is impossible to say, but he was expected to win both the gold medals at the degree examination, had his career as a student not been cut short by an unprecedented event. This was his appointment to the Andrews professorship of astronomy in the university of Dublin, vacated by Dr Brinkley in 1837. The chair was not exactly offered to him, as has been sometimes asserted, but the electors, having met and talked over the subject, authorized one of their number, who was Hamilton's personal friend, to urge him to become a candidate, a step which his modesty had prevented him from taking. Thus, when barely twenty-two, he was established at the Dublin Observatory. He was not specially fitted for the post, for although he had a profound acquaintance with theoretical astronomy, he had paid but little attention to the regular work of the practical astronomer. And it must be said that his time was better employed in grand original investigations than it would have been had he spent it in meridian observations made even with the best of instruments,—in those better than if he had spent it on those of the observatory, which, however good originally, were then totally unfit for the delicate requirements of modern astronomy. Indeed there can be little doubt that Hamilton was intended by the university authorities who elected him to the professorship of astronomy to spend his time as he thought best could for the advancement of science without being tied down to any particular branch. Had he devoted himself to practical astronomy they would assuredly have furnished him with no less instruments and an adequate staff of assistants.

In 1835, being secretary to the meeting of the British Association which was held that year in Dublin, he was knighted by the lord-lieutenant. But far higher honours rapidly succeeded, among which we may merely mention his election in 1837 to the president's chair in the Royal Irish Academy, and the rare and coveted distinction of being made corresponding member of the academy of St Petersburg. These are the few salient points (other, of course, than the epochs of his most important discoveries and inventions presently to be considered) in the uneventful life of this great man. He retained his wonderful faculties unimpaired to the very last, and steadily continued till within a day or two of his death (September 2, 1865) the task (his *Elements of Quaternions* which had occupied the last six years of his life.

The germ of his first great discovery was contained in one of those early papers which have been so much commended by those to whom, under the title of *Classics*, it was presented in 1829 to the Royal Irish Academy. It is referred as usual to a committee. This report, while acknowledging the novelty and value of its contents, and the great intellectual skill of the author, recommended that, before being published, it should be still further developed and simplified. During the next three years the paper grew to an enormous bulk, partly by the addition of details which had been omitted at the time of the committee. But it was assumed that, in its intelligible form, and the grand features of the new method were now clearly to be seen. If Hamilton himself seems not till this period to have fully understood either the nature or the importance of his discovery, it is only now that we find him expressing his intention of applying his method to dynamics. The paper was finally entitled "Theory of Systems of Rays," and the first part was printed in 1833 in the *Transactions of the Dublin Irish Academy*. The second and third parts have not yet been printed, but it is understood that their more important contents have appeared in the three voluminous supplements (to the first part) which have been published in the same *Transactions*, and in the two papers "On a General Method in Dynamics," which appeared in the *Philosophical Transactions* in 1841-5. The principle of "Varying Action" is the great feature of these papers, and it is strange, indeed, that the one pertinent result of this theory which, perhaps more than any other, has been brought to the world, has rendered his name known beyond the little world of the philosopher, should have been seen only within the reach of friends and others for many years past, and in no way required Hamilton's new conceptions of authority, although it was by them that he was

led to its discovery. This singular result is still known by the name "Conjugate Refraction," which he proposed for it when he first presented its existence in the third supplement to his *Systems of Rays*, and in 1832.

The step from optics to dynamics in the application of the method of "Varying Action" was made in 1837, and communicated to the Royal Society, in whose *Philosophical Transactions* for 1831 and 1835 there are two papers on the subject. These, however, like the "Systems of Rays," a mastery of the symbols and a great facility in mathematical language almost unacquainted. But they contain what is far more valuable still, the greatest addition which dynamical science had received since the great studies made by Newton and Lagrange. Jacobi and others in mathematics have developed it to great extent, and as a question of pure mathematics only, Hamilton's processes, and have thus made extensive additions to our knowledge of differential equations. But there can be little doubt that they have as yet obtained only a mere glimpse of the vast field of results of which they contain the germ. And though this is of course by far the most valuable aspect in which any such contribution to science can be looked at, the other must not be despised. It is only a sentence or more of Hamilton's of nearly all given observations, that even then induced consequences of it, of high value.

The other great contribution made by Hamilton to mathematical science, the invention of QUATERNIONS, is fully treated under that heading. It is not necessary to say here more than this, that quaternions form as great an advance relatively to the Calculus methods as the latter, when first propounded, formed relatively to Euclid's geometry. The following characteristic extract from a letter shows Hamilton's own opinion of his mathematical work, and also gives a hint of the devices which he employed to render written language as expressive as visual speech. His first great work, *Lectures on Quaternions* (Dublin, 1843), is almost unobtainable in consequence of the frequent use of italics and capitals.

"I hope that it may not be considered as unpardonable vanity or presumption on my part, if, in my own little life, I wish to be left a goodly interest in mathematics, which I have by my efforts, rather than by any other means, which can be aptly quoted, that I desire and hope to be remembered. Nevertheless it is only human nature, to desire some pleasure from being cited, now and then, even about 'Theorems' which I have discovered. The quote can enrich the subject, by combining it with materials of his own."

The discovery, papers, and lectures we have mentioned might well have formed the whole work of a long and laborious life. But not to speak of his enormous collection of MS. books, left behind following with new and original matter, which have been handed over to Trinity College, Dublin, and of whose contents it is to be hoped a large portion is yet to be published, the works we have already alluded to have formed the greater portion of what he has published. His extraordinary investigations connected with the solution of algebraic equations of the fifth degree, and his re-arrangement of the rules suited to it by Abel, Fourier, and Bézout, in their researches on this subject, form another grand contribution to science. These are not his great paper on *Fluctuating Functions*, a subject which, since the time of Fourier, has been of numerous and ever increasing use in physics, and in the theory of heat. There is also the extremely ingenious imitation of the HOMOGENEOUS (p. 6) Of his extensive investigations into the solution (especially by numerical approximation) of certain classes of differential equations, which constantly occur in the treatment of physical questions, only a few items have been published, at intervals, in the *Philosophical Magazine*. Besides all this, Hamilton was a voluminous contributor to a single list of his papers from fifty to a hundred or more closely written pages, all devoted to the minute consideration of every feature of some particular problem for it was one of the peculiar characteristics of his mind never to be content with a general understanding of a question, he pursued it until he knew it in all its details. He was a generous and kind in answering applications for assistance in the study of his works, even when his compliance must have cost him his valuable time. He was a deeply private and hard to please man, but his few friends of his own works for publication, and it was probably for this reason that he published so little compared with the extent of his investigations.

Like most men of great originality, Hamilton, generally in mental ideas before putting them to paper. "He used to carry on," says his elder son, "long trains of algebraical and mathematical calculations in his mind, during which he was unconscious of the earthly surroundings of his body, so used to bring his mind back to his study, but a brief rest of recognition of the intrusion of the shop or street was often the only relief, and his thoughts went on working upwards."

For further details about Hamilton (his poetry and his association with poets, for instance) the reader is referred to the *Dublin University Magazine* (Jan. 1859), the *Contemporary Review* (Jan. 1860), and the *Monthly Notices of the Royal Astronomical Society* (Jan. 1860), and also to the *Scottish Review* (Sept. 1860), from which much of the above sketch has been taken. (P. 7)

HAMIRPUR, or HUMBERPOON, a British district in the northeastern-governorship of the North-Western Provinces, India, lying between 25° 5' and 26° 10' N lat., and between 79° 22' 45" and 80° 25' 18" E long. It forms the south western district of the Allahabad division, and is bounded on the N by the Jumna (Jamunā), on the N W by the native state of Banoni and Betwa river, on the W by the Dhasan river, on the S by Alipura, Chhatrapur, and Chaikhani states, and on the E by the Bāndra district. It encloses the native states of Sarila, Jigrit, and Bihat, besides portions of Charkhi and Garmauli.

Hamirpur forms part of the great plain of Dandeldikhand, which stretches between the banks of the Jumna and the central Vindhyan plateau. The district is in shape an irregular parallelogram, with a general slope northward from the low hills on the southern boundary. The scenery is rendered picturesque by the artificial lakes of Mahoba. These magnificent reservoirs were constructed by the Chandel rajas about 800 years ago, for purposes of irrigation and as sheets of ornamental water. Many of them enclose craggy islets or peninsulas, crowned by the ruins of granite temples, exquisitely carved and decorated. From the base of this hill and lake country the general plain of the district spreads northward in an aid and treeless level towards the broken banks of the rivers. Of these the principal are the Betwa and the Dhasan, the latter, both of which are unnavigable. These little water courses, except in the ravines by the river sides. The deep black soil of Dandeldikhand, known as *mal*, retains the moisture under a dried and lifted surface, and renders the district fertile.

The census of 1872 gives a population of 520,197—278,106 males and 242,091 females. The Hindus numbered 493,877, and the Muhammadans, 89,638. The Chandel and Dandeli, the old dominant classes, have now sunk to 518 and 812 respectively, most of these situated to the northward of Malho. The se Mahomedans of the Jamna valley, who are the most numerous, form a population of more than 5000 souls—namely, Rithi, Humirpur, Mahoba, Mundha, Samsejari, and Jitpur. The staple produce of the district is grain of various sorts, the most important being cotton. Cotton is also a valuable crop, whose cultivation is on the increase. Out of a total area of 1,464,641 acres, 762,213 are under cultivation. Irrigation is practised on only 16,000 acres, chiefly in the south, where a net can be obtained from the artificial lakes. Agriculturists suffer much from the spread of the *Jam* grass, a noxious weed which overruns the fields and is found to be almost insupportable, wherever it has once obtained a footing. The district is fertile in the higher parts, but drought, and famine are unhappily common. The scarcity of 1887 and 1888-89 was severely felt in Hamirpur. Commerce is chiefly carried on by means of its great river highway, the Jumna. Cotton and grain are the chief exports, the former downwards, while rice, sugar, tobacco, and Manchester goods constitute the principal imports upwards. The manufactures consist of coarse cotton cloth and cottons ornaments. There is only one metallised road, that between Hamirpur and Nagoun, 70 miles in length. The gross revenue in 1870-71 was £181,646, exclud. mil. and £110,416. In 1871 the police force numbered 531 men, supplemented by 1953 village watchmen (*chakravatis*), maintained at a cost of £8038. The district contains only one jail, the average number of prisoners in 1860 was 400, in 1860, 72, and 1870, 120. In 1870 the number of schools was 112, with 8068 pupils, the cost, £1384. The district is divided into 8 teen divisions (*pragana*). The climate is dry and hot, owing to the absence of shade and the barrenness of soil, except in the neighbourhood of the Mahobi lakes, which cool and moisten the atmosphere. The rain fall in 1860-70 was 87, in 1870-71 88 1/2 in.

History.—From the 9th to the 14th century this district was the centre of the Chandel kingdom, with its capital at Mahoba. The district was the town with many splendid edifices, remains of which still exist, besides the famous temple of the death of the king already described. At the end of the 12th century Mahoba fell into the hands of the Mussulmans, who retained possession of it for 500 years. In 1680 the district was conquered by Chhatrar Sati, the hero of the Bundelas, who assumed it, his death one-third to his ally the peshwa of the Marhattas. Until Bundelkhand was constituted a British district in 1803, there was constant warfare between the Bundela princes and the Marhatta chieftains. The land had been much ravaged by the long wars and under Chhatrar Sati, overruled and ravaged during the Marhatta aggression,

and devastated by robber chiefs, so that in 1812 it was reported to be utterly a desolation. On the outbreak of the mutiny, Hamirpur was the scene of a fierce rebellion. All the principal towns were plundered by the surrounding native chiefs. Since then the condition of the district seems to have improved, but it has not yet recovered from the long ravages of Marhatta rule.

In Hamirpur, the administrative headquarters of the above district, in 26° 58' N lat. and 80° 11' 50" E long., is situated on a tongue of land at the confluence of the Betwa and the Jumna, on the right bank of the latter river. It was founded, according to tradition, by Hamir Deo, a Kauchul Rajput expelled from Ulwa (Alwar) by the Mahomedans. The town possesses little importance, there are no manufactures, and quite a limited trade in grain. Population in 1872, 7007.

HAMLET, the hero of Shakespeare's drama, is according to some interpreters an historical or quasi-historical personage, but according to others his story is a mere development of "precipitation" of the great Scandinavian system of mythology. The decision of this point is rendered all the more difficult as the only original authority for the facts (historical or mythological) is the Danish historian Saxo Grammaticus (d 1204). Though Dr Vigfusson (prolegomena to the *Sturlunga Saga*, Oxford, 1878) concludes that the Hamlet legend was contained in the Skjoldunga Saga now lost, it is of course matter of question whether Saxo based this portion of his narrative on previous writings or collected his material from oral tradition.

According to Saxo, whose account is excerpted in Simcock's *Quellen der Skjaldens* (Bonn, 1870), and summarized in Lehmann's *Disquisitiones on Hamlet* (Lond., 1872, reprinted from *Transactions of the Roy Soc of Literature*, vol. x, new series), Hamlet's history is briefly as follows. In the days of Ronik, king of Denmark, Gerdendill was governor of Jutland, and in this office he was succeeded by his sons Hovendill and Fengo. The former, returning with glory from a viking expedition in which he had defeated Koller, king of Norway, obtained the hand of Gerutha, Ronik's daughter, who in due course bore him a son Amleth. But Fengo, out of jealousy, murdered Hovendill with his own hand, and then persuaded Gerutha to become his wife, on the plea that he had committed the crime for no other reason than to avenge his of a husband by whom she had been hated. Amleth, afraid of sharing his father's fate, pretends to be imbecile, but the suspicion of Fengo puts him to various tests, which are related with all the inconsequent simplicity of the ordinary *Machon*. Despatched to England in company with two attendants, who bear a letter instructing the king of that country to put him to death, he assumes the purport of their instructions, and secretly modifies the inscription on their "tablets" so that the king is requested to put them to death and to treat him with honour. By his wisdom he makes a deep impression on the king, and obtains the hand of the royal princess, but instead of settling in England he returns at the end of a year to Denmark, where he is supposed to be dead, just as the people are celebrating his obsequies. During the feast that follows he makes the courtiers all drink freely, and then, when they are heavy with wine and sleep, he pulls down over them the hangings of the hall, fixes these with pegs which he had sharpened and prepared in the early stage of his folly, and then setting fire to the building leaves the revellers to their fate. He next proceeds to the royal chamber to take vengeance on Fengo himself, who falls beneath the stroke of his own sword, for which Hamlet had substituted his own scabbard. Returning to England for his wife, the hero ends that his father-in-law and Fengo had been under pledge to each other that the survivor should avenge the other's death if it resulted from violence, and his father-in-law, unwilling to make a direct attack on his life, sends

him to Scotland as proxy-suitor for the hand of a noble queen Heimthanda, who has put all previous wooers to death. But Heimthanda happens to fall in love with Hamlet, and he returns to England to upbraid his father-in-law with his treachery. As king of Judland he has to endure the grievous hostility of Vileklaus, Ronik's successor, but at last determines, though well aware that he is doomed to death in the attempt, to engage with him in a decisive battle. He perishes, and his widow marries Vileklaus.

According to Latham, who may be taken as the representative of the historical theory, there are really two Hamlets,—the Hamlet of Saxo's third book and the Hamlet of his fourth book, who have been confounded together. The former, who is the Shakespearean hero, he would identify with Olaf Kyrie, the Aulaf Gwynn of the Saxo Chronicle and the Amlof Canaan of the Irish Annals, whose name, having passed through England and Ireland, he supposes to have returned to Denmark in a form which is Latinized by Saxo as Amlethus, the latter he considers as the Hygelac of Beowulf, the Chochilaus of Gregory of Tours, the Hahlhako of the Heimskingla, and even the Havelok of English legend. "By a confusion between them as man and man, the beaoties," he says, "of names as different as Olaf and Hygelac take a form out of which Amlethus is a probable elisor." But this theory, which is expounded with more learning than lucidity, is hardly so much in favour as that of the mythological school.

That, in spite of the links by which Saxo has sought to connect its distant portions with the authentic history of Denmark, the whole story was destitute of historical basis was maintained by P. E. Müller (*Nordl. Undersøgelser af Danm. s. l. og Nørges Saghistorie eller om Trossedigheden af Saxo, og Svaris Kilder*, Copenhagen, 1823), and his conclusions in regard to the matter have been very generally accepted. Though Hamlet or Amleth himself is not mentioned in the earlier documents of the Scandinavian mythology—the only allusion to his existence being the phrase *Amleth's gnen*, or Hamlet's mill, applied to the sea in the Skaldskaparmál—his father, Hovendill or Oivandil (from *ov*, the spear, and *vandil*, skilful), appears in the great Scandinavian mythos in connexion with Thor's contest with Hrungnir, and is further to be identified with the Orendil of German legend, whose memorial coat was after wards christened the seamless coat of our Saviour at Treves, and whose name, which occurs also as Enthalhe, may possibly be the source of the more famous name of Tell. Hamlet's own name finds its explanation in the Norse *amr* or *amr*, cool (still used colloquially in Icelandic, *amla*, to cool), and *li*, *li*, devoted to, and probably has reference to his mythic impersonation of the endless toil and travail of the sea.

The various details of the story—not only improbable and impossible, but essentially stupid and trivial—lend themselves with remarkable readiness to the theory which explains them as variations of the tale, a thousand times told, of the contests between summer and winter, sea and land, light and darkness. An elaborate exposition of the whole will be found in Ziwon's *Die Hamletlegende aus und mit vorerwähnten Sagen*, eluclert, Halle, 1877. It has been already stated that Saxo's is the only original authority, but proof of the popularity of the legend is found in the presence in Ireland of such names as Amlethe (*ie*, Hamlet's Heath), near Randers, Fegges Sund, that is, Fengo's Sound, and Feggaskirk, that is, Fengo's Cliff, and in the fact that in modern Icelandic the word *amleth* is a regular equivalent for an idiotic or stupid man. Not are literary refinements of the story wanting. The Icelanders have their Amlethia Saga, which is a free translation of Saxo, and their Amlebas Saga, in which the matter is treated in a more romantic style. The story of Blinn, given in Jon Arason's *Islen. luv Þjóðsögu* (Leyssie 1804, 11), has the

same main features, and Di. Vigfússon, by whom it was discovered, is disposed to surmise that the legend may actually be of Celtic origin,—a supposition quite in keeping with other well known facts in Icelandic history. It was taken down from the lips of Lady Hildur Angimurs, doctor, whose father was born in 1568. As Niels of Sorø in the 16th century made Hamlet more familiar to the Danes by his *Danské Rimke onle*, so the French story-teller Belleforest introduced him to a wider company in his *Cest Histoire des bagues*. That as early as 1587 or 1589 he had been represented on the English stage is shown by the well-known passage from Nash's preface to Greene's *Menaphon*, "He will afford you whole *Hamlets*, I should say handfuls of tragical speeches."

HAMM, a town of Prussia, capital of a circle in the government district of Arnberg, province of Westphalia, is situated at the junction of several railways, on the Lippe at its confluence with the Aase, 22 miles N.W. of Arnberg. It is enclosed by walls, but the ditches which formerly surrounded it have been filled up and converted into promenades. The principal buildings are two Catholic and two Evangelical churches, a gymnasium, a poorhouse, an orphanage, and an infirmary. The town is flourishing and rapidly increasing, and possesses very extensive wine factories (in connexion with which there are puddling and rolling mills, tanneries, machine works, and manufactures of gloves, baskets, wadding, leather, sausages, soap, starch, chemicals, sugar-of-lead, gun, lac, varnish, oil, and beer. The population in 1875 was 18,877.

Hamm, which became a town about the end of the 11th century, was originally the capital of the countship of Alach, and was fortified in 1226. It became a member of the Hanseatic League. In 1611 it was besieged by the Dutch, and in 1622 it was taken by Tilly, after which it during the Thirty Years' War it was alternately in the hands of the imperial and the Hessian forces. In 1666 it came into the possession of Brandenburg. In 1761 and 1762 it was bombarded by the French, and in 1763 its fortifications were dismantled.

HAMMARSKÖLD, LORENZO (1785-1837), Swedish author, was born at Tuna, near Wimmerby, on the 7th of April 1785. He became a student at Uppsala in 1801, but failed to take his degree in 1806. He therefore accepted a humble post at the royal library at Stockholm, with which institution he remained connected for many years. In 1804 he published an article on Tieck and Novalis, which attracted much attention, and was the means of founding the "Phosphoric School," as it was called, of poetry in Sweden. Hammaršköld became the friend of Afterson and antagonist of Wallmark, and in due time, by the bitterness of his tone, brought down on himself the seathing anger of Tegnér. In 1806 he published *Translators and Imitations of Poets, Old and New*, in the preface of which he denounced the classic Swedish writers with much force and wit, commending Goethe and Tieck to the young poets of the day. In 1808 appeared his charming *Critique of Schiller*, and in 1810 a volume of essays of a polemical kind. In 1813 Hammaršköld published a collection of his poems, and in 1815 had to endure the ridicule of Tegnér in his brilliant satire of *Hammaršköld*. In 1818 appeared the first part of Hammaršköld's chief contribution to literature, his famous *Svenska Färdeteken*, a history of polite letters in Sweden, a book that was revived and republished after his death by Söndén, in 1833. He is chiefly remembered as a critic, his lyrics and his juvenile tragedy of *Prince Gustaf*, 1812, are of little value.

HAMME, a town of Belgium, in the province of East Flanders, and the arrondissement of Tournai or Dendermonde, is situated on the right bank of the Durme, near its junction with the Scheldt, and 18 miles E.N.E. of Ghent. It contains grain and oil-mills, manufactures of lace, ribbons, linen, starch, ropes, and cordage, and carries on trade in flax. Population (1876), 10,778.

HAMMER. This well-known tool stands quite without rival for producing the numberless effects which are due to the remarkable force of "impact." Of all the array of tools in use in the industrial arts it is undoubtedly one that could least be dispensed with, and so it must have been from the very earliest days of handicraft. A hammer of some rude kind must have been as essential to the aping of an arrow-head out of a flint, as is its modern representative to the forging of a bayonet out of a bar of steel.

Hammers to be used by hand are made of an endless variety of shapes, and of weights varying from a small taction of an ounce to 23 or 30 lb. Of the various types in use the differences are mainly due to the special requirements of the particular trades for which they are tended, but partly also to individual fancy. A few samples are given in fig. 1—*a* being the ordinary carpenter's hammer with a cross pane, *b* a claw hammer, *c* an engineer's, and *d* a shoemaker's hammer, which last has parently retained its form for many generations. The one may also be said of the two others in the woodcut,

FIG. 1.—Varieties of Hand Hammer.

high are good examples of the roughness of the instruments with which results of almost incredible delicacy can be produced. Of these *e* is a favourite hammer used in the workshops of a London firm of goldbeaters, with which, together with others not less rude in appearance, gold is hammered out into leaves of such exceeding thinness that 10,000 are required to make up the thickness of an inch. Extraordinarily ill-shaped as *f*, the file-cutter's hammer, looks, yet with this and a simple chisel the teeth of files are cut by hand with a precision with which no machinery as yet has been able to compete, at least in England.

Hand-hammers and sledge-hammers being rigidly limited to weight by the trifling power which one man—or at most two men—can bring to bear upon them, it long ago came obviously desirable to obtain the force of impact from some more powerful source than human muscles, so that the weight of hammer heads might be largely increased and their blows made proportionately more effective. The first step taken in this direction seems to have been the introduction of the "Hercules," a ponderous mass of iron attached to a vertical guide rod, which was lifted initially by a gang of men with ropes, but afterwards by steam power, and allowed to fall by its own weight. This is a fairly efficient tool for forging large anchors and for similar purposes, the strength of the blow and the point at which it was delivered being easily regulated. But as the demand for wrought iron increased, the necessity for more rapid as well as more powerful hammers to aid in its manu-

facture increased also. The lift or helve hammer (fig. 2) and the tilt hammer (fig. 3) thus came into use, and under these forms hammers may be said to have ranked for

FIG. 2.—Lift Hammer.

the first time as true machine tools. Each of these consists of a heavy head attached to a beam mounted on gudgeons, which is lifted at regular intervals by suitable cams or pins

FIG. 3.—Tilt Hammer.

carried by a revolving shaft driven by steam or other power, their chief points of difference being the relative position of the gudgeons and the portion of the beam at which the

FIG. 4.—Steam Hammer.

power is applied, as shown in the diagrams. Heavy blows are thus obtained with the one, and lighter but much more rapid blows with the other, both, however, invariable in their intensity, the lift being always to one fixed height.

In the steam hammer (fig. 1), which was first patented by Nasmyth in the year 1843, this objection is completely obviated. By the simple device of attaching the hammer head to the lower end of the rod of a piston working in an inverted steam cylinder, he produced a machine capable of being made to deliver its blows with a force to which no limit has yet been found, and yet so perfectly under control as to be able to crack a hazel nut without injuring the kernel. To the introduction of this invaluable tool is due more than to any other single cause the power which we now possess of producing the forgings in iron and steel which are demanded by the arts of modern times, and in one or other of its many forms it is now to be met with in every workshop in which heavy work is carried on. Many modifications of the Nasmyth steam hammer have been introduced. In one of these steam presses has been applied above the piston to intensify the blow, it being only used in the original form for lifting the "top" and piston and for regulating their descent. In another the piston and piston rod have been attached to the framing, and the cylinder made movable, its weight being thus added to that of the hammer.

Duplex hammers differ materially from the ordinary steam hammer, inasmuch as no anvil is necessary,—two hammer heads, of equal weight (and for some purposes they weigh only a few pounds, for others as much as 30 tons) being made to deliver horizontal blows of equal force simultaneously on opposite sides of the forging, which thus receive perfectly equal treatment. The importance of this may be gathered from the fact that every increase in the weight of the vertical steam hammer necessitates a very much larger increase in the weight and solidity of the anvil which is necessary to stand the requisite mortar for resisting the blow. For instance, the anvil of a 40-ton hammer now in use at Woolwich Aisnal weighs upwards of 100 tons, and has nearly 500 tons of iron in its foundation, whereas the anvil of an 80-ton hammer of which a full-sized model was amongst the most striking objects at the Paris Exhibition of 1878, is of no less than 720 tons weight.

The recent growth of steam hammers to the enormous size just mentioned is due chiefly to the large dimensions, independently of the mere weight, of the forgings, which have now to be made for heavy ordnance and for other purposes. As long as the thickness of a forging is moderate, the reaction of the anvil acting upon its under side has an effect not greatly inferior to that of the hammer on the upper side. But with every increase in thickness some of this reaction is lost and the effect of the blow is more and more confined to the outer portions of the mass, which thus receive more than their share of treatment at the expense of the central portions. On this account the difficulty of obtaining thick forgings thoroughly sound throughout their substance is very great, and it seems as if we had now reached the limit beyond which the hammer cannot be advantageously applied for their production. It has been found indeed in the case of large shafts that dispensing altogether with the central portion, thus making them tubular instead of solid, is accompanied by an increase in their strength, owing to the possibility of thus forging the metal uniformly throughout. But a much more widely applicable remedy, and one which will doubtless come into general use for heavy work, is the substitution of hydraulic or other pressure for the force of impact, a system which has lately been employed by Sir Joseph Whitworth with wonderfully good results. The reason of the superiority of its effect seems to be mainly this, that a certain amount of time is essential for completing the "flow" of the metal which it is the object of forging to induce. Under continuous pressure this flow can take place uniformly

throughout the mass, whereas the instantaneous blow of the hammer, though it acts violently on the surface particles, and to a decreasing extent on the adjacent ones, is entirely expended before the action has had time to reach those at the centre, so that unequal density and consequent weakness is the result. For massive forgings therefore the old saying can be no longer accepted that "there is no machine like a hammer." (C P B S.)

HAMMERFEST, the most northern town in Europe, is situated in the department of Hammerfest in the province of Finnmark, on the western side of the island of Kvalø (i.e., "Whale Island"), which lies off the north-western coast of Norway. Its latitude is 70° 39' 18", and the sea stays for two months above its horizon. Though a small place of about 2100 inhabitants, it is the seat of a considerable trade, in which not only Norwegian and Danish but English, German, and particularly Russian vessels are engaged. About thirty small ships are sent out from Hammerfest every spring to Spitzbergen to take part in the fisheries and walrus hunting. Tinned oil from the liver of the *Squalius macrocephalus* and cod liver oil are manufactured in the town. The exports, among which salted fish occupies the principal place, amounted in 1876 to the value of 1,629,800 crowns (£80,528), and the imports, chiefly salt and coal, to 721,700 (£40,094). On the Fuglesnes or Dud's Cape, which protects the harbour on the north, there stands a lighthouse with an elevation of 100 feet, and a station, stating that Hammerfest was one of the stations of the expedition for the measurement of the arc of the meridian. Nor is this its only association with science, for it was one of the spots chosen by Captain Sabine for his series of pendulum experiments. The accent of the Tyvon or Dubsberg in the neighbourhood is usually underlined by travellers.

HAMMER-HEAD See SHARK

HAMMER-PURGSTALL, JOSEPH VON (1774-1856), was born at Gatz in 1774, and after some training in the Oriental academy of Vienna entered the Austrian diplomatic service. He was the son of Joseph Johann von Hammer, and it was not till 1836, when he had inherited the estates of the comess of Purgstall (in Styria), that he received the title Baron von Hammer-Purgstall, by which he is generally known. His youth and early manhood were passed in the Levant, where he bent all his energies to the task of improving his acquaintance with Oriental literature, in which as early as 1796 he proved his interest by the translation of a Turkish poem. He did not again come forward as an author till 1801, when his *Encyclopædia of Oriental Learning* appeared, a work whose ambitious character was so diffidently felt by its author that he feared to put his name to it. From that time there was little pause in his literary productiveness. For fifty years he wrote incessantly on the most diverse subjects, and his works were composed in most of the languages of Europe. He published numerous texts and translations of Arabic, Persian, and Turkish authors, compiled histories of Persian poetry, Turkish poetry, and Arabic literature, brought the poems of Hafiz, Mutezib, Baki, and Ibn-el-Faridi within the reach of European readers, published travels in Turkey and Austria, wrote the history of the Tatar races, the Krim Khans, the Golden Horde, the Russians, and the Ottoman Turks, formed a biographical gallery of Eastern celebrities, put forth theories about every possible subject in the wide range of Oriental learning, discussing the *Arabian Nights*, Arab music, Mahometan theology, Egyptian papyri, gnostic ciphers, Arabic grammar, Eastern antiquities, the sect of the Assassins, the sieges of Vienna, the Knights Templars, and Spenser's sonnets, which he translated into German. Von Hammer did for Germany the same work that Sir William

Jones did for England. He showed that Oriental subjects were not to be studied merely so far as they were connected with biblical theology, but were a worthy object of research for their own sake. For more than fifty years he persisted in introducing Eastern authors and Eastern topics to the general reader, and there was a time when no Orientalist was more widely known and admired. As Jules Mohl said—"C'était le doyen de la littérature orientale, le premier associé que la Société (Asiatique de Paris) ait tenu à l'honneur d'insérer sur sa liste, et le plus zélé, le plus fertile, et le plus célèbre des hommes qui se sont vus, de notre temps, à la culture des lettres orientales."

It was natural that a scholar who traversed so large a field and wrote so rapidly should lay himself open to the criticism of specialists, and no man was more severely handled by his critics than Von Hammer, to whom Dies, for example (in *Unguy und Betuy*, 1815), devoted nearly 600 pages of heavy abuse. Von Hammer was undoubtedly inaccurate and superficial at times, he attempted more than he could possibly achieve with thoroughness, and was in the habit of giving his own whimsical view of matters about which he knew next to nothing, and he used to offend his critics as much by his Oriental florid style and want of method as by the occasional inaccuracy of his facts and the inconsequence of his deductions. But in spite of his faults he did more for Oriental studies than most of his critics put together.

When he was seventy-six years of age he planned a second edition of his *Encyclopædie of Oriental Learning*, and designed a "preliminary" series of twelve volumes which should clear the ground by expounding the history of Arabic literature, and for the last seven years of his life he regularly put forth his annual volume. Jules Mohl, going to see him, found the old man hard at work, helped by no colleague, and disclaiming the aid of an amanuensis. His early travels in the Levant, and then his busy life at Vienna, where he held the post of court-interpreter, saved him from the crushing influence of solitary study, and to the last he maintained his singular buoyancy of mind. "C'était un homme généreux, franc jusqu'à l'impudence, hardi, bouillonnant d'esprit, amiable jusqu'à la coquetterie, dont d'une fécondité de sa vieillesse, abondait dans les grandes et les petites choses, et d'une vivacité inextinguible—vivacité qui fut la source de sa bonne et de sa mauvaise fortune." So Mohl pictured him in his address to the Société Asiatique in 1857, when he recorded the death of Von Hammer on November 23, 1856, at the age of eighty-two, a hard worker to the last, like his younger but greater English contemporary Lane, with whom he came into collision in a friendly way on the subject of the origin of *The Thousand and One Nights*.

Von Hammer's principal works are his *Geschichte der orientalischen Literatur*, 10 vols., 1807 (2d ed., 1824-8), translated into French (1816 and 1840), *Geschichte der orientalischen Dichtkunst*, 4 vols., 1806, *Literatur-Geschichte des Araber* (unpublished), 7 vols., 1800-8, *Les Origines Russes*, 1821, *Geschichte der Goldenen Horde*, 1810, *Geschichte des Reichs*, 1842, *Geschichte des Chores*, 1810, 1866, *Geschichte des Asien*, 1818, *Constitutionelles und des Begeben*, 1822, *Ensayi topographique* (Uebersicht des Wissenschaften des Orients), 1804, *Uebersicht und Geschichte der Arabischen*, Arab. und Germ., 1820, *Im Wahrsayn*, *History of the Mongols*, Arab. und Germ., 1806, *El Wassaf*, Pers. und Germ., 1866, *Reich Schirvan's*, *Bewegungen des Schirvanen*, Pers. und Germ., 1838, *El Zem el-hakim*, *Goldene Zeit*, Arab. und Germ., 1856, *El Ghazal*, *Unguy et Idem*, Arab. und Germ., 1858, *El Harem*, *Das arab. Mohr Lied*, Arab. und Germ., 1854. Translations of—*El-Mutanabbi's Poems*, *El-Rumi's Account of his Embassy*, 1809, *Contes recueillis des 1001 Nuits*, 1828. Besides these, and smaller works, Von Hammer contributed numerous essays and notices to the *Zeitungswissen des Orients*, which he edited, to the *Journal Asiatique*, and to many other learned journals, above all to the *Transactions der Akademie der Wissenschaften* at Vienna, of which he was mainly the founder, and he translated

Erley's *Asiatick Travels in Europe*, for the English Oriental Translation Fund. For a full list of his works, which amount in all to nearly 100 volumes, see *Comptes Rendus* of the Acad. des Ins. et des Belles Lettres, 1867.

HAMMERSMITH, a town and parish in the county of Middlesex, situated on the north bank of the Thames, 3½ miles S.W. of Hyde Park corner, and now connected with London by continuous lines of streets. The bridge across the Thames at Hammersmith, completed in 1827 at a cost of £80,000, was the earliest suspension bridge erected near London. Formerly Hammersmith was celebrated for its nurseries and market gardens, but these have almost entirely given place to buildings. In the neighbourhood there are a number of fine residences. The principal public buildings are the parish church of St. Paul, consecrated in 1631 and restored in 1864, containing a number of interesting monuments, the Laytner schools, founded by Edward Laytner in 1624, the Godolphin school founded in the 16th century, and rebuilt as a grammar school in 1862, with accommodation for 200 boys, the Roman Catholic theological institute, founded originally as a school for ladies in 1669, the convent of the Good Shepherd, with an asylum for penitent women, the convent of Little Daughters of Nazareth, the Roman Catholic reformatory, the town-hall, the office of the board of works, and the West London hospital. In the district there are distilleries, lead-mills, oil mills, coach factories, boat-building yards, and the works of the West Middlesex Water Company. The population of the parish in 1861 was 24,519, and in 1871 42,691. Hammersmith falls within the limits of the metropolitan district, and forms part of the parliamentary borough of Chelsea.

HAMMOND, HENRY (1605-1660), a learned royalist divine of the Church of England, was born at Chertsey in Surrey, August 18, 1605. He was educated at Eton, whence in his fourteenth year he passed to Magdalen College, Oxford, becoming demy or scholar in 1619, and fellow in 1625. After graduating in arts he turned his attention to divinity, in 1629 he entered holy orders, and in 1631 became bachelor of divinity. Two years afterwards, in preaching before the court, he won the approval of the earl of Leicester, who in the same year presented him to the living of Fenchurch in Kent. Hammond received his doctor's degree in 1639, and in 1643 was promoted to the dignity of archdeacon of Chichester. He was a member of the convocation of 1640, and also, but nominally only, of the Westminster Assembly of divines, which began its sittings in 1643. In the latter year Dr. Hammond was concerned in the unsuccessful rising at Tunbridge in favour of King Charles I., and was obliged to flee in disguise to Oxford, then the royal headquarters. There he spent much of his time in writing, though he accompanied the king's commissioners to London, and afterwards to the ineffectual convention at Uxbridge in 1645, where he disputed with the Presbyterians. In his absence he was appointed canon of Christ Church, the public center of the university. These dignities he relinquished for a time in order to attend the king as chaplain during his captivity in the hands of the parliament. When Charles was deprived of all his loyal attendants at Christmas 1647, Hammond returned to Oxford and was made sub-dean of Christ Church, only, however, to be removed from all his offices in 1648 by the parliamentary visitors, who imprisoned him for ten weeks. Afterwards he was permitted, though still under quasi-confinement, to retire to the house of St. Philip Watwick at Clapham in Bedfordshire. In 1650, having regained his full liberty, Hammond betook himself to the friendly mansion of Sir John Pakington, at Westwood, in Worcestershire, where he died on April 25, 1660, just on the eve of his preferment to the see of Worcester.

Independently of his works, Hammond possessed qualities entitling him to be remembered long after his names are forgotten. He was an excellent preacher. Charles I pronounced him the most natural orator he had ever heard. His range of reading was extensive. A diligent scholar and a copious writer, he left no time for idleness, which he regarded as the heaviest burden and most dangerous temptation of man.

His writings, published in 4 vols fol. 1677-84, consist for the most part of controversial sermons and tracts. The best of them are his *Practical Catechism*, first published in 1647, his *Paraphrase and Annotations on the New Testament*, and an incomplete work of a similar nature on the Old Testament. His *Life*, written by Bishop Hall, and prefixed to the collected *Works*, has been republished in vol. iv of Woodworth's *Didactical Biography*. See also Lloyd's *Memories*, 1668, and *Life of Henry Hammond*, by the Rev G G Pury.

HAMON, JEAN LOUIS (1821-1874), one of the best known of French painters under the second empire, was born at Plouha on 3th May 1821. At an early age he was destined to the priesthood, and placed under the care of the brothers Lameznais, but his strong desire to become a painter finally triumphed over family opposition, and in 1840 he courageously left Plouha for Paris,—his sole resources being a pension of five hundred francs, granted him for one year only by the municipality of his native town. At Paris Hamon received valuable counsel and encouragement from Delacroix and Gleyre, and in 1848 he made his appearance at the Salon with *Le tombeau du Christ* (*Musée de Mantesville*), and a decorative work, *Deans de Forte*. The works which he exhibited in 1849—*Une Affiche Romaine*, *L'Égalité au Séculi*, and *Percequet jasant avec deux jeunes Filles*—obtained no marked success. Hamon was therefore content to accept a place in the manufactory of Sévres, but an enamelled casket by his hand having attracted notice at the London International Exhibition of 1851, he received a medal, and, rewarded by success, left his post to try his chances again at the Salon of 1852. *La Comédie Humaine*, which he then exhibited, turned the scale of his fortune, and *Mon sœur n'y est pas* (purchased by the emperor) obtained for its author a third class medal in 1853. At the Paris International Exhibition of 1855, when Hamon exhibited the casket of 1851, together with several vases and pictures of which *L'Amour et son Trompant*, *Ce n'est pas moi*, and *Une Gaiardeuse d'Enfants* were the chief, he received a medal of the second class, and the ribbon of the legion of honour. In the following year he was absent in the East, but in 1857 he reappeared with *Boutique à quatre Sous*, *Peppillon enchaîné*, *Cantharide oculte*, *Dévidentes*, &c., in all ten pictures. *L'Amour en vaine* was also exhibited. The year of 1859, and *Yierge du Lesbois*, *Tutelle*, *La Volière*, *L'Escompteur*, and *La Sour naine* were all seen in 1861. Hamon now spent some time in Italy, chiefly at Capri, whence in 1864 he sent to Paris *L'Aurore* and *Un Jou de Fiançailles*. The influence of Italy was also evident in *Les Muses à Pompéi*, his sole contribution to the Salon of 1866, a work which enjoyed great popularity and was re-exhibited at the International Exhibition of 1867, together with *La Promenade*, and six other pictures of previous years. His last work, *Le triste Rivage*, appeared at the Salon of 1873. It was painted at St Raphael, where Hamon had finally settled in a little house on the shores of the Mediterranean, close by Alphonses Karl's famous garden. In this house he died on the 29th of May 1874, and the contents of his studio and portfolios were dispersed at an obscure sale—thinly attended—for an almost nominal sum. Hamon had made his own a quiet place amongst those workers who since the days of Vien and David have been trying to bring home to us something of the pictorial aspect of classic time. He had neither the power nor the learning which might have enabled him to

give to that aspect any very real shape, nor was the side of human life with which he was most concerned weighty or important. He especially loved the postures of children and their little ways,—now comic, now cunning, but always naive, and always full of charms. Dressed in classic fashion they play on the canvas of Hamon, with endless fanciful alterations, the same nursery comedies of which *Ma sœur n'y est pas* is one of the best examples. The painter's very mannerisms, his pale colour, and the lazy atmosphere which pervades his often rather empty field, enhance the graceful unreality of these little creatures, who are not quite classic lovers nor yet altogether human babies.

HAMPDEN, JOHN (1594-1643), the eldest son of William Hampden of Great Hampden in Buckinghamshire, by Elizabeth, second daughter of Sir Henry Cromwell, and aunt of Oliver, the future Protector, was born in 1594. By his father's death, when he was but a child, he became the owner of a good estate, and a ward of the crown. He was educated at the grammar school at Thame, and in 1609 he became a commoner of Magdalen College at Oxford. In 1613 he was admitted a student of the Inner Temple, and in 1619 he married Elizabeth Symeon. He first sat in parliament for the borough of Grampound in 1621. From that time he was a member of every succeeding parliament till he died.

To the biographer who does not wish to become an historian under the pretence of narrating the incidents of his hero's life, Hampden's career must appear to give little scope for narrative. The letters which he left behind him are few. His speeches are scarcely more numerous and are extremely brief. In the early days of his parliamentary career he was content to be overshadowed by Eliot, as in its later days he was content to be overshadowed by Pym, and to be commanded by Essex. Yet it is Hampden, and not Eliot or Pym, who lives in the popular imagination as the central figure of the English revolution in its earlier stages. It is Hampden whose statue rather than that of Eliot or Pym has been selected to take its place in St Stephen's Hall as the noblest type of the parliamentary opposition, as Falkland's has been selected as the noblest type of parliamentary royalism.

Something of Hampden's fame no doubt is owing to the position which he took up as the opponent of ship-money. But it is hardly possible that even resistance to ship-money would have so distinguished him but for the mingled massiveness and modesty of his character, his dislike of all pretences in himself or others, his brave contempt of danger, and his charitable readiness to shield others as far as possible from the evil consequences of their actions. Nor was he wanting in that skill which enabled him to influence men towards the ends at which he aimed, and which was spoken of as subtlety by those who disliked his ends.

During the last two parliaments of James and the first three parliaments of Charles, Hampden did not, so far as we know, open his lips in public debate, but he was increasingly employed in committee work, for which he seems to have had a special aptitude. In 1626 he took an active part in the preparation of the charges against Buckingham. In January 1627 he was bound over to answer at the council board for his refusal to pay the forced loan. Later in the year he was committed to the gate-house, and then sent into confinement in Hamphire, from which he was liberated just before the meeting of the third parliament of the reign, in which he once more rendered useful but unobtrusive assistance to his leaders.

When the breach came in 1629 Hampden is found in epistolary correspondence with the imprisoned Eliot, dissenting with him the prospects of the Massachusetts colony, or rendering hospitality and giving counsel to the patriots sons now that they were deprived of a father's personal care.

It was not till 1637, however, that his resistance to the payment of ship-money gained for his name the fame which it has never since lost. Even out of the twelve judges aided against him, but the connexion between the rights of property and the parliamentary system was firmly established in the popular mind.

In the Short Parliament of 1640 Hampden stood forth amongst the leaders. During the eventful months which followed, when Stafford was striving in vain to force England, in spite of its visible reluctance, to support the king in his Scottish war, rumour has much to tell of Hampden's activity in rousing opposition. It is likely enough that the rumour is in the main true, but we are not possessed of any satisfactory evidence on the subject.

In the Long Parliament, though Hampden was by no means a frequent speaker, it is possible to trace his course with sufficient distinctness. Unwearied in attendance upon committees, he was in all things ready to second Pym, whom he plainly regarded as his leader. In the earlier proceedings of the Commons there was practically unanimity in the House, though a difference afterwards arose as to the form in which the attack upon Stafford should be conducted. All were agreed in desiring that the constitution should rest upon a combination between the king and the two Houses, and that legal questions in which the king was concerned should be decided only by the judges or the ordinary courts.

There was another point on which there was no agreement. A large minority wished to retain Episcopacy, and to keep the Common Prayer Book unaltered, whilst the majority were at least willing to consider the question of abolishing the one and modifying the other. On this subject the parties which ultimately divided the House and the country itself were fully formed as early as February 8, 1641. The details of the contest between Episcopacy and Presbyterianism will be more fully told in connexion with the life of Pym. It is enough to say that Hampden fully shared in the counsels of the opponents of Episcopacy. It is not that he was a theological Presbyterian, but the bishops had been in his days so fully engaged in the imposition of obnoxious ceremonies that it was difficult if not impossible to dissociate them from the cause in which they were embarked. Closely connected with Hampden's distrust of the bishops was his distrust of monarchy as it then existed. The dispute about the church therefore soon attained the form of an attack upon monarchy, and, when the majority of the House of Lords arrayed itself on the side of Episcopacy and the Prayer Book, of an attack upon the House of Lords as well.

No serious importance therefore can be attached to the offers of advancement made from time to time to Hampden and his friends. Charles would gladly have given them office if they had been ready to desert their principles. Every day Hampden's conviction grew stronger that Charles would never abandon the position which he had taken up. He was therefore a warm supporter of the Grand Remonstrance, and was chosen out to be one of the five impeached members whose attempted arrest brought at last the opposing parties into open collision. In the angry scene which arose on the proposal to print the Grand Remonstrance it was Hampden's personal intervention which prevented an actual conflict, and it was after the impeachment had been attempted that Hampden laid down the two conditions under which resistance to the king became the duty of a good subject. Those conditions were an attack upon religion, and an attack upon the fundamental laws. There can be no doubt that Hampden fully believed that both those conditions were fulfilled at the opening of 1642.

When the civil war began Hampden levied a regiment

of Buckinghamshire men for the parliamentary cause. In the earlier operations of the war, and in the undecided fight of Edgehill, he bore himself gallantly and well. But it is not on his skill as a regimental officer that Hampden's fame rests. In war as in peace his distinction lay in his power of disentangling the essential part from the non-essential. In the previous constitutional struggle he had seen that the one thing necessary was to establish the supremacy of the House of Commons. In the military struggle which followed he saw, as Cromwell saw afterwards, that the one thing necessary was to beat the enemy. He protested at once against Essex's hesitations and compromises. In the formation of the confederacy of the six associated counties, which was to supply a basis for Cromwell's operations, he took an active part. His influence was felt alike in parliament and in the field. But he was not in supreme command, and he had none of that impatience which often leads able men to fail in the execution of orders of which they disapprove. His pious life was a sacrifice to his unselfish devotion to the call of discipline and duty. On June 18, 1643, when he was holding out on Chalgrove Field against the superior numbers of Rupert till reinforcements arrived, he received two carbine balls in the shoulder. Leaving the field he reached Thame, and after nearly six days he died on the 24th praying for his country and his king.

HAMPDEN, BORN DICKSON (1793-1898), bishop of Hereford, was born at Barbados, where his father was colonel of the local militia, in 1793, and after receiving a private school education under Dr Rowlandson, vicar of Warmistoe, Wiltshire, entered as a commoner at Oriel College, Oxford, in 1810. Having taken his B.A. degree with first-class honours in both the classical and mathematical schools in 1813, he in the following year obtained the chancellor's prize for a Latin essay "On the Office of the Ephors at Sparta," and shortly afterwards he was elected to a fellowship in his college, Keble, Newman, and Arnold being among the number of his contemporaries. Having left the university in 1816 he held successively the curacies of Newton, Faringdon, and Hookney, and in 1827 he published *An Essay on the Philosophical Evidence of Christianity*, followed by a volume of *Parochial Sermons illustrating of the importance of the Revelation of God in Jesus Christ* (1828). In 1828 he returned to Oxford as tutor of Oriel, and after having twice acted as public examiner in classics, he was selected to preach the Bampton lectures in 1832, when he chose for his subject *The Scholastic Philosophy considered in its Relation to Christian Theology* (1833, 8d ed 1848). Notwithstanding a charge of Arrianism now brought against him by the Tractarian party, he in 1834 obtained the principality of St Mary's Hall, and in 1835 the chair of moral philosophy, nor did a university statute of censure against him on the ground of the supposed heterodoxy of the Bampton lectures avail to check his promotion to the regius professorship of divinity in 1836. These resulted a widespread and violent though ephemeral controversy, after the subsidence of which he published a *Lectures on Tradition*, which has passed through several editions, and a volume on *The Thirty-nine Articles of the Church of England*. His nomination by Lord John Russell to the vacant see of Hereford in December 1847 was again the signal for a violent and organized opposition, and his consecration in March 1848 took place in spite of a remonstrance by many of the bishops and the resistance of Dr Merewether, the dean of Hereford, who went so far as to vote against the election when the *comité d'Etat* reached the cathedral. As bishop of Hereford Dr Hampden made no change in his long-formed habits of studious seclusion, and his episcopate was not characterized in a special degree by any form of churchly

activity or zeal. Among the more important of his later literary performances were the articles on Aristotle, Plato, and Seneca, contributed to the eighth edition of the *Encyclopædia Britannica*, and afterwards republished with additions under the title of *The Pathos of the Greek Philosophy* (Edinburgh, 1809). In 1806 he had a paralytic seizure which unhinged him for several mental exertion, and he died at London on the 23d of April 1808.

PLATE VII HAMPSHIRE, (HANTS.), or SOUTH-WYRE (most anciently *Hamtanascire*, in Domesday book *Hamtaneshire*, and in the documents of the Middle Ages *Suthhamtescire*, *Suthhamtonscire*, and *Sudenhamptonscire*), a maritime county in the south of England, is situated between 50° 34' and 51° 23' N lat and 0° 49' and 1° 51' W long, and is bounded on the N by Berkshire, on the E by the county of Surrey and Sussex, on the S by the English Channel, and on the W by Wiltshire and Dorsetshire. It is of an irregular quadrilateral form, and its greatest breadth from north to south, not including the Isle of Wight, is 46 miles, and its greatest breadth from east to west 41 miles. The total area comprises 1,032,105 imperial acres (manorial portion 938,764 acres, Isle of Wight 93,341), or nearly 1613 square miles. Hampshire in its general aspect presents a beautiful variety of gently rising hills and fruitful valleys, adorned with numerous mansions and pleasant villages, and interspersed with extensive woodland. Two ranges of low chalk hills, known as the North and South Downs, enter the county from Surrey and Sussex respectively, and traverse it in a north-easterly direction into Wiltshire and Berkshire, forming in the north-western corner of the county several picturesque eminences, from which some fine views are obtained. The highest of these summits is Sittouan Hill, Highclere, 940 feet. The northern and north-eastern portion of the county, comprising more than 100,000 acres, is in the basin of the Thames, a large portion of the southern district is in the Southampton or Isle of Wight basin, and a portion to the west is in the basin of Wilts and Dorset. The south-western corner from Southampton Water is almost wholly occupied by the New Forest. The coast on the whole is low and irregular. The most easterly part forms a large bay containing Hayling Island and Portsea Island, which divide it into Chichester harbour, Langston harbour, and Portsmouth harbour. From the south-western extremity of Portsmouth harbour it runs about 18 miles inland in a north-west direction, and forms Southampton Water, which has a western shore about 10 miles in length, and an average breadth of nearly 2 miles at high water. From Southampton Water its line is continued irregularly in a south-western direction — for nearly one half of the extent forming the Isle of Wight, and in its western half forming Christchurch Bay and part of Poole Bay.

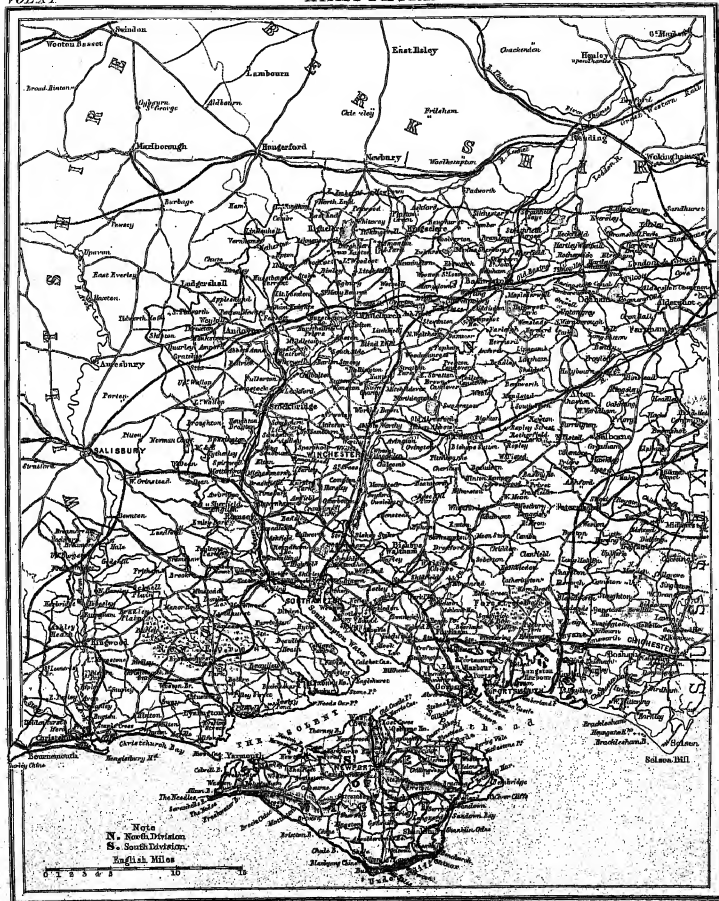

Rivers and Canals.—The principal rivers are the Avon, the Boldre, the Exe, the Test with its tributary the Anton, the Itchen, and the Hamble. The Avon in the south-west of the county has its source in Wiltshire, and passing Fordingbridge and Ringwood empties itself into Christ Church Bay, where it is joined by the Stour, which issuing in Dorset crosses the south-west corner of Hampshire. The Boldre takes its rise in the New Forest, and after collecting the water of several brooks falls into Lymington creek. The Exe runs the eastern extremity of the New Forest falls into the Solent at Beaulieu. The Test rises near Overton, and after its junction with the Anton at Fullerton passes Stockbridge and Romsey, and forms the head of Southampton Water. The Itchen rises near Alresford, and flowing by Kingsworthy, Winchester, and Twyford falls into the Southampton Water to the north of Southampton. The Hamble rises near Bishop's Waltham, and after a course of about 10 miles falls into the South-

ampton Water. The Wey, the Embourne, the Loddon, and the Blackwater have their rise in the north part of the county, but soon pass into Berkshire.

There is one canal, Basingstoke, begun in 1778 and completed in 1794 at a cost of £100,000. It is 87 miles in length and terminates in the river Wey, in Surrey, near its junction with the Thames. Andover canal, begun in 1789, is 5 miles filled up in 1858 and converted into a rail way, forming a junction with the London and Exeter at Andover.

Geology and Soil.—With the exception of the northern and north-eastern corner occupied by the basin of the Thames, another portion about 8 miles in length extending along the eastern side, and the New Forest in the south-west, with a small portion to the north of it, Hampshire is occupied by the Chalk formation which runs from Sussex and Surrey north-east into Wilts and Berks. This middle district has a length from north to south of about 52 miles and a breadth from east to west of between 20 and 30 miles. Its soil is in some places of considerable depth, and produces good crops of all kinds, but a great part of it is so thin as to be unfitted for the plough, and is used as sheep pasture. The basin of the Thames to the north of this district is principally strong brown and grey loam, with a considerable number of marishes. The eastern portion forming the Vale of Petersfield, and comprising only about 50,000 acres, rests on the Wealden formation under a grey sandy loam, provincially called "malny" land, lying on a soft sand rock. The southern portion, which includes the ancient Forest of Basing, Waltham Chase, and the New Forest, consists principally of light sandy and gravelly loams intermixed with clay and brick earth, resting chiefly on argillaceous and calcareous mail.

Agriculture.—According to the Agricultural Statistics for 1879, the total area of arable land was 706,937 imperial acres, of which 217,968 were under corn crops, 186,222 under grass, 131,818 under rotation grasses, 184,341 permanent pasture, and 22,967 fallow. The average under woods was 87,520. The principal grain crop is wheat, for which Hampshire enjoys a great celebrity. Its average has been gradually increasing, and in 1879 was 100,090. The average of barley and oats was 86,323, and 61,967 respectively. Barley is usually sown after turnips, and is more grown in the uplands than in the low levels. Beans and pease are only grown to a small extent, the average in 1879 being respectively 4683 and 10,002. On account of the number of sheep pastured on the uplands a large amount of turnips is grown, their average in 1879 being 31,472. Potatoes are not cultivated to any extent, and are necessary for home supplies, and had an average of only 6038. Rotation grasses are grown chiefly in the uplands, and their average is greater than in any other of the southern counties of England. Station is the grain most largely grown, as is best adapted to the soil, and the calcareous subsoil. In the lower levels no manure and scarcely any clover is grown, the hay being supplied from the rich water meadows, which are managed with great skill and attention, and give the best money return of any lands in the county. Where a rapid stream of water can be passed over them during the winter it seldom becomes frozen, and the grasses grow during the cold weather so as to be fit for pasture before any traces of vegetation appear in the surrounding fields. Hops are extensively grown in the eastern part of the county bordering on Surrey. Their average in 1879 was 8084. Fanning is generally conducted on the best modern principles, but owing to the nature of the soil there is perhaps no county in England in which the rotation observed is more diversified, and the processes and methods more varied. Most of the farms are large, and there is a considerable number of model farms. The waste land has been mostly brought under tillage, but a very large acreage of the ancient forests is still occupied by wood. New Forest has 60,000 acres under wood, in addition to which there are in the east Woolmer Forest (6940) and Alice Holt (2744), in the south east the Forest of Bere (11,000) and Waltham Chase (2000), and in the Isle of Wight Punkbury Forest (3000). The New Forest was originally founded by William the Conqueror in 1070 after the battle of Hastings, and the greater part of it belongs to the crown. The trees of the forest are principally beech and oak. The oaks, many of which are some hundred years old, do not grow to great height, but shoot strong crooked branches which give them a very picturesque appearance. Formerly they were chiefly used for the ships of the royal navy. Heads of small ponies similar to those of the Shetland and the Hebrides are still reared in the Forest. It also contains abundance of deer,

sustained by the final transference of the seat of government to London was partially compensated by the rise of the ports of Southampton and Portsmouth, which have been in important element in its prosperity down to the present time. The principal cities historical events of the shire are connected either with the two towns or with Winchester, or the Isle of Wight, the only exception of importance being the siege and capture of Basing House by the troops of Cromwell in 1645.

The principal monastic institutions in Hampshire, dissolved by Henry VIII., was the priory of St. Swithun, who was bishop of Winchester from 852 to 862, the monastery of Hyde, outside the walls of Winchester, founded by King Alfred, the nunnery of St. Mary's, Winchester, St. Bartholomew's College, Winchester, the nunnery of Wherwell, founded by Elfrida, the Augustinian priory of Southwick, founded by William of Wykeham, the Priorem stratusan abbey of Titchfield, founded in the time of Henry III., the Augustinian priory of Totton, which, Christchurch, founded according to some authorities by King Athelstan, the Augustinian priory of Bleanore, founded by Baldwin de Redvers, the nunnery of Romsey, founded by Edward the Elder about 910, the Augustinian priory of Mottisfont, endowed soon after the Conquest, but by whom is uncertain, the Cistercian abbey of Beaulieu, founded by King John about 1204, the Cistercian abbey of Netley, founded in the time of Henry III., the Augustinian priory of St. Dennis, near Southampton, founded by Henry I., the abbey of Quantock, of Wight, and the preceptory of Badlesley. The most important monastic remains are those at Winchester, the priory church at Christchurch in the Norman and Perpendicular style, the Norman church at Romsey, the remains of Netley Abbey, with a church in the Early English style, the ruins of Beaulieu Abbey, of which a gateway is in good preservation (the abbey's house has been converted into a private residence, and the great hall or refectory, in the ruin Early English style, is now a private parish church), the ruins of the priory of St. Dennis, and the Norman church at Portchester, near Portsmouth. Colnhampton church, near Exton, is the only Saxon church in Hampshire which is entirely of Saxon masonry is found in Headbourne Worthy church, which also contains an old house of the 15th century. The principal other old churches not mentioned under Winchester, Southampton, and other towns, are already mentioned in connection with monastic institutions in the Norman style, Chilcomb, Hamble, Kingsclere, and Littlebourne, in the Norman style, with Early English additions, Alton, Basing, Bishop's Sutton, Blokehampton, Clarendon, Hambledon, Milford, and Wootton Bassett, in the Early English style, Otherton, Gritely, Sopley, which is partly Perpendicular, and Thurstington, which contains a house to St. John Lane (died 1497), affording the earliest example of complete plate armour in England, and in the Fulmencliff, Basingstoke, Tordinglebridge, which is also partly Decorated, Titchfield, Silchester, and Wokingham.

The principal old castles are Calshot Castle, built in the time of Henry VIII., and used by the coast guard, Castleside Castle (see WOOTTON, ISLAND), Hurst Castle, near Southampton, where Charles I. was for a short time imprisoned, now transformed into a fortress, and Portchester Castle (see PORTCHESTER). The modern residences of the gentry are more numerous than in any other county. Among the eminent persons connected with Hampshire may be mentioned Young, author of the *Night Thoughts*, Watson, author of the *History of English Poetry*, Dibdin, Bishop Wykeham, Foxe, the traveler, and the poets, Hayway, Bamel, Gilbert White, John Keble, and Charles Dickens.

See the paper regarding the early history of South Britain by Dr. Quares in the *Archæological Journal*, and in the *Transactions of the Archaeological Institute*. *Hampshire's extended and interesting book* by Richard Warner, 1789, *Memoirs of Hampshire*, as 1086 (1802), and the same author's *Antiquarian and Topographical Sketches*, 1846, and *Notes and Remains relating to the Counties of Hants and W. Hants*, 1849. *St. Michael's and the Isle of Wight*, 2 vols., 1849. *J. Daines, Sketches of Hampshire*, 1810. *P. J. Martin, Geology of Hampshire*, 1871. *Michaelmas and the Isle of Wight*, 1871. Woodward's important *History of Hampshire*, 1870, and White's *History and Topography of Hampshire and the Isle of Wight*, 1870.

HAMPSTEAD, a suburb of London, is situated in the county of Middlesex, on the slope of Hampstead Hill, 4 miles N.W. of the city. The village is irregularly built, and the streets are narrow and tortuous, but it has preserved more than any other London suburb its sylvan appearance, and is still noted for its fine groves and avenues. From the side of the hill there issue chalybeate springs, whose virtue was first discovered in the 17th century, and which at the beginning of last century rivalled those of Tunbridge Wells and Epsom in popularity. Their reputation, however, gradually declined after the middle of the century, and now the

supply of mineral water has been greatly diminished by the cutting of deep drains and of railway tunnels. Hampstead Heath, an irregular sandy tract occupying the summit and northern slope of the hill, and extending to 240 acres, is most frequented by excursionists and picnic parties. The hill is the highest in the vicinity of the metropolis, being 443 feet above the level of the Thames, or 36 feet higher than the cross of St. Paul's. At one time the village was a favourite resort of poets and other men of letters, and among the more famous of its old taverns was the Flask Inn, now converted into a private residence, the meeting place of the Kit Cat club, of which the more celebrated members were Addison, Steele, Richardson, Marlowe, and Walpole. The parish church of St. John, consecrated in 1747 and enlarged in 1844, is a plain brick structure in the Italian style with a picturesque tower. The graveyard contains a number of monuments of eminent persons, including those of Sir James Mackintosh, Joanna Bailie, and Constable the artist. Near the village a large militia barracks was erected in 1863, and there are a number of charitable institutions, including a soldiers' daughters' home, a sailors' daughters' home, an orphan working school, and the North London Consumptive Hospital. The population of the parish in 1871 was 52,381.

HAMPTON, a village in the county of Middlesex, England, is situated on the north bank of the Thames, 12 miles WSW from Hyde Park Corner. The parish church erected in 1830, with a square tower at its western end, is without architectural merit, but the churchyard contains a number of interesting old monuments. Among the many fine residences in the vicinity is Garrick Villa, formerly, under the name of Hampton House, the residence of Garrick the famous actor. In the neighbourhood there are a number of large pumping works for supplying London with water. The free grammar school founded in 1559 was reopened in 1878 as a middle class school, for which the usual fees are charged. The population of the village in 1871 was 2307.

About a mile from Hampton village and close to the river stands Hampton Court Palace, one of the finest extant specimens of the Tudor style of architecture, and formerly a royal residence. It was originally erected by Cardinal Wolsey, who in 1515 received a lease of the old mansion and grounds for 99 years. As the splendour of the building seemed to awaken the cupidity of Henry VIII., Wolsey in 1526 thought it prudent to make him a present of it. It became Henry's favourite residence, and he made several additions to the building, including the great hall and chapel in the Gothic style. Of the original five quadrangles only two now remain, but a third was erected by Sir Christopher Wren for William III. The fine gardens, extending to 44 acres, were laid out at the desire of William III. in the Dutch style, with elevated terraces, long shady walks, and a labyrinth called the "Maze" which is the source of great amusement to visitors. Bushy Park, opposite the palace gardens, is open to the public, and contains a celebrated avenue of chestnut trees. The palace was sold by the parliament in 1641, but afterwards came into the hands of Cromwell, and it continued to be one of the principal residences of the English sovereigns until the time of George II. It was the birthplace of Edward VI., and the meeting place of the conference held in the reign of James I. to settle the dispute between the Presbyterians and the state clergy. It is now partly occupied by persons of rank in reduced circumstances, but its state apartments, picture gallery, and gardens are open to the public free of charge. The celebrated cartoons of Raphael which it formerly possessed have lately been removed to the South Kensington

Museum, but it still contains a valuable collection of pictures, including a number of fine specimens of the old masters, and a large collection of portraits of persons famous in English history.

HAMSTER (*Cricetus*), a genus of rodent mammals belonging to the *Muridae* or mice family, and characterized by the possession of large cheek pouches. The common hamster (*Cricetus vulgaris*) is somewhat larger and stouter than the Norway rat, but with a much shorter tail. Its fur, which varies somewhat in colour, is generally of a reddish-brown above and black beneath, with several white spots on the sides. It is found throughout the dry regions of central Europe and Asia, from the Rhine eastward to the river Obi and southward to Persia and the Caucasus. It is a burrowing animal, its subterranean dwelling consisting of several vaults, most of which are used as storehouses for the grain and seeds which the hamster lays up in autumn for consumption during winter and spring. In collecting this store it makes use of its cheek pouches, which are said to be large enough to contain a quartet of an English pint, while the hoard of a single individual will sometimes contain about two bushels of grain. It is thus specially obnoxious to the farmer, who loses no opportunity of destroying the creature and of ransacking its stores. Like many other rodents, the hamster is exceedingly prolific, the female producing several broods in the year, each consisting of over a dozen young, and these when not more than three weeks old are turned out of the parental burrow to form underground homes for themselves. The burrow of the young hamster is only about a foot in depth, while that of the adult descends 4 or 5 feet beneath the surface.

On the approach of winter the hamster retires to its subterranean abode, the various entrances to which it carefully closes, and there it remains until the advent of milder conditions, feeding for a while on its well-garnished store, but becoming torpid during the coldest period of winter. Although feeding chiefly on roots, fruits, and grain, it is also to some extent carnivorous, attacking and feeding upon small quadrupeds, lizards, and birds. It is exceedingly fierce and pugnacious, the males especially fighting with each other for possession of the females. The numbers of these destructive vermin are kept in check by their many natural enemies, the foxes, dogs, cats, and polecats, which feed upon them. The skin of the hamster is of some value, and its flesh is used as food. Its burrows are sought after in the countries where it abounds, both for capturing the animal and for riding its store.

HANAU, a town of Prussia, capital of a circle in the government district of Cassel, province of Hesse-Nassau, is situated at the confluence of the rivers Kinzig and Main, 12 miles E of Frankfurt. It consists of what is called an old and a new town. The streets of the former are narrow and irregular, but the latter, founded at the end of the 16th century by refugee Walloons and Netherlands, is built in the form of a pentagon with broad streets crossing at right angles, and possesses several fine squares, among which may be mentioned the market-place, adorned with handsome fountains at the four corners. The town is the seat of a circle court, a head tax-office, a chamber of commerce, and a branch of the imperial bank. Among the principal buildings are the ancient castle, formerly the residence of the counts of Hanau, the church of St John, dating from the 17th century, with a rather imposing tower, the old church of St Mary, formerly a collegiate church, and containing the tomb of the counts of Hanau, the church of the new town, built in the beginning of the 17th century, whose ground plan is in the form of two circles intersecting each other, the beautiful new Gothic church, the synagogue, the theatre, the barracks, the arsenal, the orphanage, the infirmary. Its educational establishments include a

gymnasium, a school of design, a real school, and a higher girls' school. There is a Wörrerian society of natural history and an historical society, both of which possess considerable libraries and collections connected with their respective branches of knowledge. Hanau is the birthplace of the brothers Grimm, and the house in which they were born is now adorned with a medallion. In the neighbourhood of the town are the electoral palace, with an extensive park and large orangeries, and the watering-place of Wilhelmsbad. Hanau is the principal commercial and manufacturing town in the province, and stands next to Cassel in point of population. Its staples are ornaments of various kinds, cigars, leather, paper, playing cards, silver and platinum wares, chocolate, soap, woollen cloth, hats, silk, gloves, stockings, ropes, and matches. It has also three large foundries and a number of breweries, and in the neighbourhood there are extensive powder-mills. It carries on a large trade in wood, wine, and corn, in addition to its articles of manufacture. The population of the town in 1875 was 22,369.

From the number of coins, and other antiquities found near Hanau it would appear that it owes its origin to Roman settlement. It was said to be the rank of a town in 1089, and in 1628 it was fortified by Count Philip, who rebuilt the castle. At the end of the 16th century its prosperity received considerable impulse from the accession of the Walloons and Netherlands. During the Thirty Years' War it was in 1631 taken by the Swedes, and in 1686 it was besieged by the imperial troops, but was relieved on the 18th June by Landgrave William V. of Cassel, on account of which the day is still commemorated by the inhabitants. Napoleon on his retreat from Leipzig defeated the Germans under Marshal Witt at Hanau, October 30, 1813, and on the following day the allies recaptured the town, when it was entered by the French. In 1499 Hanau became the capital of a province of the empire, which on the death of Count Ruland II was in 1461 partitioned between the Hanau-Münzenberg and Hanau-Lichtenberg lines, but was reunited to the latter in 1527. It had been extinct, but has recovered princely rank in 1866, but, as it also became extinct, Hanau-Münzenberg in 1786 was joined to Hesse-Cassel and Hanau-Lichtenberg to Hesse-Darmstadt. In 1785 the whole province was united to Hesse-Cassel, and in 1806 it became an independent principality. In 1813 it again came into the possession of Hesse-Cassel, and in 1866 it was joined to Prussia.

HANCOCK, JOHN (1737-1793), American revolutionary statesman, was born at Quincy, Massachusetts, January 12, 1737. Having taken his degree at Harvard university in 1754, he began a mercantile career, and on the death of an uncle in 1764 succeeded to a large fortune and a prosperous business. In 1768, two years after his election to the Massachusetts house of representatives by the city of Boston, his sloop "Liberty" was seized for contravention of the commercial laws, and in the riot which followed the royal customs commissioners barely escaped with their lives. After the "massacre" of Boston in 1770, Hancock inveighed with such spirit and bitterness against the troops and their officers, demanding their removal from the town, that he became obnoxious to the Government, and five years afterwards the attempt to seize his person led to the first revolutionary battle at Concord, Massachusetts. In 1774 Hancock was president of the provincial congress, and from 1775 to 1777 of the general congress at Philadelphia, where he was the first to sign the declaration of independence. Returning to Massachusetts he assisted in framing its constitution, and in 1780 was chosen first governor. He was annually elected to this dignity till 1785, and again from 1787 to 1793, sitting as an ordinary member of the legislature in the interval. He received the degree of LL.D. from Harvard university in 1792. He died at Quincy, 8th October 1793.

HANDEL, GEORGE FREDERICK (1685-1759), one of the greatest names in the history of music generally, is absolutely paramount in that of English music. His influence on the artistic development of England and his popularity, using that word in the most comprehensive sense, are

perhaps unequalled. He has entered into the private and the political life as well as into the art life of Englishmen, without him they cannot bury their dead or elect their legislators, and never has a composer been more essentially national than the German Handel has become in England. It may on the other hand be said that but for his sojourn in that country Handel would never have been what he was. It was under the influence of English poetry, and of English national and religious life, that his autistic conception broadened and gained the dignity and grandeur which we see in his oratorios, and which was wanting, and, seeing the style of art, could not but be wanting, in his Italian operas. The day of Handel's arrival in London, late in the autumn of 1710, was indeed an eventful day in the life of Handel as well as in the annals of English music, and the facts of his biography preceding that date may be summed up with comparative brevity. George Frederick Handel (in German the name is always Handel) was born at Halle in Saxony on February 23, 1685, the same year which gave birth to his great fellow composer Johann Sebastian Bach.¹ He was the son of George Handel, who according to the custom of the time combined the occupations of barber and surgeon, and subsequently rose to be valet-de-chambre to the elector of Saxony. His second wife, Dorothea Taub, was the daughter of a clergyman, and to her the great composer remained attached with all the ties of filial affection. His father was sixty-three years old when Handel was born, and the musical talent shown by the youth at a very early age found little encouragement from the stern old gentleman, who looked upon art with contempt, and destined his son for the law. Many are the anecdotes relating to the superstitious way in which the youth practised the forbidden art on a little spinet smuggled into his attic by the aid of a good-natured aunt, and fortunately of too feeble tone to be audible in the lower part of the house. At the age of eight the boy accompanied his father on a visit to Saxony, Weissenfels, and it was there that the proficiency acquired in the manner above described was tuned to excellent account, for, having made acquaintance with the court musicians, and being allowed to practise on the organ, he was on one occasion overheard by the duke himself, who immediately recognizing his talent spoke seriously to the father on his behalf. To such a remonstrance coming from such a quarter the valet-de-chambre had of course to submit, and henceforth Handel was allowed to practise his art, and after his return to Halle even received musical instruction from Zachau, one of the best organists of the town. It was under his somewhat mechanical but thorough tuition that Handel acquired his knowledge of counterpoint, he also soon became an excellent performer on the organ. His first attempts at composition date from an equally early period, and in his twelfth year he made his debut as a virtuoso at the court of Berlin with such success that the elector of Brandenburg, afterwards King Frederick I. of Prussia, offered to send him to Italy, a proposal declined by Handel's father for unknown reasons. In 1697 the latter died, and the young artist was henceforth thrown on his own resources. For some years he remained in Halle, where in 1702 he obtained a position as organist, but in the following year we find him at Hamburg, at that time one of the musical centres of Germany. There the only German opera worth the name had been founded by Reinhold Keiser, the author of innumerable operas and operettas, and was flourishing at the time under his direction. Handel entered the orchestra, and soon rose from his place among the second violins to the conductor's seat at the clavicembalo, which he occupied during Keiser's

¹ The date, 28d February 1684, given on his tombstone in Westminster Abbey is incorrect.

absence, necessitated by debt. It was at Hamburg that he became acquainted with Mattheson, a fertile composer and writer on musical subjects, whose *Teilkommener Kapellmeister* (1739) and *Die enfforte* (1740) are valuable sources for the history of music. The friendship of the two young men was not without some curious incidents. On one occasion they set out together on a journey to Lubeck, where the place of organist at one of the churches was vacant. Arrived at Lubeck, they discovered that one of the conditions for obtaining the place was the hand of the elderly daughter of the former organist, the celebrated Duxduch, who set the two candidates forthwith returned to Hamburg. Another adventure might have had still more serious consequences. At a performance of Mattheson's opera *Cleopatra* at Hamburg, Handel refused to give up the conductor's seat to the composer, who was also a singer, and was occupied on the stage during the early part of his work. The dispute led to an improvised duel outside the theatre, and but for a large button on Handel's coat which intercepted his adversary's sword, there would have been no *Messiah* or *In aid in Egypt*. In spite of all this the young men remained friends, and Mattheson's writings are full of the most valuable facts for Handel's biography. He relates in his *Enfforte* amongst other things that his friend at that time used to compose "into marvellous cantatas" of no great merit, but of these no trace now remains, unless we assume that a "Passion" according to St John (German words by Postel), the MS of which is at the Royal Library, Berlin, is amongst the works alluded to. It was composed in 1704. The year after this witnessed Handel's first dramatic attempt—a German opera, *Alcina*, performed at Hamburg on January 8, 1705, with great success, and followed a few weeks later by another work of the same class, *Nero* by name. In 1706 he left Hamburg for Italy, at that time still the great school of music, to which indeed Handel himself owed his skill and experience in writing for the voice. He remained in Italy for three years, living at various times in Florence, Rome, Naples, and Venice. He is said to have made the acquaintance of Lohr, of Alessandro Scarlatti, and of the latter's son Domenico, the father of modern pianoforte playing. His compositions during his Italian period were two operas, two oratorios, *Resurrezione* and *Il Trionfo del Tempo e del Disinganno*, afterwards developed into the English oratorio *The Triumph of Time and Truth*, and numerous other choral works. It was during these years that the composer's earlier or Italian style reached its full maturity, and that his name became widely known in the musical world. In the chief cities of Italy "il Sassone," as Handel, like his countryman Händel twenty years later, was nicknamed, was received with every mark of favour and esteem. But his own country also began to acknowledge his merits. At Venice in 1709 Handel received the offer of the post of capellmeister to the elector of Hanover, transmitted to him by his patron and staunch friend of later years Baron Kielmansegg. The composer at the time contemplated a visit to England, and he accepted the offer only on condition of leave of absence being granted to him for that purpose. To England accordingly Handel journeyed after a short stay at Hanover, arriving in London towards the close of 1710. Curiously enough he came as a composer of Italian opera, and in that capacity he caused his first success at the Haymarket with the opera *Rinaldo*, composed, it is said in a fortnight, and first performed on February 24, 1711. The beautiful and still universally popular air "Lascia ch'io pianga" is from this opera. A similar air in the form of a *serenade* occurs in *Alcina*. After the close of the season in June of the same year Handel seems to have returned to Germany for a short time, but the temptation of English fame or English gold

proved too powerful, and in January 1712 we find him back in London, evidently little inclined to return to Hanover in spite of his duties at the court there. Two Italian operas, the celebrated Utrecht *Te Deum* written by command of Queen Anne, and other works belong to this period. It was in such circumstances somewhat awkward for the composer when his desecrated master came to London as George I of England. Neither was the king slow in resenting the wrongs of the elector. For a considerable time Handel was not allowed to appear at court, and it was only through the intercession of his patron Baron Kielmsegge that his pardon was at last obtained. Commissioned by the latter, Handel wrote his celebrated *Water Music*, which was performed at a great fete on the Thames, and so pleased the king that he at once received the composer to his good graces. A salary of £900 a year granted to Handel was the immediate result of this happy consummation. In 1716 he followed the king to Germany, where he wrote a second German "Passion," the words this time being supplied by Brookes, a well known poet of the day. After his return to England he entered the service of the duke of Chandos as conductor of his private concerts. In this capacity he resided for three years at Cannons, the duke's splendid seat near Edgeware, and produced the two *Te Deums* and the twelve Anthems surmamed *Chandos*. The English pastoral *Airs and Galesias* (not to be mistaken for the Italian cantatas of that name written at Naples, with which it has nothing in common), and his first oratorio to English words *Esther*, were written during his stay at Cannons. It was not till 1720 that he appeared again in a public capacity, viz. in that of impresario of an Italian opera at the Haymarket Theatre, which he managed for the so called Royal Academy of Music. Senesino, a celebrated singer, to engage whom the composer specially journeyed to Dresden, was the mainstay of the enterprise, which opened with a highly successful performance of Handel's opera *Radamisto*. *Mirco Scerolo*, written in conjunction with Buononcini and Anstosi, *Tamerlane*, *Rodolinda*, and other operas composed for the same theatre, are now forgotten, only detached songs being heard at concerts. To this time also belongs the celebrated rivalry of Handel and Buononcini, a gifted Italian composer, who by his oblique was declared to be infinitely superior to the German master. The controversy raised a storm in the aristocratic teapots, and has been perpetuated in the lines generally but erroneously attributed to Swift, and in reality written by John Byron—

Some say, compared to Buononcini,
That My master Handel's but a mummy,
Others aver that he to Handel
Is scarcely fit to hold a candle.
Strive all this difference should be
Twixt Twiddle dum and Twiddle dee.

Although the contempt for music, worthy of Chesterfield himself, shown in those lines may seem absurd, they yet contain a grain of truth. Handel differed from his rival only in degree not in essence. In other words, he was an infinitely greater composer than Buononcini, but had he continued to write Italian opera there is no reason to conclude from his existing works of that class that he would have reformed or in any essential point modified the existing *genre*. The contest was therefore essentially of a personal nature, and in these circumstances it is hardly necessary to add that Handel remained victorious. Buononcini for a reason not sufficiently explained left London, and Handel was left without a rival. But an spite of this his connexion with Italian opera was not to be a source of pleasure or of wealth to the great composer. For twenty years the indomitable master was engaged in various operatic ventures, in spite of a rival company under the great singer Farinelli, started

by his enemies,—in spite also of his bankruptcy in 1737, and an attack of paralysis caused by anxiety and overwork. Of the numerous operas produced by him during this period it would be needless to speak in detail. Only the name of the final work of the long series, *Desdemona*, produced in 1741, may be mentioned here. That Handel's non success was not caused by the inferiority of his works to those of other composers is sufficiently proved by the fact that the rival company also had to be dissolved for want of support. But Handel was in more than one way disqualified for the post of operatic manager, dependent in those days even more than in ours on the patronage of the great. To submit to the whims and the pride of the aristocracy was not in the nature of the upright German, who even at the courts of the princesses of Wales would no language not other heard at courts when the talking of the ladies during the performance irritated him. And, what was perhaps still more fatal, he opposed with equal firmness the capricious and inartistic tendencies of those absolute rulers of the Italian stage—the singers. The story is told that he took hold of an obstinate *prima donna* and held her at arm's length out of window, threatening to drop her into the street below unless she would sing a particular passage in the proper way. Such argument was irresistible at the time, but then final results were equally obvious, in spite of Handel's essentially kindly nature and the truly assiduous he gave to those who really wished to learn. No wonder therefore that his quarrels with artists were numerous, and that Senesino deserted him at a critical moment for the enemy's camp.

It is a question whether Handel's change from opera to oratorio has been altogether in the interest of musical art. The opera lost in him a great power, but it may well be doubted whether dramatic music such as it was in those days would have been a proper mould for his genius. Neither is it certain that that genius was, strictly speaking, of a dramatic cast. There are no doubt in his oratorios—for in these alone Handel's power is displayed in its maturity—examples of great dramatic force of expression, but Handel's genius was in want of greater expansion than the economy of the drama will allow of. It was no doubt for this reason that from an inner necessity he created for him self the form of the oratorio, which in spite of the dialogue in which the plot is developed is in all essentials the musical equivalent of the epic. This breadth and depth of the epic is recognized in those marvellous choral pieces expressive either of pictorial detail (as the *gnats* and the darkness tangible and impenetrable in *Israel in Egypt*) or of the combined religious feeling of an entire nation. By the side of these even the finest solo pieces of Handel's scores appear comparatively insignificant, and we cannot sufficiently wonder at the obtuseness of the public which demanded the insertion of miscellaneous operatic arias as a relief from the incessant choruses in *Israel in Egypt* at the second performance of that great work in 1740. Handel is less the exponent of individual passion than the interpreter of the sufferings and aspirations of a nation, or in a wider sense of mankind. Take, for instance, the celebrated *Dean's March in Saul*. It is full of intense grief, in spite of the key of C major, which ought once for all to dispel the prejudice that sorrow always speaks in minor keys. Ever Chopin himself has not been able to give utterance to the feeling in more impressive strains. And yet the measure and decisive rhythm, and the simple diatonic harmonies plainly understate that here a mighty nation deplores the death of a hero. It is for the same reason that Handel's stay in England was of such great importance for his artistic career. Generally speaking, there is little connexion between politics and art. But it may be said without exaggeration that only amongst a free people, and a people having a national

life such as England alone had in the last century, such national epics as *Judas Macabeus* and *Israel in Egypt* could have been composed. In the same sense, the *Messiah* became the embodiment of the deep religious feeling pervading the English people, and Handel, by leaving Italian opera for the oratorio, was changed from the entertainer of a caste to the artist of the people in the highest and widest sense. The *Messiah*, indeed the musical equivalent of Milton's *Paradise Lost*. This leads us to another and equally important aspect of the same subject—the important influence of English poetry on Handel's works. Not only are some of the greatest names of English literature—Milton (*Allegro and Penseroso*), Dryden (*Alexander's Feast*), Pope (*St Cecilia's Ode*)—immediately connected with Handel's compositions, but the spirit of these poets, and especially of Milton, pervades his oratorios even when he has to deal with the atrocious doggerel of Motell or Humphreys. In addition to this Handel received many a valuable suggestion from the works of Puccini and other early English musicians with which he was well acquainted. No wonder therefore that Englishmen claim Handel as one of themselves, and have granted him honours both during his lifetime and after his death such as have fallen to the share of few artists. But in spite of all this it is impossible to deny that the chances of a national development of English music were, if not absolutely crushed, at least delayed for centuries by Handel. Under Elizabeth and James England had a school of music which, after the storms of the civil war, was once more revived by such masters as Pelham Humphrey and his great pupil Purcell. The latter, although cut off in his youth, had left sufficient seed for a truly national growth of English music. But Handel soon concentrated the interest of connoisseurs and people on his own work, and native talent had to abandon the larger sphere of the metropolis for the comparative seclusion of the cathedral. The following is a chronological list of Handel's English oratorios taken from the catalogue of his works appended to Mr J. Marshall's article in Grove's *Dictionary of Music and Musicians*, vol. i p. 657: *Ethra* (1720), *Deborah* (1733), *Athalie* (1733), *Saul* (1738), *Israel in Egypt* (1738), *Messiah* (1741), *Samson* (1741), *Joseph* (1743), *Hercules* (1744), *Belshazzar* (1744), *Oraculous* (1746), *Judas Macabeus* (1746), *Alexander's Feast* (1747), *Joshua* (1747), *Solomon* (1748), *Semirame* (1748), *Theodora* (1749), *Jephtha* (1751), *The Triumph of Time and Truth* (1757). The sequence of these dates will show that the transition from Italian opera to sacred music was very gradual, and caused by circumstances rather than by premeditated choice. It would lead us too far to enter here into the genesis of each of these works, but a few remarks must be added with regard to Handel's *summa opus* the *Messiah*. It was written in twenty-four days and first performed April 18, 1742, at Dublin, where Handel was staying on a visit to the duke of Devonshire, lord-lieutenant of Ireland. Its first performance in London took place on March 23d of the following year. Its introduction into Handel's native country was due to Philip Emanuel Bach, the son of the great Bach, who conducted it at Hamburg. At Berlin it was for the first time given in April 1766, under the leadership of Adam Hilfer, who also introduced it a few months later at Leipzig against the advice of all the musicians of Saxony. At the Berlin performance Signora Carrara, the celebrated singer, seated in the first pit an aria by Telesio, in which, according to a contemporary account, "she took much trouble to please the public, and the bravura passages of which she delivered with great success." Two years before this had taken place the great Handel commemoration at Westminster Abbey, when on the third day of the festival, May 29, 1748, the *Messiah* was splendidly performed by an orchestra and chorus of 525

performers. In the appreciation of Handel England thus went far in advance of Germany. The remainder of Handel's life may be told in few words. Owing to the machinations of his enemies he for a second time became bankrupt in 1745, but nothing, not even his blindness during the last six years of his life, could daunt his energy. He worked till the last, and attended a performance of his *Messiah* a week before his death, which took place on April 14, 1759. He was buried in Westminster Abbey. His monument is by Rubini, the same sculptor who modelled the statue erected during Handel's lifetime in Vauxhall Gardens.

Handel was a man of character and high intelligence, and his interest was not, like that of too many musicians, confined to his own art exclusively. He liked the society of politicians and literary men, and he was also a collector of pictures and articles of vertu. His power of work was enormous, and the list of his works would fill many pages. They belong to all branches of music, from the simple air to the opera and oratorio. His most important works of the two last-named classes have already been mentioned. But his instrumental compositions, especially his concerti for the organ and his *suites de pieces* for the harpsichord, ought not to be forgotten. Amongst the contrapuntists of his time Handel had but one equal—Bach. But he also was a master of the orchestra, and, what is more, possessed the rare gift of genuine melody, unfortunately too often impeded by the innumerable embellishments of his arias. This extraordinary rapidity with which he worked has been already referred to. It is true that when his own ideas failed him he helped himself to those of others without the slightest compunction. The system of wholesale plagiarism carried on by him is perhaps unprecedented in the history of music. He pilfered not only single melodies, but frequently entire movements from the works of other masters, with few or no alterations and without a word of acknowledgment.

A splendid collection of Handel's MSS. in six volumes in all, is in the possession of her Majesty at Buckingham Palace. The Fitz William Museum at Cambridge also possesses seven volumes, mostly sketches and notes for greatest works, in the composer's hand writing. The German and English Handel Societies (the latter founded in 1848 and dissolved in 1848) have issued critical editions of his more important works. These biographies of Handel deserve mention.—An Englishman, Mainwaring, *Memories of the Life of the late G. F. Handel* (1870), a German, H. Victor Schmidt, and a German, Hett Chytrands. (F. H.)

HAND TOOLS. Within the limits of the present article it would be impossible to describe even the majority of the instruments which may come under this designation, including as it does (in its popular if not in its technical sense) the whole of the appliances used by the handicraftsman in the treatment, by means of his muscular energy, of the natural substances used in the arts and manufactures,—whether in the preliminary operations of setting-out and measuring his materials, in reducing his work to the required form by cutting tools or otherwise, in gauging it and testing its accuracy, or in duly securing it whilst being thus treated. Omitting therefore the large but by no means unimportant class of measuring and gauging instruments, straight edges, templates, &c, we will confine our attention to examples of those in the use of which an actual expenditure of force is necessary. According to the structure and other properties of the materials either by impact, by pressure, or by cutting, the last being effected sometimes with impact and sometimes with pressure. The principal tools acting purely by impact are noticed under HAMMER (q. v.) Those which depend solely on pressure are for the most part of an auxiliary character only, and their consideration will be deferred till we have glanced at a few of the much more numerous and more important class known as cutting or edge tools.

It should be observed that the term "cutting" is applied to processes which have but little in common, the great differences of structure in the materials operated upon demanding equally great differences in the modes of effecting the desired end, which is in almost all cases the forcible separation of their particles in some regular and definite manner. If we regard, for example, the action of a sharp knife upon a piece of chalk as one of true cutting, *i. e.*, the separation of its particles by the forcible insertion of a wedge-like blade of superior hardness to itself,—we shall find that in by far the larger proportion of instances this simple action is rendered complicated, either through the substance under treatment being insufficiently compact to afford in itself the necessary resistance, or through its want of homogeneity causing a tendency in it to part more readily in some directions than in others. Thus all kinds of wood and the generality of both vegetable and animal substances, being cellular or fibrous in their structure, offer so much less resistance in a direction parallel to their fibres than in one transverse to them that in the former case many of them may be parted by fissure without any true cutting at all. So also with crystalline materials—as is beautifully exemplified by the diamond, which lends itself to cleavage in certain planes in the most perfect manner, though the steel chisel which is employed for the process is very much inferior in hardness to itself. Metals also are frequently not homogeneous; indeed they are sometimes said to be fibrous in structure, but it is only to a very limited extent, if at all, that they are so, and their great natural tenacity even then prevents the separation of their particles except by a true cutting process. Lastly, some stones and minerals, such as sandstones, are said to be cut, though they are formed of material considerably harder than the tools which are used upon them, the fact being that their hard particles are not cut at all, but are merely separated from one another when the cementing material which holds them together is compelled to give way.

I. Cutting or Edge Tools.—Those, the term "cutting" being thus qualified, are mainly of two classes—(1) cutting tools used with impact, and (2) cutting tools used mainly with pressure. These again may be subdivided into tools used (1) for wood and soft materials, (2) for metal, and (3) for stone and hard substances.

1. 1.—Wood-tools cutting by impact comprise all the varieties of axes and adzes, such as the ordinary English pattern of carpenter's

FIG. 1.—Axes.

axe (a, fig. 1), the woodman's falling axe (b), the wedge axe (c) (which was one of the first American improvements in edge tools introduced into Europe), and the shipwright's adze (d), which last

FIG. 2.—Chisels.

is a particularly rapid and efficient tool in skilful hands. All these when used in the direction of the grain of the wood act by cleaving rather than by cutting, except when the thickness of the chip

removed is so small that its transverse strength is inferior to the lateral tenacity of the fibres. So also do chisels and gouges when driven by blows from a hammer or mallet. The ordinary mortise chisel (a, fig. 2) and the socket chisel (f) are specially adapted for being used in this way.

2. In the case of *metal* tools their hardness in general precludes the possibility of employing upon them any tools corresponding to the above. If we except a few special tools such as plumbers' knives, *etc.*, chisels will be found to be almost the only tools in this class. A blacksmith's chisel (g) held in a hazel withe, and used for hot iron, and some common forms of chisel for chipping it cold are shown in fig. 2, these being known as a chipping chisel (h), a cross-cut (j), a diamond point (k), and a round nose (l).

3. Tools of this class for *stone* also consist chiefly of chisels, the mason's chisel (m) varying greatly in width of edge according to the variety of stone and the depth of the cut to be taken. Frequently they are brought quite to a point like the mason's pick, when they cease to be cutting tools from our point of view. The jumper (w), employed for rock drilling, with which the hole is produced by means of successive cuts radiating in all directions from its centre, which are delivered with the impact due either to its own weight or to the blows of a hammer on its outer end, is also a form of chisel.

II. Edge tools operating by pressure.—Of this class the ordinary chisel-knife is perhaps the best known example. A sharp knife serves well for showing the different kinds of treatment by cutting or by fissure to which any particular wood or other moderately soft material is capable of submitting itself. The "thickness" of the cutting edge, or in other words, the angle which the facing-edges places which include it form with one another, the degree of smoothness or roughness of edge which best effects the clean division or separation of the fibres, and the possibility or otherwise of producing a smooth surface by "scrapping," can all to a great extent be judged of with the aid of a knife. And the subject is by no means an unimportant one. Consideration of the action which takes place at the edge of a cutting-tool, and the extent to which this action produces on particular portions of it are frequently of service in enabling us successfully to meet the special cases which arise in practice, and may sometimes guide us towards remedying the defective action of the hand-tool in use for ordinary work. America has long taken the lead in originating thoughtful improvements of this kind, and the result is apparent in the rapid manner in which the use of edge tools and appliances of American patterns is now everywhere extending.

1. In fig. 3 are shown a few of the ordinary English wood-tools. They include the firmer chisel (o) used by carpenters, and a carver's chisel (p) and gouge (q). A wood-engraver's scraper (r) and knife (s) are examples of special tools, being intended only for cutting hard wood in a direction transverse to the grain, cross-cut blocks of box-wood being alone used for the finer kinds of wood-engraving. The spoke-shave (c) affords a good example of what has just been said as to the result obtainable by a well-directed effort towards the improvement of an old established hand tool. In the form figured (2), which is the ordinary one in use in England, the blade or "iron" is rather complicated in shape and is not very easy to sharpen;

FIG. 3.—Chisels, planes, and saws.

each successive sharpening moreover impairs the efficiency of the tool by widening the "mouth," the unusual wear of the wooden sole, which very speedily takes place, having also a share therein. Thus three essential conditions of a good cutting-tool, *viz.*, constant maintenance of its proper action, durability of the parts exposed to wear, and facility in sharpening are all unfulfilled. On the other hand these manufactured in America fulfil them admirably: iron is substituted for wood as the material for the sole and handle, and the blade, which is merely a piece of flat steel, is firmly held in its place by a set screw, half a turn of which at once releases it.

Planes are to be met with in great variety, the most useful for ordinary carpentry being the jack plane (w), the trying plane, and the smoothing plane (v). Of these the first is used for taking off the rough; or for reducing the thickness of a board; the second, which resembles it, except in being of much greater length, for correcting inequalities of the surface; and the third, as its name implies, for the final smoothing. Planing being

chiefly performed in the direction of the grain of the wood, a smooth surface can only be obtained when its fibres are cut instead of being allowed to separate from one another by cleavage, the tendency to which, in soft woods more especially, must therefore be carefully resisted. With this object the planes above mentioned, and many others also, are provided with what is called a "double iron," an inverted blade or "iron" being securely attached to the upper side of the cutting iron, with its edge at a short distance only from the cutting edge. It depresses the fibres so that they are continuously broken transversely, and so splits into the fibres of which it is composed from tearing up those in advance of the cut. The width of the "mouth" or space between the cutting edge and the portion of the plane stock which is also kept as small as possible in the planes intended for smoothing is to be increased to the utmost their breaking action by supporting the as yet undisturbed fibres in advance of the cutting edge. Wear of the mouth is sometimes prevented by letting in a narrow piece of iron or forming the stock entirely of iron or steel. Planes of great length, which are known as jointers, are used for some purposes, coarser planes of this kind being sometimes over 5 feet long.

The use of moulding planes (see) is indicated by their name. Each is adapted only for producing one particular pattern of moulding. Follows and round resemble them, but have the cross section of their soles simply concave and convex respectively, work which is hollowed or rounded in the direction of its length comprises planes employed, each of which, as ordinarily made, cannot deviate much from its own particular curvature. American joiners have, however, again stepped in, and have got over the objection by making the sole of a spring plane of steel, which can be adjusted to any curve either convex or concave within very wide limits, so that this one tool takes the place of an entire set of ordinary compass planes. Planes are somewhat complicated planes which are used for forming grooves of various widths, depths, and distances from the edge of the work.

The "pitch" of a plane is the angle at which the blade or iron is inclined to the sole, and the inclination is varied in wood that is soft or hard. Some of the forms, indeed, have their iron so nearly erect that their action is what would ordinarily be described as scraping and not cutting, a difference which appears to be undetectable, but is due to the structure of the materials which can be so treated, and not, as has been suggested, to any peculiarity in the form of the cutting edge. The action of a plane in shaving smooths the surface, and this is the action of a bar that is oblique, being bent under the microscope to be beautifully clearly sliced, though the blade is applied at a great angle to the plane of the cut.

The following may be taken as good examples of saws—the hand saw (A), the rip saw and half rip (B), which differ from it only in size and size of tooth, and the dovetail saw and tenon saw (C), of which the first has all the sufficient stiffness of blade to resist the force exerted in using them, and the last is too thin and unable to do this without the support of the iron or brass "back," which of course limits the depth to which a cut can be made with them. The rip and cross cut saws are the largest representatives of saws used by hand, being employed for large work, such as cutting timber in the log, and worked generally by two men. Frame saws of all sizes, from those of 8 feet to 10 feet used by jet sawyers down to the flat saws of but a few inches in length and scarcely thicker than water glass, and many others, for cutting out curves, must also here be mentioned amongst hand-saws, though technically they are not included in the term.

In fig. 4 some details of saw teeth are shown. A being the usual form for all the smaller kinds that are made, angle branded, which is used lower as well as also to the angle at which the "set square" (B) is used in binding the teeth to the edge of a piece, while B is the gullet tooth, for use in cutting the grain of the wood, and C the ordinary cross cut tooth, for transverse cuts. It is evident that a saw tooth which is well adapted for producing a clean cut in one of these directions would be ill adapted for doing so in the other, at least in the case of the gullet tooth. The result in sawing with the grain the regularity and the uniformity with

FIG. 4.—Varieties of saw teeth.

which, the direct action of fibres sliced off by each tooth puts from the fibres by its cut (owing to the slight lateral cohesion already alluded to) assists in the operation, and a fairly clean cut results. But in cases cutting special provision is required for cleanly dividing the fibres at each side of the cut, after which the removal of the interfering flag tooth, for the saw is then the grain of the wood is faster than by cutting. The rationale of the gullet-tooth (B) is that, as the hook-chisel-like edges of the teeth being well adapted for slicing the fibres of the wood transversely, and for this it leaves little to be desired, the cross cut tooth (C), consisting as it is of a series of lancet-like points acting alternately at each side of the

cut, divides the fibres, but has no proper provision for their after removal, and the hand saw tooth (A) is a sort of compromise between the two (at least if we neglect the rounded portion of the gullet tooth, which does not affect its edge), so that it can be used either with the grain or across it, though not with the best possible results. The cross cut tooth (D), on the other hand, provides both for the clean separation of the fibres and the removal of them fragments.

The "set" of a saw is the slightly increased width given to its toothed edge by alternately bending the teeth towards the opposite sides of the blade, the extent to which this is done, or the width of the "set" (as it is called), therefore determines the amount of material which is now wastes in forming its cut. The more perfect its action, the smaller being the amount of set required to make it work freely, and the less the power expended in working it.

Some boring tools for wood are shown in fig. 5. The hand auger (E) is adapted only for soft woods, the gimlet, either in its plain or its twisted form (F), has little to be said in its favour, and the shell-auger (G) requires an expenditure of force altogether disproportionate to the results produced by it. The screw auger is an improvement upon all, although this, as generally made, still leaves a good deal to be desired as regards consumption of power. But the wood worker's main stand by for boring is the stock or brace (H) and set of bits. These ordinarily supplied for

FIG. 5.—Boring tools.

losing across the grain consists mainly of centre bits (I) for the large and small bits for the smaller holes, and a set of what are thoroughly efficient tools—also now bits (J), which resemble shell augers and share their defects, for boring with the grain. The English wood boring tools indeed offer a considerable field for improvement. Imported substitutes for the above are already to be met with, amongst others being the twisted centre bits, of which the stoma resembles the twist drill referred to below, and the expanding centre bits, both of which appear to be an advance in the right direction, though they have not as yet come largely into use.

2. Cutting tools for metal analogous to the foregoing are lathe saws as regards surface work. These differ from the lathe saw in that the case of those used for the harder metals—the greatly increased thickness of their edges. Piles of various saw sections, lengths, and degrees of fineness of tooth, and shapes (which are usually thin knife-edges, made not unimportantly from worn out files by sharpening them at the extremity), constitute almost the only edge tools at the disposal of the fitter or machinist for finishing work that he has roughly surfaced with his chipping chisels. For boring he has drills of various sizes, too often of the antiquated pattern (K), which in boring deep holes would be kept straight, though the very superior twist drill (L) is now often to be met with. Countersinks, either of the flat (M), rose (N), or semi-horn pattern (O), are generally included with carpenter's sets of bits, for enlarging holes in metal work to receive the heads of screws. They are not used with the wooden bits as figured above. The small's base resembles it, but is all made of iron, and a heavy pressure is applied to its upper end and by means of a screw. A tachet lance (P) is a more powerful instrument, used to remove the heads of screws, the saw file being sharpened. Small holes can be drilled under a light pressure with rapid motion on the part of the drill, which is then generally of the form K, but sharpened from both sides, so as to form a knife-edge which opposes equally well in whichever direction the drill revolves. The drill bar, of which the string takes one turn round a bolt or screw on the stem of the drill itself or on its holder, is a ready means of obtaining a rapid reciprocating motion for this purpose, and is not yet superseded, though various ingenious substitutes have been devised. For enlarging holes throughout their length in bones or metals as used, these may be either simply half round or polygonal in section, or may have any desired number of longitudinal grooves, each of which forms a cutting edge when the tool moves successive portions for the sides of the hole. An enlarged parallel rimmed with four flutings is shown at R, the square end when in use being inserted in a hole in the centre of a piece, which allows the flutes to remove the waste.

An internal screw thread is formed in an analogous manner by a

tap, which bears on its surface the counterpart of the required thread, so that by successive cuts it produces a helical groove of the correct form and depth. Such a tap (S) is represented in the engraving, together with a diagram of its cross section, showing the three cutting edges by which it removes the thread in rotation. These such taps constitute a set for any one size of screw, the first being known as a taper, the second as an intermediate, and the third

Fig. 6.

as a plug-tap, this last being almost parallel throughout. By a reverse process with dies fixed in a stock (T, fig. 6) external screws are cut, the particular form shown being the improved pattern of Sir J. Whitworth, who has done much to correct the faults of the earlier screwing tools. Screw plates, however, some of which cannot be regarded as cutting tools at all, are still much used for small and fine screw threads.

Cutting pliers and cutting nippers (U) have a pair of knife edges so arranged as to work exactly opposite to one another, — the handles on being tightly grasped, affording sufficient leverage for these edges to be forced to a short distance into the two opposite sides of a nail or wire, which, if of small diameter or of soft metal, can thus be cut around. Pincettes are an ingenious device which the extensive use of wrought-iron tubing for gasfitting has rendered necessary. They effect their object by cutting a groove round the tube to a sufficient depth to enable it to be fractured at the desired point.

8. *Stone and hard materials cannot in general be treated by cutting tools simply with hand pressure, thought some of the softer kinds of stone are carved with chisels used almost or altogether without impact, and are sawn with toothed saws resembling the cross-cut saws used for wood. Glaziers' diamonds were till recently the only tools for producing the peculiar "cut" requisite for starting the clean fracture by which sheet glass is divided, thence, however, being a case of shears rather than of true cutting. But of late years steel glass cutters have been introduced which act—as long as the sharpness of their edges is maintained—in a manner precisely similar. In one form of these glass cutters (V) a cast-iron handle carries at its extremity a small freely revolving wheel of carefully hardened steel, round the circumference of which is the cutting edge, which can be sharpened on an oilstone when necessary. The so-called cut is produced by simply running this with a light pressure over the surface of the glass. Diamonds, however, are used for cutting glass, stone, &c., by actually detaching their particles; writing diamonds and diamond drills have been kind of action.*

II. *Hand-tools without cutting action.*—With the exception of hammers and a few tools which are dependent on impact,—such as cleaving wedges amongst wood tools, and enbousing and similar punches amongst those for metal,—tools of this class play in general only a subsidiary part to some cutting or other process.

Amongst those used with pressure which cannot be considered as auxiliary may be instance—draw-plates, with which wire is made by drawing it through holes of conical form and of successively smaller diameters till the required size or "gauge" is reached; and burnishers, which reproduce on metals softer than themselves their own highly polished surfaces. Both of these act by inducing a flow of the metal under treatment, rather than by shearing or splitting by impact, great force is required in proportion to the extent of the action. Metal shears and cutting punches of all kinds have been omitted till now, as their mode of operating cannot be regarded as true cutting from any point of view. It may be more correctly described as tearing, more or less completely localized according to circumstances. The ordinary sheet-metal shears (W) merely resemble very powerful scissors, and their action being quite local, they serve well for dividing plates or other thin sheets for which alone they are suitable. Block shears (X) not with additional leverage, and can consequently be used for rather thicker metal, the upper bar being replaced by a long straight handle, and the lower one by a stake which can be firmly fixed in a block of wood, or otherwise. With these the tearing action begins to be apparent, though its imperfection is of no great importance with the thicknesses of metal capable of being treated by any hand shears (for some tools of this class, which by hydraulic or other means accumulate the power of one man to a sufficient extent to operate on bars or

plates of comparatively great substance, are machines rather than hand tools, and in their case the mere slowness of the operation produces better results than would otherwise be obtained). The same may be said of the various punches used in combination with dies or bolsters, as in the punching bar (Z), of which the action exactly resembles that of shears, the punch taking the place of the upper blade, and the bolster that of the lower one.

Of subsidiary tools (figs. 7) the vice is an absolute essential for the generality of metal work. The ordinary tail-vice (A) used by mechanics has not yet been largely superseded, though many ingenious arrangements have been devised for remedying its main defect, viz., the want of parallelism in the movement of the jaws. The English parallel vice (B) has not this objection, but its construction is not good mechanically, and it is but little used except for small work. In some patterns of vice, jaws are provided with a horizontal adjustment so as to grip tapering or other irregular forms, and in others the whole body of the vice can be swivelled

Fig. 7.

either vertically or horizontally. Hand-vices are used in the manner implied by their name, without being attached to a bench like the foregoing. An ingenious form of hand-vice (A) is shown in fig. 7. The screw wrench (B), which is used for turning nuts, &c., of various sizes has of late been deservedly the subject of various improvements in which weight is sought to be saved without sacrifice of strength; and the shifting spanner, of which the duty is the same, has led to the exercise of much ingenuity without any perfectly satisfactory solution of the problem how it may best be constructed. The merit and simplicity of the ordinary screw-driver, on the other hand, are well known.

Instances of tools which afford a powerful grip by simple means are the blacksmith's tongs (C), the vice-chop tongs (D), the pliers (E), and the pincettes (F). A very powerful modification of the last-mentioned tool has lately been introduced into use under the name of the nail-puller (G). With this ingenious instrument very largely increased leverage is obtained, and the pull is given in a direction much more advantageous to the attainment of the desired object. (C. F. S. S.)

HANG-CHOW-FOO, a city of China, in the province of Che-Kiang, about 2 miles north-west of the Tsoen-tang-Keang, at the southern terminus of the Imperial Canal, by which it communicates with Peking. It lies about 160 miles south-west of Shanghai, in 30° 20' 20" N. lat. and 120° 7' 27" E. long. Towards the west is the Si-han, or "Western Lake," a beautiful sheet of water, with its banks and its surface traversed by gaily-painted pleasure boats. To the Chinese it is a very paradise. Exclusive of extensive and flourishing suburbs, the city has a circuit of 12 miles; its streets are well-paved and clean; and it possesses a large number of arches, public monuments, temples, hospitals, and colleges. It has long ranked as one of the great centres of Chinese commerce and Chinese learning. In 1869 the silk manufactures alone were said

to give employment to 60,000 persons within its walls, and it has an extensive production of gold and silver work and tinware paper. On one of the islands in the lake is the great Wan-lan-ko pavilion of literary assemblies, and it is said that at the examination for the second degree twice every three years from 10,000 to 15,000 candidates come together. In the north-east corner of the city is the Nestorian church which was noted by Marco Polo, the facade being "elaborately carved and the gates covered with elegantly wrought iron." There is a Roman Catholic mission in Hang-chow, and the Church Missionary Society, the American Presbyterians, and the Baptists have likewise stations. The local dialect differs from the Mandarin mainly in pronunciation. The population, which is remarkable for gaiety of clothing, was formerly reckoned at 2,000,000, but is now variously estimated at 300,000, 400,000, or 800,000.

Hang-chow foo is the Kuvu of Marco Polo, who describes it as the finest and noblest city in the world, and speaks enthusiastically of the number and splendour of its mansions and the wealth and jurisdiction of its inhabitants. According to his authority it had a circuit of 100 miles, and no fewer than 19,000 bridges and 3000 baths. The name Kuvu, which appears in *Wang-tse Kuvu*, in *Ben Bute*, in *Khuan*, in *Ordericus*, in *Chumay*, and elsewhere as *Campey* and *Cassay*, is really a corruption of the Chinese *Kung* as capital, the same word which is still applied to Peking. From the 10th to the 13th century (960-1279) the city, whose real name was then Lung-nu, was the capital of Southern China and the seat of the Sung dynasty, which was destroyed by the Mongolians shortly before Marco Polo's visit. Up to 1861, when it was laid in ruins by the Taipings, Hangchow continued to maintain its position as one of the most beautiful and the most important, and though for a time it lay comparatively desolate, it has considerably recovered within recent years. It is the seat of the governor of Che Kiang, but the governor general or viceroy for Che Kiang and Fuh Kien is now located at Tschow. See Colonel Yule's edition of Marco Polo, vol. i, for a plan of the city and further details.

HANKA, WENZESLAUS or WAKLAW (1791-1861), a Bohemian philologist, was born at Eciencowes, a hamlet of eastern Bohemia, on June 10, 1791. He attended the village school in winter only, being occupied during the summer on his father's farm. While still young he acquired a knowledge of Polish and Serbian from some soldiers billeted in his neighbourhood, and in 1807 he was sent to school at Koniagatz, to escape the conscription. Proceeding then to Prague, he engaged in the study of philosophy, and founded a society for the cultivation of the Czech language. At Vienna, where he afterwards studied law, he established a Czech periodical, and in 1813 he made the acquaintance of Dobrowsky, the eminent philologist. On September 16, 1817, Hanka made the discovery of some ancient Bohemian manuscript poems of the 13th and 14th century in the church-tower of the village of Kralowetz, or Konigstul. These were published in 1818, under the title *Kralowetzky Zborek*, with a German translation by Swoboda. Great doubt, however, was felt as to their genuineness, and Dobrowsky, by pronouncing *The Judgment of Lubusa*, another manuscript found by Hanka, an "obvious fraud," confirmed the suspicion. But some years afterwards Dobrowsky saw fit to modify his decision, and in 1840, after a careful examination of the manuscripts by two eminent antiquaries, Hanka was ultimately vindicated. A translation into English, *The Manuscript of the Queen's Court*, was made by Wistec-law in 1852. The originals were presented by the discoverer to the Bohemian Museum at Prague, of which he was appointed librarian in 1818. In 1848 Hanka took part in the Slavonic congress and other peaceful national demonstrations, being the founder of the political society, Slovanska Lipa. He was elected to the imperial diet at Vienna, but declined to take his seat. In the winter of 1848 he became lecturer and in 1849 professor of Slavonic languages in the university of Prague, where he died, January 12, 1861.

His chief works and editions are the following—*Hankow Tsau* (1818), a volume of poems, *Slovany skladane* (1817-1828), in 5 vols., "a collection of old Bohemian poems, chiefly from unpublished manuscripts," *A Short History of the Slavonic Peoples* (1818), *A Bohemian Grammar* (1825) and *A Polish Grammar* (1848),—these grammars were composed on a plan suggested by Dobrowsky. *Yen* (1821), an ancient Russian epic, with a translation into Bohemian, a part of the Gospels from the Khema manuscript in the Chigoritz character (1846), the old Bohemian Chronicle of *Bohuslav* (1848) and *Pracep Zigu* (1848), *Evangelium Octomus* (1858).

HANKOW (that is, the "Mouth of the Han"), the great commercial centre of the middle portion of the Chinese empire, and since 1858 one of the principal places opened to foreign trade. It is situated on the northern side of the Yang-tse kiang at its junction with the Han river, about 450 miles west of Shanghai in 30° 32' 51" N lat and 114° 19' 55" E long, at an absolute height of 150 feet. By the Chinese it is not considered a separate city, but as a suburb of the now decadent city of Hanyang, and it may almost be said to stand in a similar relation to Wu chang the capital of the province of Hupeh, which has immediately opposite on the southern bank of the Yang-tse kiang. Hankow extends for about a mile along the main river and about two and a half along the Han. It is protected by a wall 18 feet high, which was erected in 1863 at an expense of £250,000, and has a circuit of about 4 miles. In 1801 the port was declared open by James Hope and Sir Harry S. Parkes, C.B., and the site of a British settlement was selected in the east end of the town, with a river frontage of 2400 feet, and a depth of from 1200 to 1500. The building area, divided into 108 lots, was quickly bought up, and houses after the Shanghai style were erected. Leases were granted to foreigners as well as to British subjects. A municipal council was formed, and by 1863 a great embankment and a roadway were completed along the river, which has the awkward fashion of rising as much as 50 feet or more above its ordinary levels, and not infrequently, as in 1849 and 1866, lays a large part of the town under water. On the former occasion little was left uncovered but the roofs of the houses. The success of the foreign settlement has not been so great as was anticipated, even in 1866 the number of foreign residents was 125 instead of 100 as in 1863. Chinese merchants have rapidly got even the foreign trade into their hands. In 1873 they began to run steamers on the river, in 1875 they purchased the property of the Shanghai Steam Navigation Company, and in 1876 they had 67 steamers flying the national flag. Besides tea, which is the staple, the exports of Hankow are least tobacco, of which 6,700,000 lb was sent to Europe in 1876, raw silk mainly obtained from Szechuen, Shuhai, gall-nuts, and musk. Of this last the quantity was as much as 2937 lb at £20 sterling per lb. Tea was first sent direct to London in 1864-65, in 1876 this market received from Hankow no less than 2,540,000 lb out of a total export of 86,402,271 lb. The Russian merchants, who are fixing their brick-tea factories in the town, obtained 12,844,476 lb in the same year. They send their goods by water to Tientsin, and thence to Kalgan partly by land and partly by water. A public assay office was established at Hankow in 1864. The Roman Catholics, the London Missionary Society, and the Wesleyans have all missions in the town, and there are two missionary hospitals. Before the Taiping wars, the full brunt of which fell on this part of the country, the sister cities of Hankow, Hanyang, and Wu-chang-fu had a population, it is said, of over 5,000,000. At present Hankow has from 600,000 to 800,000 (Somersoffsky says only 300,000), and the other two from 400,000 to 700,000.

HANTLEY, a market town and municipal borough of Staffordshire, England, is situated in the centre of the pottery district, 2 miles ENE of Stoke-upon-Trent, and 18 miles N of Stafford. It is indebted for its rise and

prosperity to its pottery manufactures, which include porcelain, encaustic tiles, and earthenware, and gave employment to the greater part of the population, women and children being employed almost as largely as men. In the neighbourhood coal and iron are obtained. The streets, which are paved with brick, are wide and regular, and in the suburbs there are a number of fine villas. The principal public buildings are the six churches (St John's being a handsome structure with a tower 100 feet in height) and the dissenting chapels, the town hall, the mechanics' institute, the museum, the theatre, and the national and board schools. There is also a flourishing Government school at Hanley, which includes the former township of Shelton, received a municipal constitution in 1857. It is the central and most important of the group of towns constituting the parliamentary borough of Stoke-upon-Trent. The population of Hanley in 1861 was 31,963, and in 1871 39,976.

HANNAY, JAMES (1827-1873), critic, novelist, and publicist, was born at Dumfries in 1827, and came of the Hannays of Sorbie, an ancient Galloway family. He entered the navy in 1840 and served till 1846, when he adopted literature as his profession. In 1857 Hannay contested the Dumfries burghs in the Conservative interest, but without success. He edited the *Edinburgh Courant* from 1860 till 1864, when he removed to London. In July 1868 he was appointed British consul at Barcelona, a post which he occupied till his death on the 8th of January 1873. While at Barcelona he contributed to English periodicals, and his letters to the *Pull Mull Gazette* ("From an Englishman in Spain") were highly appreciated. Hannay's best books are *Singleton Fontenay, Satire and Satire vnt, Eustace Conyers*, and *Essays from the Quarterly Review*. *Satire* not only shows, in every conception of the great structure of the year, but is itself instinct with wit and fine satirical power. The book sparkles with epigrams and apposite classical allusions, and contains admirable critical estimates of Horace (Hannay's favourite author), Juvenal, Erasmus, Sir David Lindsay, George Buchanan, Boileau, Butler, Dryden, Swift, Pope, Churchill, Burns, Byron, and Moore. The *Essays* are full of learning and historical knowledge, and are lit up with sunny humour and brilliant flashes of wit and poetry. Hannay passionately admired three things—learning, literary genius, and good blood. He showed great talent, and his story and romance of the *Scottish families*, his wonderful skill in matters of heraldry and genealogy is recognized by highly competent authorities (see *Mason's Life of Milton*, vol. i p. 8). He was a ripe Latin scholar, and his style is marked by grace, vivacity, and poetical feeling. He was intimate with his leading literary contemporaries, and wrote the valuable notes to Thackeray's *English Humors*.

In addition to contributions to *Punch* and the leading reviews, Hannay issued the following works—*Diavolo and Gray, Oliva One, and Hearts as a Truism* (1848), *Kiku Dobbe* (1849), *Sketches in Ultramarine, Singleton Fontenay* (1850), an edition of the *Poems of Edgar Allan Poe*, to which he prefixed an exquisite essay on the poet's life and genius (1851), *Serena and Stella and Seta and Salvia* (1854), *Eustace Conyers* (1855), *Poems from the Quarterly Review* (1861), *Characters and Criticisms*, consisting mainly of his contributions to the *Edinburgh Courant* (1866), *A Course of English Literature* (1868), and a family history entitled *The Hundred Years of a Norman House* (1867).

HANNIBAL Hannibal was a very common Cathaginian name. Its final syllable *bal* occurs repeatedly, as a suffix, in Punic names, and is in fact taken from the chief Phœnician deity, Baal. The entire name denotes, according to a probable interpretation, "the favour of Baal."

The famous Hannibal, the hero of the Second Punic War, was the son of Hamilcar. Barca, and was born in 247 B.C. He and his two brothers, Hasdrubal and Mago, were called by the father "the lion's brood." At the age of nine he

begged his father, who was leaving Carthage for Spain, to take him with him. The request was granted, but not before he had sworn at that father's bidding on the altar of sacrifice eternal enmity to Rome. That vow determined his life's future. In Spain he was bred up in camps under his father's eye. He was present at the battle in which his father fell in 228 B.C., being then in his nineteenth year. Hamilcar's son-in-law, Hasdrubal, succeeded to the command. Eight years afterwards, in 221 B.C., he was struck down by an Iberian assassin. Meantime the young Hannibal had proved himself thoroughly able both "to obey and to command." It was a matter of course that the soldiers with one voice at once hailed him as their general.

His first object was to complete the work of his father and his father's successor. Spain, he felt, must be more thoroughly overawed, if it was to be a base of operations against Rome. He pushed into the heart of the country, crossed the Tagus, and crushed the resistance of the tribes of the interior. Two campaigns sufficed for the conquest of all Spain to the south of the Ebro, except Saguntum, a town considerably south of the Ebro and some way to the north of the modern Valencia. It was a Greek colony, then Iapyrgium (Zante), and had grown into a rich and prosperous place, but, what was now far more important, it was in friendly relations with Rome. To attack it therefore would be like throwing down the gauntlet to the Roman senate and people. But Hannibal was able to tell the home Government at Carthage that the Seguntines were molesting Cathaginian subjects in the neighbourhood. Without awaiting an answer, he began the siege. Roman ambassadors at the solicitation of envoys from Saguntum landed on the coast, but were told by Hannibal that he could not see them. They went on to Carthage, but their remonstrances, though the subject of a long debate, were in vain. Eight months passed away, and Saguntum, after a gallant defence, was forced to surrender. Hannibal got a rich booty for his army, and went into winter quarters at New Carthage (Cartagena). Again a Roman embassy went to Carthage and insisted on his being given up. The demand was refused. By the close of the year 219 B.C. the Second Punic War was in fact begun.

Hannibal's resolution was now taken. He prepared at once to invade Italy. He had a numerous and efficient army and a well-fitted exchequer. All who shrink from them that he had a large force. In the spring of 218 B.C. he began his great march from New Carthage with an army of 90,000 foot, 12,000 horse, and 87 elephants. The Ebro was easily crossed. In the country beyond he had some fighting with the native tribes, and thence he left Hanno, with a force of 10,000 foot and 1000 horse to secure the passes between Spain and Gaul. Again he sent back all in whom he saw signs of hesitation. With a considerably diminished army he passed the Pyrenees at Bellegarde and encamped at Iliberris (Elne). Some Gallic tribes, alarmed at his advance, had assembled in the neighbourhood, but he soon convinced they chiefs and persuaded them that he meant them no mischief. So he continued his march without molestation to the Rhone.

Meanwhile the Romans had done little or nothing to check their enemy. At last the consul, Publius Cornelius Scipio, arrived at Massilia (Marseilles), and was surprised to find that Hannibal was about to cross the Rhone. But he was too late to oppose the passage, and Hannibal crossed the river probably at some point near the village of Roquevaure. He then followed its course, marching up its left bank to its junction with the Isere at Valence, and entered what was known as the "Island of the Allobroges." It was from thence that he began his famous passage of the Alps.

The narrative of Polybius, though it raises some difficult

questions, has conveyed to most modern students and scholars the impression that Hannibal crossed by the pass of the Little St Bernard. If so, he must have entered Italy by the valley of Aosta. The subject has had a literature of its own devoted to it. The result is that the Little St Bernard Pass may be almost said to have made good its claims to the honour of Hannibal's memorable march. It was familiar to the ancients, and more than once Gauls had passed through it into the plains of Italy. Such high authorities as Arnold, Niebuhr, and Mommsen regard the question as settled in its favour.

Fifteen days in all were occupied in the passage. If the view above indicated is correct, Hannibal at first made his way over Mont du Chat through the Chevelu Pass, then continued his march up the valley of the Isère, and mounted the St Bernard. He must have descended the mountain by the valley of the Donz. Part of his route, that by which he climbed to the summit, was a narrow defile, and there he was threatened by the mountain tribes which appeared on the heights. At the 'white rock,' *la roche blanche*, as it is still called, he halted his infantry, while the cavalry and beasts of burden were making their way during the night to the top of the pass. Next day, the ninth day, he stood with his whole army on the highest point and spoke, it is said, some cheering words to his half-frozen Africans and Spaniards. The descent proved trying and dangerous. From the mountain tribes he had little to fear, it was the mountain slope, covered with recent snow, which caused delay and anxiety. The Italian side of the Alps is considerably steeper than the French side, and a road had to be constructed for the passage of the elephants and horses. This was a work of three days. In three more days they arrived in the valley of Aosta, and were welcomed by the Salassi, a friendly tribe of the Insubrian Gauls. The October of the year 218 B.C. saw the passage of the Alps accomplished and Hannibal with his army encamped in northern Italy.

Thus far he had been successful, but at a tremendous cost. His army was shrank to a force of 30,000 infantry and 6000 cavalry,—the former being composed of Libyans and Spaniards in about the proportion of three to two, and the latter being chiefly Numidians, and admirably efficient.

It was now five months since he had set out from New Carthage. His men of course sorely needed rest, and thus they had for a brief space amid the friendly tribes of Cisalpine Gaul. One tribe indeed, the Taurini, was hostile, but he soon captured their chief city, thus overawing the remaining tribes in the upper valley of the Po. It was now high time for the Romans to exert themselves. Scipio after quitting Massilia, whence he had sent on his army into Spain, had hurried back to Italy, and on reaching Placentia took command of the Roman army quartered there. He was indeed numerically weaker than Hannibal, and was deficient in cavalry. Still he advanced up the Po to meet him, and on the Ticino, somewhere, it would seem, near Vercelli, was fought the first engagement of the Second Punic War. It was a cavalry action, and the inferiority of the Romans in this arm was decisively proved. They were driven back with heavy loss, and Scipio himself was severely wounded, being rescued, it is said, by his son, a lad of seventeen, who subsequently became as famous as Hannibal himself, and had the good fortune to be his conqueror. He has gone down to posterity as Scipio Africanus. The defeated general fell back to the walls of Placentia. The Trebia, a southern tributary of the Po, was between him and the enemy, and he was soon joined by the other consul, Sempronius. Their united armies numbered not less than 40,000 men. Sempronius was for instantly giving battle, Scipio was still disabled by his wound

Sempronius had his way, and on a bitterly cold December day the Romans plunged into the swollen waters of the Trebia in the face of a sleet storm and a cutting wind. They fought well, but when taken in flank by Hannibal's brother Mago, who was lying in ambush amid brambles and bushes in a watercourse, they broke and fled in utter rout.

This decisive victory gave nearly all northern Italy to Hannibal. He let his troops rest during the winter, and added to them a number of Gauls. Early in the spring of 217 B.C. he decided to cross the Apennines and to penetrate into the heart of Italy. The route which he took brought him into the marshy lowlands of the Arno near Luca and Pisa, and here he and his men had to wade through water for four days. Many of them perished miserably, and Hannibal himself lost an eye from ophthalmia. At last he encamped at Fiesole on high ground. The two consuls Flaminius and Servilius were, with their armies, respectively at Arezzo and Rimini. Flaminius was an impetuous man, and eager to win the glory of settling the war once for all. Hannibal, quitting the valley of the upper Arno, marched past him towards Perugia, ravaging the country and so provoking the Roman general to pursue him. The road from Cortona to Perugia skirts the northern shore of Lake Trasimene, and into this road, which is run by a mountain defile, the Roman consuls suddenly entered. They were caught in a trap. Hannibal had posted his light troops on the hills on either side, while he himself blocked the outlet near Passagnano with the best of his infantry. As soon as the Romans were in the pass they were assailed on all sides, and the battle soon became a mere massacre. The Roman army was in fact destroyed, and Flaminius was among the slain. We might suppose that Hannibal would have now done well to have marched straight on Rome, and thus the Romans expected. But he may well have thought that it would be better to wait the chance of insurrection among the Italian communities. So he marched through Umbria, and again crossed the Apennines into Picenum. He then marched southwards along the coast into Apulia and encamped at Arpi. Meanwhile the Romans had made the famous Fabius Maximus their dictator. After levying an army of four legions, Fabius marched in pursuit of the enemy having first effected a junction with the army under Servilius at Rimini.

From the first Fabius had decided on the policy which earned for him the name of the *Cunctator*, the Delayer. He dogged his enemy's steps, but would never risk an engagement. The richest districts of southern Italy were laid waste under his very eyes. But he could not be provoked into any rash movement. Once indeed it seemed as if Hannibal was himself entangled. He had been ravaging Campania, and was on the point of retreating into Samnium, when Fabius posted a force at the head of the pass which afforded the only available means for his retreat. Hannibal is said to have driven a multitude of oxen with lighted faggots on their horns up the hills overlooking the road, so as to give the impression that he and his army were retreating over the heights. Fabius's detachment quitted its position to check the supposed movement, and thus gave Hannibal an opportunity of escaping through the pass. The tactics of Fabius disgusted his men, and when he had to leave them for a time, he found on his return that his master of the horse, Minucius, on the strength of a small success won in his absence, was eager to bring on a general engagement. Fabius gave him a part of the army, with which Minucius ventured on an attack. He was on the brink of destruction when he was rescued by the dictator's timely interposition. After this Hannibal went into winter quarters at Geronium in the north of Apulia.

In the spring of the next year, 216 B.C., he moved south and pounced on Canusae, where the Roman supplies were stored in great abundance. The town is about 8 miles from the mouth of the Aufidus and about 8 from Canosa. The Romans were now again eager to strike a decisive blow. So a vast army was raised by the consuls of the year, *Emilius Paulus* and *Tiberius Vario*, numbering 80,000 infantry and 6000 cavalry. Hannibal's army was probably far inferior numerically. The consuls on arriving in Apulia made *Canusium* (Canosa) their headquarters. For some few days the armies faced each other on the banks of the Aufidus. There were some preliminary manoeuvres and skirmishes, till at last *Vario*, when it came to his turn to command, determined to fight. Both armies crossed the river, and Hannibal's men were drawn up within a loop which it forms near *Canusae*. On either flank he stationed a strong body of his veteran infantry. His other infantry, ranged in the centre in a crescent form, was soon driven in by the Roman legions, which had advanced to the attack in very deep formation. But meanwhile Hannibal's cavalry had put the Roman horse to rout, and had fallen on their rear. The Roman columns were now attacked also on either flank by the Carthaginian infantry. Pressed into a dense mass they were cut down without the possibility of resistance. The carnage is said to have been prolonged for eight hours. The Roman army was all but utterly destroyed. The consul *Emilius Paulus*, nearly all the officers, and eighty senators, perished in the slaughter. *Vario* undisturbed escaped with a few horsemen to *Venusia*. The remainder were slain or made prisoners. It was at a comparatively small cost to himself that Hannibal won this great victory.

It might well be thought that such a victory would prove decisive, and that it must have been had Hannibal instantly pushed on to Rome. But he had probably good reasons for not doing so. He was, it must be remembered, as much as 200 miles from Rome; he would have had to march through still hostile populations, and by the time he would have arrived, he must have known that the first panic would have abated, and that the notion of carrying the city by a coup d'état was simply preposterous. What he counted on was the dissolution of the Italian confederacy, and a widespread revolt throughout Italy. Not was he altogether deceived. The disaster of Canusae shook the loyalty of the Italian peoples. Rome was deserted by most of Apulia and Samnium, and almost wholly by the Lucanians and Bruttians. She retained indeed some strong fortresses, as *Ostia*, *Fregellæ*, *Casertum*, *Beneventum*, *Venusia*, and these enabled her armies to maintain their ground. But *Capua*, in Campania, the richest and most powerful city in Italy after Rome itself, was lost to her. Thence Hannibal made his way from Canusae, and there he went into winter quarters, which were perhaps too comfortable and luxurious. But the story that his men became utterly demoralized is absurd. They proved in the subsequent years of the war that they could move rapidly and fight bravely. We may indeed well suppose that by this time many of his veteran Spaniards and Africans had been replaced by native Italian soldiers. It is, however, clear that he still had a fine army. It is true indeed that after Canusae his star seems rather to decline, but the explanation of this is that the Romans again reverted to the steady cautious tactics which they had learnt under *Fabius*. They too were for the most part well officered. The ablest of their generals was *Marcellus*. Yet even he never beat his antagonist in anything like a pitched battle. The Romans after Canusae made prodigious efforts. They sent three armies into the field, to watch and to check the enemy's movements. They kept themselves in strongly entrenched camps near fortresses which Hannibal had not the means

of taking. Some indeed he did capture, as *Nuceria*, *Acerra*, and *Casertum* in Campania. At *Canusae*, *Neapolis*, and *Nola* he was foiled. The two years after Canusae, 215 and 214 B.C., passed without much being achieved on either side. Hannibal was vaguely hoping for reinforcements from Carthage, and for the aid of *Philip*, king of Macedonia.

Next year, 213 B.C., he gained a considerable success. *Tarentum* surrendered, and so did *Metapontum* and *Thurii*. At *Tarentum* indeed the Roman garrison still clung to the citadel, and Hannibal could not dislodge it. From Carthage he had received a reinforcement of some elephants and of 4000 Numidian cavalry, but this did not enable him to resume the offensive with much effect. Meanwhile *Capua*, besieged by two consular armies, seemed doomed to fall again into Roman hands. One of Hannibal's subalterns, *Hanno*, was defeated in the attempt to retake the place. Hannibal himself hurried to its aid, but he could not bring the Romans to a battle, though he did temporarily raise the siege. The year 212 B.C. was one of mingled success and disaster for Rome. *Syracuse* that year did surrender to *Marcellus*, and Carthage seemed to have quite lost Sicily. Here was an important gain for Rome. But in Spain the two brother Scipios had been cut off by *Hasdrubal*, who could now cross into Gaul and advance on Italy. And in Italy there had been some serious reverses. It would appear that there were actually six Roman armies in the field against Hannibal. One of these under *Fulvius* he destroyed in Apulia; another, made up of enfranchised slaves under *Gracchus*—a proof this of the extremity to which Rome was reduced—he put to rout; *Gracchus* himself perishing in an ambuscade.

By the spring of 211 B.C. the Romans were besieging *Capua* with three armies. It was clear that the city must fall, unless Hannibal could come to its rescue. He made the attempt indeed, but he could not break the hostile lines, so strongly were they entrenched. Then he conceived the idea of drawing them off by menacing Rome itself. Now for the first time he marched through Latium and made it taste all the horrors of war. At last he encamped 5 miles from Rome on the Anio. But the Romans did not lose their presence of mind, or even relinquish the siege of *Capua*; they simply recalled *Fulvius* with one of the armies. There were two legions within the city, and Hannibal probably never meditated a serious assault. He ravaged the country up to the walls, but he did nothing more. Through Samnium he again marched into Apulia and thence into Bruttium, where he unsuccessfully attacked *Rhegium* and the citadel of *Tarentum*. *Capua* meanwhile was forced to surrender. This greatly discouraged Hannibal's Italian allies. *Clacellus* too had come back from Sicily after his capture of *Syracuse*. Altogether the year 211 B.C. was a very unpromising one for Hannibal. Next year, 210 B.C., however, he partly recovered lost ground by completely defeating the Roman prætor *Cneius Fulvius* at *Herdonia*, the modern *Ordona*, in Apulia. But he could not follow up this success, and his evident weakness led to the speedy return of Samnium and Lucania to the Roman confederacy. The following year saw *Tarentum* slip from his grasp. But he soon had his revenge. Next year the two consuls, *Crispinus* and *Marcellus*, were both cut off and slain by the Numidian cavalry in the neighbourhood of *Venusia*. Another disaster soon followed. A Roman army was besieging *Locri* in the extreme south. It was routed and almost destroyed by Hannibal. Thus at the close of the year 208 B.C. the struggle was clearly by no means decided.

Rome had been making immense efforts. We hear of her having twenty-three legions under arms, and possibly the total number of her armies may have reached 200,000 men. The patriotic spirit of her citizens was still at the highest. But her finances were in a deplorable plight, and

corn had risen to an almost famine price. The country round must have been woefully wasted, and multitudes reduced to beggary. One thing indeed the Romans had had to console them during these trying years. The Latin communities in Etruria and Latium had stood by them with wonderful fidelity. This had been their salvation. But now in the years 209 and 208 B.C. came signs of discontent and wavering. Of the Latin colonies several declared that they could no longer furnish contingents or contributions. There were rumours too of a disloyal movement in Etruria. But, worst of all, there came news in the autumn of 203 B.C. that Hasdrubal had crossed the Pyrenees. By next summer he would have passed the Alps. Should the two brothers unite their forces, Rome's fate, it could hardly be doubted, would be sealed. She was now in far greater jeopardy than she was even after the disastrous day of Cannæ.

The year 207 was thus a very anxious one. Claudius Nero and Marcus Livius were the consuls. The first was to watch Hannibal in Apulia, the other was to encounter Hasdrubal in Cisalpine Gaul. Livius retreated before the new invader, and let him reach Sena in Umbria, to the south of the river Metaurus, without opposition. Thence Hasdrubal sent despatches to his brother, who was at Canusium in Apulia. The plan was that they should join their armies at Venusia on the Flaminian road, between 80 and 86 miles from Rome. Unluckily for the two brothers the despatches fell into the hands of Nero. His resolution was formed in a moment. Leaving the bulk of his army in its camp, he hurried northwards with 7000 of his best troops, and after a rapid march of 200 miles he joined Livius. The two generals faced Hasdrubal to a battle. The Carthaginian was utterly defeated, and he was himself slain. Nero returned with all speed to his army, and informed Hannibal of the defeat and death of his brother by having the head of Hasdrubal hung into his camp. With that sight all hope must have died in Hannibal's heart. The battle of the Metaurus was indeed one of the decisive battles of the world. It decided the Second Punic War. From that time, for four more years, Hannibal could but stand on the defensive in the southernmost corner of the Italian peninsula. But even to the last no Roman general dared to close with him. Never in a single battle, as Polybius says, was he beaten while in Italy. Before quitting the country, he left a memorial of his wonderful achievements. In the temple of Juno on the Læmian promontory, near Crotona, he inscribed on brazen tablets in Punic and in Greek an account of his expedition and his campaigns. Polybius saw the inscription and doubtless availed himself of it for his history. For fifteen years Hannibal had maintained himself in Italy, ravaging it from end to end, and inflicting on the Romans according to their own calculation a total loss of 300,000 men. Now all was clearly over. After Nero's victory the Romans could afford to wait the course of events. Scipio had been victorious in Spain, and early in 204 B.C. he was allowed to cross into Africa. Soon it was clear that he would threaten Carthage more effectively than Hannibal had ever threatened Rome. He received the order of recall at Crotona, and thence embarked for Africa. He landed at the smaller Leptis, on the coast of Tunis, late in the year 203 B.C., and lingered during the winter at Hadrumetum, the modern Sousse. His brother Hasdrubal and Mago had both fallen, and he was now the last of the "lion's brood." Fugitive as he was, his presence roused the Carthaginian spirit. The people would not hear of peace. Hannibal indeed attempted to negotiate, and had an interview with Scipio, but in vain. When he saw that he must fight, he could not have felt any of his old confidence. He had some good troops, but he was numerically inferior to the enemy. Of his veterans

but few could have remained. The armies at last met at Zama, somewhere near the modern Kef. The battle was obstinately contested, and Hannibal's old soldiers died fighting in their ranks. But he never really had a chance of victory. Many of his men were raw mercenaries, and some of them deserted to the enemy. His army was utterly discomfited, and indeed annihilated. The defeat was not discreditable to him, but it was decisive. With a handful of men he escaped to Hadrumetum, and in the year 202 B.C. the Second Punic war, more properly, the Hannibalian War was at an end.

He was still only in his forty-fourth year. He soon showed that he could be a statesman as well as a soldier. Peace having been concluded, he was appointed chief magistrate of the state. The office had become rather insignificant, but Hannibal restored its power and authority. The oligarchy, always jealous of him, had even charged him with having betrayed the interests of his country while in Italy, and neglected to take Rome when he might have done so. The dishonesty and incompetence of these men had brought the finances of Carthage into grievous disorder. So effectively did Hannibal reform abuses that the heavy tribute imposed by Rome could be paid by instalments without additional and extraordinary taxation. Carthage grew prosperous, and again the Romans trembled. Seven years after the victory of Zama they demanded Hannibal's surrender. They were still in mortal dread of their old enemy. Hannibal did not wish his countrymen to disgrace themselves, and he therefore at once became an exile. First he went to Tyre, the mother city of Carthage, and thence to Ephesus, where he was honourably received by Antiochus, king of Syria, who was then preparing for war with Rome. Hannibal soon saw that the king's army was no match for the Romans. He advised him to equip a fleet and throw a body of troops on the south of Italy, adding that he would himself take the command. But he could not make much impression on Antiochus, who was a conceited man, quite ignorant of the strength of Rome. The story was told that, pointing to the great army he had assembled at Ephesus, he asked Hannibal if he did not think that these were enough for the Romans. Hannibal's reply was, "Yes, enough for the Romans, however greedy they may be." The great army in which Antiochus had trusted was in 190 B.C. routed by Scipio at Magnesia near Smyrna. Again Rome demanded the surrender of Hannibal.

The end was now at hand. From the court of Antiochus Hannibal fled to Crete, but he soon went back to Asia, and sought refuge with Ptolemy, king of Bithynia. Once more the Romans were determined to hunt out the old man, and they sent Flaminius to wrest on his surrender. Ptolemy was but a poor paltry prince, and he promptly complied. Hannibal did not choose to fall into his enemies' hands at Libyssa, on the eastern shore of the Sea of Marmora, he took poison, which, it was said, he had long carried about with him in a ring. The precise year of his death was a matter of controversy. If, as Livy seems to imply, it was 183 B.C., he died in the same year as his great and victorious antagonist, Scipio Africanus.

As to the transcendent military genius of Hannibal there cannot be two opinions. The man who for fifteen years could hold his ground in a hostile country against several powerful armies and a succession of able generals must have been a commander and a tactician of supreme capacity. Wonderful as his achievements were, we must marvel the more when we take into account the guiding support he received from Carthage. As his veterans melted away, he had to organize fresh levies on the spot. We never hear of a mutiny in his army, composed though it was of Africans, Spaniards and Gauls. He who could throw a spell

HANOVER (German, *Hannover*), formerly an independent kingdom, but since 1866 a province of Prussia, lies between 51° 18' and 53° 53' N lat and 6° 43' and 11° 46' E long., and is bounded on the N. by the North Sea, N.E. by Holstein, Hamburg, and Mecklenburg, E. and S.E. by Prussian Saxony and the duchy of Brunswick, S.W. by Hesse-Cassel and Westphalia, and W. by Holland. These boundaries include the grand-duchy of Oldenburg, which stretches southward from the North Sea nearly to the southern boundary of Hanover. A small portion of the province in the south is separated from Hanover proper by the interposition of a part of Brunswick. The area of the province extends to 14,518 English square miles.

Physical Features.—The greater part of Hanover is embraced in that extensive plain which, commencing on the shores of the North Sea, terminates on the frontiers of Russia. The most fruitful districts are on the banks of the Elbe and near the North Sea, where, as in Holland, rich meadows are preserved from being immersed in water by broad dykes and deep ditches, constructed and kept in repair at great expense. It is only the southern portion that is mountainous, the district of Klausthal, containing the Harz, is wholly so, as well as some parts near Göttingen, and in the district of Hildesheim. The Harz mountains are not a part of any chain, but rise from a plain in an isolated group, the highest points of which are nearly in the centre (see Harz). They are covered with extensive forests. On their lower slopes the trees are of the deciduous kinds, but pines alone are found on the summits.

The whole of Hanover dips towards the north, and the rivers consequently flow in that direction. The Elbe, which forms the boundary on the N.E., receives the following tributaries—*the Ohre*, which rises in the district of Lüneburg, the *Aland* and the *Jetze*, which come out of the province of Saxony, and are navigable in their lower course, the *Ilmenau*, which becomes navigable at Lüneburg, the *Este*, navigable to Brehelnde, the *Luh*, navigable to Hornburg, the *Schweinge*, by which vessels reach Stade, the *Oste*, navigable to Kückshausen, and the *Medem*, which runs through the Hachin-lund, and admits large vessels up to Ottendorf. The *Weser* enters Hanover at Münden, being there formed by the junction of the *Fulda* and the *Veres*. It is navigable for barges from the spot at which its name commences, and it receives the *Hemel*, the *Alte*, the *Oerte*, the *Leine*, the *Böhme*, the *Eyther*, the *Wumme*, which in the lower part of its course takes the name of *Lesum*, the *Geeste*, and the *Hunte*,—all of them purely Hanoverian rivers. The *Emm* rises in the province of Westphalia, and after entering Hanover receives the waters of the *Aa*, the *Emse*, the *Elbe*, and the *Leda*, it falls into the *Dollart* near Emden, which is the principal seaport in the kingdom. It is navigable for flat-bottomed vessels from Rhina downwards, and for sea-going ships from Halte and Weene. The *Veicht*, a river of short course, rises in the province of Westphalia, and falls into the *Zuyder Zee*. A navigable canal from the *Veicht* to *Munster* connects that city with the *Zuyder Zee*. Navigable canals connect the various river systems.

The principal lakes are the *Steinhuder Meer*, about 4 miles long and 2 broad, and 20 fathoms deep, on the borders of Schaumburg-Lippe, the *Dummersee*, on the borders of Oldenburg, about 12 miles in extent, the lake of *Bedarksee*, and some others in the meadows of the north, the *Seeburger See* near Dudenstadt, and the *Odersteich*, in the Harz, 2100 feet above the level of the sea.

Climate.—The climate in the low-lying districts near the coast is moist and foggy, in the plains mild, on the Harz mountains severe and variable. In spring the prevailing

winds blow from the N.E. and E., in summer from the S.W. The mean annual temperature is about 46° Fahr. in the town of Hanover it is higher. The average annual rainfall is about 23.5 inches, but this varies greatly in different districts. In the west the *Hohenrauch*, a thick fog arising from the burning of the moors, is a plague of frequent occurrence.

Agriculture.—Though agriculture constitutes the most important branch of industry in the province, it is still in a very backward state. The greater part of the soil is cultivated in cereals, and that is susceptible of cultivation is still lying waste. Of the entire area of the County 28.2 per cent is arable, 16.6 in meadow or pasture land, 13 per cent in forests, 87.2 per cent in uncultivated moors, heaths, &c., from 17 to 18 per cent is in possession of the state. The best agriculture is to be found in the districts of Hildesheim, Celenberg, Göttingen, and Grubenhagen, on the banks of the *Weser* and *Elbe*, and in *East Prussia*. Of the whole area under cultivation in 1878 there was under wheat 1.9 per cent, 1,70, 10.9, barley, 0.9, oats, 5.7, buckwheat, 1.4, rye, 0.4, potatoes, 2.8, and meadow, 10.4 per cent. The extent of tillage was 2,205,752 acres of a total area of 9,164,446 acres. The total yield in the season 1878 was—wheat, 2,298,543 cwt., rye, 10,545,728 cwt., barley, 1,850,417 cwt., oats, 7,054,889 cwt., buckwheat, 1,150,615 cwt., peas, 238,931 cwt., potatoes, 17,855,490 cwt., hay, 81,238,480 cwt. Rye is generally grown in bread. Flax, in which much of the soil is admirably adapted, is extensively cultivated, and forms an important article of export, chiefly, however, in the form of yarn. Flax, tump, and hops are also among the exports. There were in 1877 805 acres planted with tobacco, the produce of which was 13,907 cwt., valued at £15,180. Of the total area of the province yielding 6,970,480 cwt. of beet root, from which was manufactured in 27 sugar mills with 211 engines of 2133 horse power 581,707 cwt. of raw sugar. Apples, pears, plums, and cherries are the principal kinds of fruit grown. Best *bell-pepper* (*Capersium Peperum*) is raised from the Harz and blackberries (*V. Myrtillus*) from the Lüneburg Heath form an important article of export.

Livestock.—The statistics of 1878 show as in Hanover 101,008 horses, 132 mules, 404 asses, 894,158 head of horned cattle, 1,859,962 sheep (including 511,892 heads of sheep, a very coarse breed), 510,550 pigs, 172,802 goats, and 217,045 beehives. There are principally 1000 of each of the following kinds. The number of sheep was larger before 1867, but the number of horned cattle has increased. Horses are reared in the marshes of *Amuhl* and *Stade*, in Hildesheim and Hanover, the cattle of *Amuhl* (*East Prussia*) are famous for their size and quality. The best sheep belong to the country lying between the *Harz* and the *Elbe*. Large flocks of geese are kept in the moist lowlands, their flesh is suited for domestic consumption during the winter, and their feathers are prepared for sale.

Mining.—Minerals occur in great variety and abundance. The Harz mountains are rich in silver, lead, iron, and copper, coal is found around *Osnabrück*, on the *Deister*, at *Oschatz*, &c., lignite in various places, salt springs of great utility are met with at *Harz* and *Neuhall* near Hanover, and at *Lüneburg*, and petroleum may be obtained south of *Celle*. In the cold regions of the northern lowlands, peat occurs in beds of immense thickness. The mining statistics of the year 1878 give the following quantities: value coal, 301,728 tons (£115,765), lignite, 120,714 tons (£33,734), asphalt, 26,000 tons (£28,000), iron ores, 170,969 tons (£16,000), and 1,511 tons (£25,544), lead ores, 25,000 tons (£133,785), copper ore, 15,738 tons (£45,289), silver ore, 35 cwt. (£1,420), manganese ore, 3070 cwt. (£710), salt from springs, 73,007 tons (£91,499).

Manufactures.—Works for the manufacture of iron, copper, brass, wire, lead, vitriol, and sulphur are carried on to a large extent. About 40,000 persons are employed in these works and in the mines, the yearly revenue from which amounts to £1,800,000. The production of *ladies' dresses* occurs chiefly in 231 towns, lead, 8771 tons, copper, 2550 cwt., silver, 55,882 lb., gold, 171 lb., sulphuric acid, 573 tons, blue vitriol, 788 tons. The iron works are very important. Smelting is carried on in the Harz and near *Osnabrück*, there are extensive foundries and machine factories at Hanover, Lüneburg, Osnabrück, Hameln, Göttingen, Harburg, Osterode, &c., and manufactures of arms at *Heidelberg*, and of cutlery in the towns of the Harz and to the *Solling* Forest. The textile industries are carried on chiefly in 231 towns. Linen yarn and cloth are largely manufactured, especially in the south about *Osnabrück* and Hildesheim, and bleaching is engaged in extensively. Woollen cloths are made to a considerable extent in the south about *Embsay*, Göttingen, and Hameln, and spinning and weaving have their principal seats at *Harz* and *East Prussia*. Glass houses, paper mills, potteries, tile works, and tobacco-pipe works are numerous. Wax is bleached to a considerable extent, and there are numerous tobacco factories, breweries, wine and brandy distilleries. Shipbuilding is an important in-

dutry, especially at Pöpenburg, Emden, Loe, Stade, and Han-
burg, and at Münster, where the bulk

Commerce—Although the carrying trade of Hanover is to a
great extent absorbed by Hamburg and Bremen, the shipping of
the province counts 867 sailing vessels, the larger vessels all
belonging to German owners. Emigration is declining to become a very
important aspect when the extensive labour improvements have
been completed.

Administrative divisions—This province is divided into six hundred and
seventy-two counties, and these again have been subdivided, since the union
with Prussia, into smaller districts. There is a provincial
assembly representing 43 towns and 101 burghs. A court of
appeal for the whole province sits at Götting, and there are 19 superior
courts. To the German parliament (Reichstag) Hanover sends 19
members, to the Prussian house of assembly (Abgeordnetenversammlung) 36.
The debts of the province, contracted before the occupation by
Prussia, amount to 2,220,692.

Population—The census of 1871 gave the population 1,963,618,
1,718,664 belonged to the Evangelical Church, 233,633 were Roman
Catholics, and 12,790 Jews. The urban population numbered

Counties	Extent in English miles	Population, 1st Dec. 1875			Inhabit- ants to the sq mile
		Males	Females	Total	
Hanover	2197.4	215,864	214,696	430,560	196
Hildesheim	1611.7	205,010	209,587	414,597	253
Lüneburg	1611.7	149,765	152,192	301,957	88
Verden	2403.7	154,694	153,615	308,309	123
Osnabrück	2368.6	139,761	138,000	277,761	123
Münster	1181.0	90,810	101,748	202,558	179
	11548.0	1,007,725	1,006,693	2,014,393	159

608,102, and the rural 1,464,597. By the census of 1875 the popu-
lation had reached 2,017,393. There are 111 towns, but only 9 have a
population exceeding 10,000, viz., Hanover, Osnabrück, Hildesheim,
Landsberg, Lüneburg, Celle, Göttingen, and Emden.

Education—Amongst the educational institutions the university of
Göttingen stands first, with an average of 1000 students, and of
400 students. There are besides 18 gymnasiums, a polytechnicum,
11 high-class grammar schools, 11 normal and training schools, a
polytechnic school at Hanover, a school of mines and forestry at
Kassel, seven or eight military schools of six to eight years for
the deaf and dumb, 2 for the blind, and numerous other charitable
institutions.

History—The word Hanover originally applied only to the city,
so called. It was gradually, however, extended to the country of
which Hanover was the capital, and it was officially recognized as
the name of the state when in 1814 the electorate of Lüneburg was
made a kingdom.

In ancient times the country formed part of Saxony, which it
remained independent until the time of Charlemagne, and afterwards
it was included in the duchy of Saxony. After the extinction of
the Billung family, in 1138, the emperor Frederick I. confirmed the
duchy was granted to Lothar of Supplinburg, who in 1125 was
elected emperor. He gave his daughter in marriage to Henry the
Pious, duke of Bavaria, of the ancient house of Guelph, which
thence had its origin. In 1195 Henry the Pious died, and his son
Henry the Lion, after a time of bitter dispute, was installed by
Frederick Barbarossa in his father's great position. In the latter
part of Frederick's reign, in 1180, Henry was deprived of both his
duchies, but was allowed to keep the allodial possessions of his
family, viz., Brunswick and Lüneburg. In 1225 these lands were
yielded by Henry's grandson, Otto Fies, to the emperor Frederick II.,
who granted them to him in fief as a duchy. Otto's two sons
divided their inheritance into two duchies in 1267, and thus was
formed the old Lüneburg and the old Brunswick lines. There was a
fresh division in 1288, whereby were established the Verden and
Lüneburg lines of Brunswick. From 1527 Lüneburg was under
the sole government of Duke Ernest the Confessor, who was an
ardent adherent of Luther, and so persistently laboured to promote
the Reformation in his duchy that it has been named the "Protestant
cradle" ever since. He died in the same year as his friend Luther,
1546, and from him descended the younger lines of Brunswick
and Lüneburg, or of Brunswick-Wolfenbüttel and Brunswick-Lüne-
burg. In 1684 Duke Frederick Ulrich of Brunswick-Wolfen-
büttel, suddenly died childless, and his duchy was inherited by
Augustus the younger, the descendant of Ernest's eldest son Henry,
and Brunswick has remained in the hands of this dynasty till the
present day. Maximilian had been elected king of the Romans by
the younger son of Ernest the Confessor, and when he died in
1688 he left seven sons, of whom four, Ernest, Christian, Augustus
the elder, and Frederick, one after the other, became rulers of the
land. Frederick III. has been dead since 1688, and in 1688, the
year in which the Thirty Years' War was brought to a close. The

only one of the seven brothers who married was George, to whom
was granted as a requital duchy a part of Lüneburg called Calen-
berg, of which he made Hanover the capital, Celle being the capital
of Lüneburg. He married that his eldest son should be allowed
to inherit that Calenberg, the duchy of Lüneburg, and the
duchy not chosen by his brother, and that the remaining sons
should be content without having territory to govern. The result
of this settlement was that his eldest son, Christian Louis, chose
Lüneburg, while he ruled till his death in 1665. His second son,
George Louis, who he ruled till his death in 1699, chose Hanover.
The second son, ruled over Calenberg till 1685, when he transferred
himself to Lüneburg, which he governed till 1705. On his going
to Lüneburg, the third brother, John Frederick, became duke of
Cumbria, in which position he was succeeded by his eldest son,
Augustus, the fourth brother, who married Sophia the grand-
daughter of James I. of England. Ernest Augustus was an
exceedingly ambitious prince, and in order to increase the power
of his country introduced in 1687 the law of primogeniture. He
died in 1699, in consequence of a vast amount of negotiation and
intrigue, he managed to secure for himself and his successors the
electoral title. He died in 1699, and was succeeded by his son
George Louis, who, having married his cousin Sophia Dorothea,
the daughter of George William of Calenberg, finally united the
two duchies on the death of the latter prince. In 1714 George
Louis, the elector of Lüneburg, ascended the throne of Great
Britain as George I.

After this time, until the death of William IV., Lüneburg
remained the same sovereign as Great Britain, and this per-
sonal union of the two countries was not dissolved until the death
for both George II., as the ally of Frederick the Great in the
Seven Years' War, joined the struggle in the capacity both of
elector and king, and while George III. was on the throne there
was hardly a phase of the foreign policy of England in which
Hanover was not reflected. In 1803, when the Hanoverian troops
captulated at Bülten, the country was invaded by a French
corps, which it had to maintain at a heavy cost. The Prussians
secured temporary possession of Hanover in Napoleon's 1806,
but in 1807 a part of it was annexed to the kingdom of Westphalia,
to which the remaining portion was added in 1810. The people
never acquiesced in French predominance, and when the first
French emperor, Napoleon, came they welcomed him with enthusiasm,
with which they flung themselves into it. At the congress
of Vienna in 1815 it was demanded in the name of the elector
(King George III.) that the electorate should be reconstituted as
a kingdom, and not only was the demand admitted, but the new
kingdom received considerable concessions of territory.

Partly through the influence of the French, partly in consequence
of the general progress of ideas, Hanover was not, like many other
parts of Germany, penetrated by a desire for freedom, and such had
been the suffragance of the people, willingly borne for their sovereign
and country, that they felt they had a right to be treated in a con-
siderate and generous spirit. Their wishes were, however, disre-
garded.

Count Münster, who virtually ruled the country from
London, drew up a constitution which came into force in 1810. It
was thoroughly reactionary in tendency, and the more so inas-
much as it was the most completely despotic constitution that
the ruling class. Not until 1831, when there were several popular
revolutions of so serious a nature that Count Münster resigned, was it
deemed necessary to make important concessions, and even then
the concessions which the elector asked for were not granted, but
merely a liberal law by William IV. before he sanctioned it in 1833.

As the law of Hanover prevented a woman from mounting the
throne, Ernest Augustus, duke of Cumberland, became king after
the death of William IV. in 1837. He proved to be a harsh and
narrow minded despot. In 1837 he arbitrarily abolished the con-
stitution of 1833, and when seven professors of the university of
Göttingen protested against the act, he ordered them to be expelled
of their chairs, and three of the most distinguished—Geyser,
Jacob Grimm, and Dahlmann—were banished from the country.
The people were profoundly stirred, and it was hoped that the
obligations imposed by the constitution which had been wrung from
him. The comparatively liberal ministry which had been appointed
in the moment of danger was dismissed in 1850, and probably only
the death of the king in 1851 prevented him from engaging in as
serious a course as ever with the people. His son, King George
V., in 1849, when the Frankfurt diet failed to establish the
unity of Germany, he joined the kings of Prussia and Saxony in
forming what was called "the three kings' alliance," but he soon
was forced to see that this conception, as it concerned himself, was
the thoroughly conservative policy of Austria.

Ernest Augustus was succeeded by his blind son, George V. Personally King George was an amiable disposition, but he shared his father's extravagant conceptions of royal rights, and at once appointed a ministry whose aim was to get rid of the inconvenient constitution of 1848. The second chamber, however, resisted its designs so exceptionally that in 1853 the more reactionary ministers had to resign, and in 1858 even the modified cabinet was completely defeated. The king then created a Government which advised him to appeal to the confederate diet. This was done, and in 1858 the diet proclaimed the constitution of 1848 to be invalid. That a more easy triumph might be secured, the states assembly was dissolved, and a ministry was formed which boldly restored the nominal constitution of 1848. The Government spent no effort to obtain an overruling majority, but, as it still encountered some resistance in the new parliament, fresh elections were ordered, and in 1857 it had the satisfaction of meeting as pliant a body of deputies as the king himself could wish. The people, however, were not in sympathy with their nominal representatives, and gave many proofs of their discontent with the arbitrary rule to which they were subjected. In 1862, when an attempt was made to impose upon the schools the use of a catechism of the 17th century, the popular feeling was so decisively expressed that the king was compelled to dismiss his ministers. The new cabinet, which was rather less extravagant, included Herr Windthorst, who had for a short time had a seat in the German diet, and resigned in 1863, and who has since acquired distinction as leader of the Ultramontane party in the imperial parliament of Germany. King George could not long submit even to a slight modification of his absolutist notions, and in 1865 entrusted Herr von Bismarck, who had done him faithful service in previous administrations, with the task of bringing together a cabinet to his liking.

Meanwhile, however, dangers had arisen in Germany, compared with which the internal troubles of Hanover were of small account. Herr von Bismarck, who now controlled Prussian policy, was devising methods for the realization of his vast schemes; and it became increasingly clear, after the Schleswig-Holstein war, that the independent states of Germany would soon have to accept finally the lead either of Prussia or of Austria. Before the outbreak of that conflict Hanover and Saxony had despatched troops to Holstein for the purpose of executing the will of the house. Although the federal army was driven back by Prussia, Hanover seemed for a time to be favourable to her rather than to Austria; but in reality the sympathy of the court was altogether with the latter power. On the 14th of June 1866, in regard to the decisive question whether the federal army should be mobilized, Hanover voted in the confederate diet with Austria; and by doing so she irrevocably declared on which side she would range herself in the approaching struggle. In consequence of this vote Prussia addressed an ultimatum to Hanover on the 16th of June, requiring her to maintain unarmoured neutrality and to accept the scheme for the reform of the confederation which the Prussian plenipotentiary had submitted to the diet before retiring from it. As Hanover rejected these demands, Prussian troops at once crossed the frontier; and on the 17th of June they were in possession of the capital. On the 27th a battle was fought at Langensalz, in which the Hanoverians were victorious; but they could make no use of their victory, and were soon compelled to capitulate. At the conclusion of the war, by the treaty of Prague, Hanover, with Hesse, Nassau, and Frankfurt, was annexed to Prussia. King George advanced from Hildesheim, near Vienna, a protest to the European cabinets, but it was disregarded; and on the 24 of October 1866, his dominions were formally taken possession of, and in the following year the population were subjected to the Prussian constitution. In 1876 George V. died at Hildesheim, but his son, Ernest Augustus, duke of Cumberland, maintains his right to the crown; and there is still a party in Hanover which expresses itself favourably to him. The names of the population, however, whether originally willing to be annexed to Prussia or not, have submitted to the inevitable, and there is evidence that they are gradually becoming loyal subjects of the Prussian king.

HANOVER, the capital, is situated in the south of the above province, on a sandy but fertile plain on the river Leine, which here receives the Ilme, and is from this point navigable to the Weser. It is 38 miles W. by N. of Brunswick by rail, 157 miles W. of Berlin, 73 S.E. of Bremen, and 107 S. of Hamburg. The Leine flows through the town, having the old town on its right bank, and the Calenberg new town between its left bank and the Ilme. The old town is irregularly built, with narrow streets and old-fashioned houses; while the new town has wide streets, handsome buildings, and beautiful squares. Of the latter the most remarkable are—the square at the railway terminus, with an equestrian statue of King Ernest

Augustus in bronze; the triangular theatre square; George Square, with the statue of Schiller; Waterloo Square, with a column 90 feet high, surmounted by Victory, and having inscribed on it the names of 800 Hanoverians who fell at Waterloo. In the gardens near the square an open rotunda has been erected enclosing a marble bust of Leibnitz, and near it a monument of General Alten, commander of the Hanoverian troops at Waterloo. The town has numerous churches; in the chapel of the palace are preserved the relics of saints which Henry Lion brought from Palestine. The royal palace—built 1636–1640, rebuilt 1837—contains a picture gallery and collection of natural curiosities, and the palace of Ernest Augustus is remarkable for its historic collections, especially the famous Weifen museum. The other principal public buildings are the record office, containing a library of 150,000 volumes; the town-hall, built in the 15th century; the theatre, the museum, the aquarium, the handsome railway terminus, and the exchange. Hanover has a number of colleges and schools, and is the seat of several learned societies. During the last ten years the town has become the seat of various new industries and of an increasing trade. It is connected by rail

with Berlin, Harburg, Bremen, Hameln, Cologne, Altenbeken, and Cassel; and the annual fairs for cloth, leather, yarns, linen, wool, &c., are frequented by large numbers of buyers. There are several banks and a chamber of commerce. Almost every industry is at present represented, whilst in former times the inhabitants derived their chief support from the presence of the court and the nobility. The town possesses large cotton-mills, iron-foundries, and machine factories, numerous tobacco manufactories, breweries, distilleries, &c. Hanover was the first German town that was lighted with gas. It is the birthplace of Sir William Herschel the astronomer (1738), of the brothers Schlegel, and of the historian Fichte; and the philosopher Leibnitz died there (1716). The population has increased from 49,909 (including suburbs) in 1859 to 106,677 in 1879 (with the adjoining Linder, 127,576). In the vicinity are the royal palaces of Herrenhausen, the unfinished Wolfenbüschloss (formerly Mont Brillant), and Marienburg, the private property of Queen Marie, all surrounded by gardens.

(P. 1-3 51)

HANSARD, LUKAS (1752-1828), English printer, whose name is familiar in connexion with the parliamentary reports, was born July 5, 1752, in St May's parish, Norwich. Reversely in business compelled his father, a manufacturer there, to apprentice him to Mr Stephen White, printer. Immediately on the expiry of his apprenticeship Hansard sailed for London with only a guinea in his pocket, and obtained there in 1772 a situation as compositor in the office of Mr Hughes, printer to the House of Commons. There his ability and energy commended him so well to his master that in two years' time he was made a printer, and undertook almost the entire conduct of the business, which in 1800 was assigned completely into his hands, through the retirement of Mr Hughes. Among those whose acquaintance Hansard made in the exercise of his profession and retained by his amiable private qualities, were Oms, Burke, and Dr Johnson, while Porson eulogized him as the most accurate printer of Greek. The promptitude and accuracy with which Hansard printed parliamentary papers were often of the greatest service to Government,—notably on one occasion when the proof-sheets of the report of the Secret Committee on the French Revolution were submitted to Pitt twenty-four hours after the draft had left his hands. On this union with Ireland in 1801, the increase of parliamentary printing was so great that Hansard was forced to give up all private printing except when parliament was not sitting. He devised numerous expedients for reducing the expense of publishing the reports, and in 1805, when his workmen struck at a time of great pressure, he and his sons did not scruple themselves to work as compositors, and to instruct the new hands they had procured. Shortly after printing the report of the session that rose in July 1828, Hansard's health, which had been failing, completely gave way, and he died on October 18 of the same year. See the *Gentleman's Magazine* for December 1828.

HANSEATIC LEAGUE. The word "hansa," when we find it first in the Gothic Bible of Ulfila, signifies a military assemblage or troop. From this comes the general sense of union, and especially in the Middle Ages of union for mercantile purposes. A later but less important meaning is that of a tax paid by traders for the right of forming such an union.

The Hansa, the league which ultimately overshadowed all rivals and usurped the name for itself, was no intentional creation, and we can fix no accurate date for its origin. It arose gradually from two elements, the union of German merchants abroad, and the union of German towns at home.

The first impulse to mercantile union came from the dangers of travelling in the early Middle Ages. In those days mariners had neither chart nor compass to guide their course, and were forced to creep timidly along the shore and to avoid as much as possible the open sea. The merchant had also to dread more positive dangers than those of storm and wreck. The coasts of northern Germany harboured numbers of rovers and pirates, who regarded the peaceful trader as their natural prey. To increase their powers of resistance, it was usual for merchants to undertake their voyages in more or less numerous companies. The union thus begun on sea was still further cemented

on land. In those days law was personal and not territorial. The foreign merchant had no share in the law of the land where he sojourned, he brought with him his own law, and administered it as best he could. The legal customs of northern Germany were substantially alike, and this similarity strengthened the bonds of union among the merchants who found themselves for a time settled in a foreign land. Moreover, the state of trade frequently required a long stay, and sometimes a depositing of goods among strangers. This led in time to the acquisition of common possessions abroad, lodging, storehouses, &c. This common depot, or "factory," became the central point of the union of Hansa formed by the merchants. The union soon received a corporate constitution. At its head stood the elders, whose chief functions were to administer justice and to represent the society in its relations to the natives of the country. It was by means of these orderly unions that the German merchants obtained their important privileges, chiefly advantages in trade and taxes, from the people among whom they sojourned.

The most important German mercantile settlements were founded in Wisby, the capital of Gothland, in London, Novgorod, Bergen, and Bruges. Wisby was the central point of the Baltic trade, the other towns represent the four extreme points of North-German commerce. It was not unnatural that the mercantile settlements should exercise great influence on the towns from which they sprang. In those towns the municipal government was wholly in the hands of merchants. There was no feudal aristocracy as in the Italian cities, and the artisan was always jealously excluded from political power. It is obvious therefore that the policy of the town-councils would often be influenced by the exigencies of foreign commerce. But the influence of the foreign factories was not exercised by all in an equal degree. Wisby differed from the other settlements in the fact that the Germans there were not merchants making a temporary visit, but were real settlers living side by side with the native population. Novgorod was a mere colony of the German settlement in Wisby, and never held an independent position. Bergen was comparatively unimportant, and the German "counsellor" in Bruges was not formed until some amount of union had been attained at home. But in the German colony in London the majority of the members were merely passing traders, who remained citizens of their native towns. It was therefore the London Hansa which exercised the greatest influence on the growth of the town league.

In the reign of Edgar we find the "people of the emperor" occupying a prominent position in London trade, and joined in a lasting league. The members of this league came mostly from Cologne, the first German town which obtained great importance both at home and abroad. Its citizens possessed at an early date a guild-hall of their own, and all Germans who wished to trade with England had to join their guild. This soon included merchants from Dortmund, Soest, and Münster, in Westphalia, from Utrecht, Stavert, and Groningen, in the Netherlands, and from Bremen and Hamburg on the North Sea. But when, at the beginning of the 13th century, the rapidly rising town of Lübeck wished to be admitted into the guild, every effort was made to keep her out. The intervention of the emperor Frederick II was powerless to overcome the dread felt by Cologne towards a possible rival to its supremacy. But this obstacle to the extension of the league was soon overcome. In 1260 a charter of Henry III assured protection to all German merchants. A few years later Hamburg and Lübeck were allowed to form their own guilds. The Hansa of Cologne, which had long been the only guild, now sinks to the position of a branch Hansa, and has to endure others with equal privileges. Over all the

branch Hanseas rises the "Hansa Alamannae," first mentioned in 1182.

The opposition to the exclusive pretensions of Cologne was chiefly the work of Lübeck, and with the rise of Lübeck we must connect the second element, the internal political element, which contributed to the formation of the Hansa. The old capitals of German trade, Cologne and Wisby, took their stand on the unions of German merchants abroad. In opposition to them Lübeck found support in home alliances, in its league with Hamburg and with the Wendish towns. The alliance between Lübeck and Hamburg is generally and with some truth given as the origin of the Hanseatic League. It was well fitted to play this part. These two towns commanded the commerce of the North Sea and the Baltic. By taking the land route between them, a merchant could avoid the dangerous passage of the Sound or the Belts, and could evade the Sound dues which were often exacted by the Danish kings. The first alliance between the two towns, for which there is no exact date, had for its object the defence of the roads between them. From that came agreements as to mutual legal security, and thence they advanced to common political action in London and in Flanders.

The league between Lübeck and Hamburg was not the only, and possibly not the first, league among the German towns. But it gradually absorbed all the others. Besides the influence of foreign commercial interests there were other motives which compelled the towns to union. The chief of these was the protection of commercial routes both by sea and land, and the vindication of town independence as opposed to the claims of the landed aristocracy. The first to join this league were the Wendish towns to the east, Wismar, Rostock, Stralsund, &c., which had always been intimately connected with Lübeck, and were united by a common system of law known as the "Lübsches Recht." The Saxon and Westphalian towns had long possessed a league among themselves, they also joined themselves to Lübeck. Lübeck now became the most important town in Germany. It had already surpassed Cologne both in London and Bruges. It soon gained a similar victory over Wisby. At a great convention in which twenty-four towns from Cologne to Revel took part it was decided that appeals from Novgorod which had hitherto been decided at Wisby should henceforth be brought to Lübeck.

In the 14th century the Hansa changes from a union of merchants abroad to a league of towns at home. In 1330 mention is first made of the Hansa towns, where before it had been the Hansa merchants. In 1343 the league is first designated as the Hansa by a foreign prince, Magnus of Norway, and thus acquires a diplomatic position as a united state. In 1356 a statute about merchants' privileges at Bruges is made, not by the German merchants, but by the towns themselves, through their representatives assembled at Bruges. Henceforth the town-league subordinates to itself the mercantile unions, the factories and depôts of the merchants lose their independence, and become the "counters," as they are called, of the Hansa towns.

The league thus formed would scarcely have held long together if displayed any real federal unity but for the pressure of external dangers. The true function of the Hansa, and especially of the Baltic towns, was to conduct the commerce between the east and west of northern Europe. But the geographical position of the Scandinavian countries enabled them to interpose a bar to this commerce. Thus from an early period the Hansa stood in a position of watchful hostility towards those countries. It was the careful maintenance of this watch over the Baltic which gave Lübeck its position in the league, and which gave

the League its political as contrasted with its mercantile character.

The most dangerous of the Scandinavian countries at this time was Denmark. Until the 16th century the southern coast of what is now Sweden was in the hands of the Danes, who were thus enabled to command the important channel of the Sound, and to interfere with the herring fisheries, a great source of wealth to the Hansa merchants. The Danish kings were almost always opposed to German interests, and were especially jealous of the supremacy of German traders in the Baltic. Eric Menved (1286-1319) almost succeeded in making himself master of the southern coast of the Baltic. He captured Rostock and the island of Rugen. Even Lübeck submitted to him, and was for a time practically detached from the empire. Stralsund alone successfully resisted the Danish attack. The league of Wendish towns was for the time wholly broken up, and the growth of the Hansa was arrested, but it was saved from total dissolution by the feuds which distracted Denmark. Eric's successor, Christopher II, an exile from Denmark, fled to the very towns which his predecessor had humbled. After extorting from him numerous privileges, especially the exclusive right to the fisheries on the coast of Schonen, the Hansa towns restored him to his throne, though to only a fraction of his former power. From 1333 to 1340 Denmark was without a king, and a prey to civil wars. Denmark But as it recovered strength again became formidable to the Hansa. Waldemar III (1340-1377) devoted the early part of his reign to the recovery of the lands which Denmark had lost during the recent troubles. To carry out this policy he had to spend large sums of money, and in his straits he determined to enrich himself by the plunder of German commerce. In 1361 he sailed to Gothland, and surprised and captured the town of Wisby. The news of this act reached the representatives of the Hansa as they were assembled at Griefswald. They at once resolved on war, and in 1362 their fleet stormed and captured Copenhagen. But while they were besieging the strong fortress of Helsingborg, Waldemar attacked the defenceless fleet and destroyed it. This defeat was followed by a truce, which recognized the Danish possession of Gothland. Waldemar might easily have turned this truce into an advantageous peace, but his success seems to have inspired him with the hope of crushing German ascendancy in northern Europe. In 1367 a Hanseatic assembly at Stralsund was informed that Waldemar had laid new duties on the fishing stations, and that he had robbed German merchants in the Sound and the Belts. Another war was inevitable, and this time the result was different. Waldemar did not await the arrival of the hostile fleet, but fled in 1368 to Brandenburg. Denmark fell entirely into the hands of the League. In 1370 Waldemar was compelled, as the price of his return to his kingdom, to sign the treaty of Stralsund. By this treaty the Hansa obtained possession for five years of all fortresses on the coast of Schonen, and as compensation for its losses was to receive for fifteen years two-thirds of the Danish revenues. It was also stipulated that henceforth no king should ascend the throne of Denmark without the consent of the Hansa towns, and that their privileges should be expressly confirmed at each coronation. The treaty of Stralsund marks the zenith of the power and prosperity of the Hansa. The emperor Charles IV, who had always looked coldly on independent combinations among his subjects, seems to have been induced to alter his policy, and in 1375 he distinguished Lübeck by a personal visit. The war against Waldemar III seems to have had a great effect in consolidating the Hanseatic League, and in forcing it to adopt a federal constitution. From 1361 we can date the regular meeting of the general assemblies, whose acts (Recesses) have been preserved in the archives

at Lübeck. These assemblies met once a year about mid-summer, usually but not exclusively at Lübeck. They were attended by representatives of the various towns, but no one below the rank of councillor could act as representative. The League always endeavoured to maintain its autocratic character. The assemblies bound themselves with all the details of foreign policy as well as of internal management. The penalty for non-observance of their decrees was expulsion from the League (*Verbanung*). The chief offence which brought this punishment on a town was the admission of democratic tendencies. The struggle between the *atzenas* and the old burgher families, which is so important a feature of European history in the 13th and 14th centuries, necessarily affected the Hanse towns. It was for admitting *atzenas* to the council that Bismarck was expelled from the League in 1375, and was not re-admitted till 1380, when the old constitution was restored.

Besides the central constitution of the Hansa, there are also traces of an internal grouping. At Bingen the German merchants are divided, according as they came from (1) the Wendish and Saxon towns, (2) Westphalia and Prussia, (3) Gothland, Livonia, and Sweden. This division is supposed to refer to a real division of the League, each third being gathered round one of the three chief towns, Lübeck, Cologne, and Wisby. But in later times we find the League divided into four quarters with their respective capitals, — Lübeck, Cologne, Hamburg, and Danzig.

Although, by comparison the documents which have come down to us, we can trace the existence of a fairly definite system of government, yet we must not imagine that this system was carried out with the regularity of a modern constitution. The composition of the League was always fluctuating, and it is impossible to say at any fixed time how many members it contained. The towns lay scattered over a large territory extending from Revel to the Scheldt, and their interests, both territorial and commercial, must have often clashed. It was only in time of danger that the League displayed any real consistency. When the immediate danger was withdrawn, the want of union soon made itself again manifest. It is true that the towns joined the League of their own accord, but when they had joined, they tried to make their position as independent as possible. They never considered themselves bound to send deputies to the general assemblies. When the deputies did appear they usually came late, and after a matter had been discussed they would insist on referring it to the town-council at home, as their own powers were insufficient. The wonder lies, not in the dissensions which sprang up among the towns, but in the fact that for three centuries they did in a manner hold together, and not infrequently sacrificed their individual advantages for the common good.

From the very moment of the treaty of Stalsund, the weakness of a community founded chiefly on commercial interests began to show itself. The eastern Baltic towns, especially those of Prussia, were indignant at the erection of a staple at Lübeck. They desired to trade directly with England and Flanders. To repress this movement Lübeck as the head of the League entered into the closest relations with the Teutonic order. But the evil of these dissensions lay in the fact that they distracted the attention of the Hansa towns from events in Scandinavia. The influence guaranteed to them by the treaty of Stalsund was never exercised, and their supineness allowed Margaret, Waldemar III's daughter, to unite the crowns of the three Scandinavian kingdoms at Calmar in 1397. The accession of a powerful northern state was obviously dangerous to the ascendancy of the Hansa. About the same time their allies, the Teutonic knights, were threatened in a similar manner by the accession of the Jagellon dynasty in Poland. The battle of Tannenberg (1410) and the peace of Thorn

(1411) were clear signs that the Slavonic races were beginning to turn the tables on the German oppressors. At one time it seemed probable that Slavic and Scandinavian would unite in a great anti-German crusade, and that the Hansa and the Teutonic order — the pioneers of German civilization in northern Europe — would fall victims to the alliance. During the 15th century the Hansa towns were frequently compelled to seek safety in arms. Their constant policy was to break up the union of Calmar. In 1428 they sent a large fleet against Eric, Margaret's successor, who wished to add Schleswig and Holstein to his possessions. The accession of two German princes, Christopher of Bavaria and Christian I of Oldenburg, to the Danish crown was due in no slight measure to the evasions of the Hansa. On the whole the League held its own in this century, though not without considerable and increasing difficulty.

But with the 16th century the Hansa begins really to decline. The English and Dutch proved formidable rivals for the commercial supremacy in northern Europe. Henry VII secured in 1489 a treaty from Hans of Denmark, which gave England the right of commerce in the northern seas, and which enabled English merchants to found mercantile establishments in the ports. The herrings no longer came in crowds to the Swedish and Norwegian coasts, where the members of the Hansa had so long held a practical monopoly of the fisheries. The fish market at the time was one of their periodical changes of course, and went to the coasts of Holland. The Dutch were not slow to grasp at the advantage, thus offered to them. Another great blow was dealt to Hansatic commerce by the grand discoveries of the age. Most of the German towns were out of the way of the new commercial routes, and could scarcely hope to hold their own with more favourably situated countries.

Besides these causes of decline, the domestic position of the Hansa towns had altered very much for the worse. While in other countries the power of the feudal nobles had fallen before the rapid rise of the monarchy aided by the sympathy of the commons, in Germany alone the power of the princes had constantly increased, at the expense of both king and people. The Reformation and the consequent secularization of church property in northern Germany only served to strengthen the hands of the lay princes. Such a state of things was fatal to the independence of a town league which had always stood opposed to the lawless independence of the nobles. Gradually most of the towns fell off from the League. Foreign countries triumphed at the fall of their formerly successful rival. In Elizabeth's reign the Hansa merchants in London lost the privileges which they had held since the time of Henry III.

Religious disturbances and the fearful distress of the Thirty Years War completed the work thus begun. The peace of Westphalia restored the form but not the reality of the League. In 1668 the last general assembly was held. Henceforth the name of Hansa towns was kept by Lübeck, Hamburg, and Bremen, but it was to designate their independence, not their union.

HANSEN, PETER ANDREAS (1795-1874), astronomer, was born on December 8, 1795, at Tondern, in the duchy of Schleswig. When a youth he served an apprenticeship to a clock and watchmaker at Flensburg, with whom he remained several years. During this time he exhibited an

intense interest for mathematics and the physical sciences, which was the means of his introduction in 1830 to Schumacher, professor of astronomy at Copenhagen, who, appreciating Hansen's abilities, engaged him to assist in the measurement of an arc of meridian in Holsten. This led to his appointment as assistant to Schumacher at the observatory of Altona, on its foundation in 1833. Hansen's reputation as an excellent mathematician had by this time become generally known, and in 1835 he was selected to succeed Professor Encke as director of the observatory of Seeberg, near Gotha. There he remained for the rest of his life, devoting his talents to the development of the highest branches of mathematical astronomy, with an originality of conception which was acknowledged by the English Royal Astronomical Society on two occasions, by the award of their gold medal for his researches in physical astronomy and his lunar tables. His *Tables de la Lune* appeared in 1857, published at the expense of the British Government, they have been adopted for use in the calculations of the *Nautical Almanac*. In addition to his important volume containing the full details of the formulae explanatory of his lunar theory, Hansen was the author of a large number of miscellaneous astronomical papers, principally relating to the orbits of comets and planets or to perturbational astronomy. In one of these he was the first to point out that Encke's value of the horizontal equatorial solar parallax required to be increased to reconcile the lunar theory with modern observations—an opinion which was subsequently confirmed by Le Verrier from his planetary researches, and by the observations of Mars and the transit of Venus of 1874. Hansen was a foreign member of the Royal Society, and an associate of the Royal Astronomical Society. He died on March 28, 1874, at the age of seventy-eight.

HANSTEEN, CHRISTOPHER (1784–1873), astronomer and physicist, was born at Christiansia, Norway, September 26, 1784. From the cathedral school he went to the university at Copenhagen, where first law and afterwards mathematics formed his main study. In 1806 he taught mathematics in the gymnasium of Frederiksberg, Zealand, and the following year he commenced the inquiries in his favourite branch of science—terrestrial magnetism—which have made his name famous. He took in 1812 the juré of the Danish Royal Academy of Sciences for his reply to a question on the magnetic axes. Appointed lecturer in 1814, he was in 1816 raised to the chair of astronomy and applied mathematics in the university of Christiansia. In 1819 he published his researches on terrestrial magnetism, a work which attracted the notice of the physicists of Europe and particularly of England, where the search for a formula by which the variation of the needle might be found at any given time and place was being actively pursued. The researches were translated into German by P. T. Hansen, under the title *Untersuchungen über den Magnetismus der Erde*, with a supplement containing *Beobachtungen der Abweichung und Neigung des Magnetnadeln*, and an atlas. The rules there framed for the observation of magnetical phenomena have been generally followed. Hansteen hoped by them to accumulate analyses for determining the number and position of the magnetic poles of the earth. In prosecution of his researches he visited London, and also Paris and other Continental cities, and travelled over Finland and the greater part of his own country, and in 1828–30 he undertook, in company with Ermann and Düro, and with the cooperation of Russia, a Government mission to Western Siberia, the chief aim of which was to find the ideal point of the Asiatic pole of magnetism—ten observatories being established in Russia to further the project. The scientific results—magnetic, astronomical, and meteorological—form the bases of many valuable theories. A narrative of the personal adventures

soon appeared (*Reise-Erinnerungen aus Sibirie*, 1854, *Souvenirs d'un voyage en Sibirie*, 1857), but the chief work was not issued till 1863 (*Reisende magnetischer Beobachtungen*, &c.). Shortly after the return of the mission, an observatory was erected in the park of Christiansia (1833), and Hansteen was appointed director. On his representation a magnetic observatory was added in 1839. In 1835–38 his text books on geometry and mechanics were published, and in 1842 he wrote his *Disquisitiones de mutationibus quas patitur momentum axis magnetici*, &c. He also contributed various papers to different scientific journals, especially the *Magasin pour l'enseignement*, of which he became joint editor in 1823. He superintended the trigonometrical and topographical survey of Norway, begun in 1837. He was a member of the Royal Society of London, the French Institute, the American Academy of Arts and Sciences, and the Academies of Berlin and St. Petersburg. In 1861 he retired from active work, but still pursued his studies, his *Observations de l'induction magnétique* and *Sur les variations séculaires du magnétisme* appearing in 1865. Hansteen died at Christiansia, April 16, 1873.

HANUSCH, IGNAZ JOHANN (1812–1869), Bohemian savant and philosopher, was born at Prague on the 28th November, 1812. He received his early education in his native city, and taught for a short time in a boarding school there. At the universities of Prague and Vienna, where he afterwards studied, he directed his attention successively to theology and law, and finally, under the influence of Hegel's writings, to philosophy. After temporarily supplying in 1835 the place of Lichtenfels, professor of philosophy at Vienna, he was next year appointed ordinary professor of philosophy at Lemberg, whence he passed in the same capacity to Olmütz in 1847, and two years later to Prague. There he began a successful course of philosophy in the Czech language, but in 1852 was abruptly suspended from teaching, owing to his leanings towards Slavism. He still, however, retained his full salary, and in 1860 he was nominated director of the imperial university library at Prague, whence he died on the 19th May 1869.

His chief writings, mainly on philosophic and Slavonic subjects, are the following—*Ueber die Slavischen Mythen* (1842), text books in *Logik* (1843), *Ethik* (1860), *Metaphysik* (1846), and *Logik und Psychologie* (1849), *Geschichte der Philosophie von ihrem Ursprunge bis zur Gegenwart* (1850), *Vorlesungen über die Kulturgeschichte des Menschthums* (1840), *Quellenkunde und Bibliographie der böhmisches slavischen Literatur* (1868). Besides these, he published some works in Czech, and published the works of the old Slavonic philosopher, Ritter Thomaz, in 1852.

HANWAY, JONAS (1712–1789), an English traveller and philanthropist, was born at Portsmouth, but he was still a child when the death of his father, a victualler by trade, caused his mother to remove with his family to London. At the age of seventeen the boy was apprenticed to a merchant in Lisbon, and he remained there till he entered business for himself. In 1743, after he had been for some time again in London, he became a partner with Mr. Dingy, a merchant in St. Petersburg, and in this way had his attention turned to the trade between Russia and Persia. Leaving St. Petersburg on the 10th of September 1743, and passing south by Moscow, Zouritan, and Astrakhan, he embarked on the Caspian on November 22d, and arrived at Astrabad on December 18th. In his difficulties began. The town was attacked and captured by a rebel, Mohammed Hassan Beg, his goods were seized, and it was only after great privations that he reached the camp of the Shah Nadir. Obtaining an order for the restoration of his goods he returned to Astrabad, and succeeded in recovering about 85 per cent. of the original value, but he was obliged to retraced his steps, and after a painful journey, during which he was attacked by pirates, detained by sickness, and obliged to perform six weeks' quarantine,

he arrived at St Petersburg July 9, 1780. The autumn of that year he spent travelling in Germany and Holland, and on October 28th he landed in England, where the narrative of his travels published in 1783 soon made him a man of note. The rest of his life was for the most part spent in London, and his leisure was devoted to the advocacy and support of all kinds of useful and benevolent enterprises. In 1763 he was appointed one of the commissioners for victualling the navy, and on his resignation in 1783 he received the whole of his salary as a pension. He died September 5, 1786. Hanway was naturally a healthy and active man, in Russia he was known as the handsome Englishman, but the effects of his travels in Persia rendered him somewhat of a valedictorian. He is popularly known as the first Englishman to carry an umbrella in his native country, thus he posited in usage in spite of all the efforts of the hackney coachmen to hoot or hustle him into conformity. He succeeded in winning down the custom of giving veils, and in his *Journey from Portsmouth to Kensington* he attacked the pernicious habit of tea-drinking, which, however, found an able and ardent defender in Dr Johnson. In 1787 he took an active part in founding the Marine Society, the object of which was to fit out poor boys and men for the navy, he was one of the originators of the Magdalen Hospital, it was due to his continued efforts that the Act of George III was passed for the better treatment of the parish infants, and in 1788 he took up the lamentable case of those little chimney-sweepers whose dangerous occupation is now a thing of the past. The method of solitary confinement for prisoners found in him one of its earliest advocates, and in various other ways he sought to improve the chances of the criminal population. "Every man," was his theory, "is capable of good if properly treated." If doing justice to an offender implies an attempt to reform him by using the proper means, by parity of reasoning the using of improper means is doing injustice." Hanway's writings are of little value except for the sake of the causes which they supported, while effective as pamphlets, they lack both style and method, and are apt to run over into platitudinous moralizing. See Pugh, *Remarkable Occurrences in the Life of Jonas Hanway*, 1787.

HAFARANDA, from *Haaparanta*, "Aspen-shore," a small town of Sweden in the district of Torné, at the northern end of the Gulf of Bothnia, in 65° 51' N lat. It lies about a mile from the mouth of the Torné-Elf, exactly opposite the town of Torné, which has belonged to Russia since 1809. Hafaranda was founded in 1812, and at first bore the name of Carljohansstad or Charles John's Town. It received its municipal constitution in 1842. The inhabitants, who according to the census of 1875 number 914, carry on a brisk trade and engage in ship-building. Since 1859 the town has been the seat of a meteorological station, which is one of the most valuable in Europe, not only because it lies so far north, but also because of its position at the head of the Gulf of Bothnia, and immediately to the south of the line of junction between the permanently open sea and the sea which is frozen during the winter months, or, in other words, in the region where at certain seasons there is an extraordinary crowding together of the isothermal lines.

HABSBURG, or HABSBURGA (originally *Habritsburg*, that is, Hawkcastle), an old German family which has given sovereigns to Germany, Spain, and Austria, takes its name from the old Swiss castle of Habsburg, now in ruins, situated on the river Aar in the canton of Aargau. The first mention of the countship of Habsburg is in a document of 1099, where the name Werner, count of Habsburg, occurs in connexion with the consecration of the monastery of Muri as confirming the grants of the pious foundations

made by his ancestors. This Werner of Habsburg was a nephew of Werner, bishop of Strasbourg, who built the castle of Habsburg about the year 1020. The succession of the family cannot be traced between this period and the time of the emperor Frederick Barbarossa, but in a document whose date is 30th May 1163, Werner II and his son Albert the Rich are mentioned as counts of Habsburg. Thus Albert was by Frederick created landgrave of Upper Alsace, and received the countship of the district of Zurich and the protectorship of the monasteries of Seckingen and Murbach, and on the extinction of the house of Zähringen he also succeeded to a considerable portion of their territories. Albert died in 1199, and was succeeded by his son Rudolf the Old, who, as a reward for placing a large sum of money at the disposal of Frederick II, received from him the countship of Aargau. He held an influential position among the Swabian nobility, and so increased his possessions that they included the territories of the bishops of Strasbourg, Constance, Basel, Cone, Ghent, and Lausanne, and of the abbot of St Gall, in addition to which he also obtained the countship of Frickgau. Rudolf left behind him two sons, Albert the Wise and Rudolf II, who shared the possessions between them, and founded respectively the lines of Hapsburg-Hapsburg and Hapsburg-Laufenburg.—Albert, besides the castle of Hapsburg, holding the lands in Aargau and Alsace, and Rudolf the countships of Klettgau, Rheinfeld, and Laufenburg, and the revenues in the latter. The Laufenburg line was also divided into two branches, the former of which became extinct in 1408 and the latter in 1415. Laufenburg thereupon fell to Austria, and Klettgau, through the marriage of the female heiress of the line, to the counts Sutz, from whom it passed by marriage in 1087 to the house of Schwyzenberg. Albert the Wise of Hapsburg-Hapsburg was married to the countess of Kyburg, who was descended from the dukes of Zähringen, and related to the emperor Frederick II. From this union there was born on the 1st May 1218, Rudolf, the founder of the royal dynasty of Hapsburg. He was elected king of Germany in 1273, and after the defeat and death of Ottokar, king of Bohemia, in 1278, at Marchfeld on the Danube, he annexed to his possessions Austria, Styria, Carinthia, and Carniola. On the death of Rudolf in 1291 Adolf, count of Nassau, was elected his successor to his German crown, but although on the death of Adolf it again reverted to the Hapsburg line in the person of Albert I, it passed on his death to Henry, count of Luverburg, and with the exception of the doubtful period when Frederick, eldest son of Albert, and Lewis, duke of Bavaria, divided the suffrages of the electors and were crowned, the one at Bonn and the other at Aachen, the Hapsburg line remained excluded from its possession till the time of Albert II, who succeeded as king of Bohemia and Hungary in 1437, and Sigismund as king of Bohemia and Hungary in 1438. The greater part of the original lands of the house were gradually lost by the victories of the Eidgenossen, who finally in 1474 obtained Aargau, in which the castle of Habsburg was situated. Philip, son of Maximilian I and of Donna Juana of Spain, ascended the Spanish throne in May 1506, and on his death in September of the same year, he was succeeded by Charles I, who was chosen emperor in 1519, and was thenceforth known as Charles V. In 1521 Charles granted his Austrian possessions to Ferdinand I, who became the head of the Austrian dynasty. The Spanish branch became extinct in 1700 with the death of King Charles II, and the male line of the Austrian branch became extinct with the death of the emperor Charles VI. in 1740, but the Austrian house was continued in the female line by Maria Theresa, who by her marriage with Francis of Lotharinga, chosen emperor in 1745, founded

HARBOURS AND DOCKS

I. HARBOURS.

Plates
VIII.
XII.

ALL harbours may be classed either as havens for the protection of ships during storms, or as ports suited for commercial purposes. Of the first mentioned class, or those which are called harbours of refuge, some are natural and some are artificial.

The designing of harbours constitutes confessedly one of the most difficult branches of civil engineering. In making such a design the engineer, of course, avails himself of the information which is derived from past experience, and endeavours, to the best of his power, to institute a comparison between the given locality and some existing harbour which he supposes to be similarly situated. Perfect identity, however, in the physical peculiarities of different localities seldom if ever exists, and all that can be done in deriving benefit from past experience is to select the harbour which seems most nearly to resemble the proposed work.

In order the better to understand the nature of the difficulties which beset the marine engineer, let us suppose that he is called upon to design works for the accommodation of shipping in a given locality. The questions which immediately press on his attention are—(1) What is the cheapest kind of design that is suitable for the place and efficient for the class of shipping which has to be accommodated? and (2) What are the smallest sizes of materials and thickness of walls that are admissible in its construction? as on these the cost of the work will materially depend. Before considering how far it is possible to answer such questions, let us endeavour to define the varieties of design into which all sorts of harbours may, with propriety, be resolved.

In the first place they may be all classified under two main heads—*viz.* *interior works* and *exterior works*.

The interior works are provided for the accommodation and repair of vessels, while the exterior works may be conveniently enough divided into the following five classes.

Different
classes of
harbours.

1. *Harbours of Refuge and Anchorage Breakwaters.*—These consist of one or more breakwaters, so arranged as to form a safe roadstead, which shall be easily accessible to the largest vessels in all states of the weather and tide. A breakwater forms a barrier either complete or partial to the progress of the waves, and is intended for sheltering the anchorage ground under its lee. It is not used for commercial traffic as are piers or quays, and therefore a parapet is not necessarily required for preventing the waves from breaking over the top, although this may be useful as a protection against the wind.

2. *Deep-water and Tidal Harbours for Commercial Purposes* (fig. 1, a, b).—A harbour for commercial purposes is any arrangement of piers or breakwaters, or of both, which

Fig. 1.

encloses and so tranquillises a sheet of water, that vessels may be moored at the quay walls or wharves which form the inner sides of the piers. Where the coast line lies open to

a very heavy sea it is often found necessary to make a double or compound harbour (fig. 1, b). In such a case the entrance to the inner basin is situated within the elevated area formed by the outer works.

3. *Kanted or Curved Piers* (fig. 1, c).—Where there is a single pier of this kind vessels lie under the lee of the kant or kante, and the sheltered side of the pier is therefore finished as a quay. As the outer end of any such single pier is surrounded by the open sea, it may be convenient to call it a "free end" in contradistinction to the outer end of a close harbour, where the sea room in the fairway is limited to the breadth of the entrance which ought, for sheltering the basin, to be made as narrow as is consistent with the safe passage of vessels. Both extremities of all single insulated breakwaters are of course free ends, as are also the seaward ends of all single breakwaters which are connected with the land.

4. *Straight Piers* (fig. 1, d).—A straight pier generally projects at right angles to the coast line, with a free end at its seaward extremity; and, unless when the wind blows right in upon the shore, a straight pier will always afford some shelter on its lee side.

5. *Quay or Wharf* (fig. 1, e).—A quay wall is usually built parallel to the line of shore. It affords no shelter of any kind, and the only advantage which it possesses is that of enabling vessels to load and unload without their having to "beach," or where the shores are steep, even to take the ground.

It will be observed that all the kinds of piers or harbours just enumerated differ materially from each other in the amount of shelter which they afford, and are suitable for presenting very different degrees of exposure. The first step to be taken, therefore, is to select from the different classes of designs which have been enumerated the one which is best adapted to the physical peculiarities of the situation. The engineer in order to make this selection judiciously must keep in view the essential elements of stability, economy, safety of ingress and egress, and convenient accommodation for the trade of the port. If the place be much exposed, he must therefore arrange the different parts of the work so as to produce a harbour which may be easily taken and left in stormy weather, without endangering the tranquillity of the internal area; for it is the combination of the qualities of an easy and safe entrance and exit, with a good "loose" and a smooth interior, which alone constitutes a good harbour. Lastly, he must fix the width of the piers and height of the parapets.

The local characteristics which at the outset demand our Local consideration are—(1) the geological and other physical peculiarities of the shore; (2) the exposure; (3) the force of the waves due to the exposure; (4) the strength, direction, and range of the tides; (5) the depth of the bay or sea in which the harbour is to be built; (6) the proximity of deep water to the works, or in other words, the slope of the fore-shore; and (7) the angle at which the heaviest waves impinge on the coast line and on the works.

Before considering some of these questions the reader may refer to figs. 2 and 3, on which are marked the technical names of different parts of harbour works.

Generation of Waves.

Mistakes as to the level of the highest tides are sometimes made by drawing too hasty conclusions from the presence of vegetable life. In the Rhetland Islands there may often be seen large blocks of rock (and to these reference will afterwards be made), which during storms have

Level of
place of
section of
water.

been driven over the land at heights much greater than that at which vegetation commences and far above the ordinary run of the surf.

The Level below the surface of low water at which mud
 seeps will be found of very considerable value in judging
 of the exposure of a coast. It may appear unlikely that the
 disturbance of the surface of the sea occasioned by storms
 should be propagated to great depths, but there is no want
 of evidence on this head. Sir G B Airy, the astronomer-
 royal, has shown, on theoretical grounds, that at a depth
 equal to the length of the wave the motion is $\frac{1}{250}$ of
 that at the surface, and mentions that heavy ground swells break
 in a depth of 100 fathoms. Sir J Coode found, from under-
 water examinations made with the diving dress, that the
 shingle of the Chisel Bank was moved during heavy winter
 storms at a depth of 8 fathoms, and Captain E K Calver,
 R.N. has seen waves 6 or 8 feet high change their colour

the sea—to the coasts of Holland, where the waves are much modified. Although it is no doubt true that the flat-bottom vessels of the Dutch are built purposely for resisting a heavy surf, still the fact of their being able to take the open beach in nearly all weathers without any protection from harbours, proves that the waves are very much reduced before they reach the Dutch coast. Mr Hyde Clarke says:—"On the coast of Zealand the Dutch reckoned 8½ feet as the greatest height to which any wave would be thrown."

In comparing an existing harbour with a proposed one, Line of perhaps the most obvious element is what may be termed the *line of maximum exposure*, or, in other words, the line of greatest fetch or reach of open sea, and this can be easily measured from a chart. But though possessed of this information, the engineer still does not know in what ratio the height of the waves increases in relation to any given increase in the line of exposure.

In 1853, in the *Edinburgh New Philosophical Journal*, Mr. Law of Thomas Stevenson stated as the result of experimental observation that the heights of the waves were most nearly "in the ratio of the square roots of their distances from the windward shore," or when h = height of wave in feet, λ = distance in miles, and a a coefficient varying with the strength of the wind, then

The truth of this law has since then been variously tested¹. The accompanying table contains some of the observations made in 1850-52, as well as later observations on the effects of heavy gales which could only be made at long intervals of time —

from the abutment of the bottom after passing the water of 7 or 8 fathoms. Captain Claidman states that waves may excavate the bottom at a depth of 655 feet in that man, of 163 feet in the Mediterranean, and of 132 feet in the English Channel and Adriatic. From these statements it may easily be inferred that in exposed situations mud can not repose near the surface. Applying such a test to the German Ocean, it is found that in Shetland mud lies in from 80 to 90 fathoms below low water, and its level gradually rises till, on the coast of Holland, it is found at a depth of from 18 to 15 fathoms at the mouth of the Elbe. Now, the violence of the waves upon the shores of the German Ocean certainly corresponds with the rise in the level of the mud, these being a gradual decrease as we come from Shetland and the north of Scotland—where, as will be afterwards shown, wonderful energy is displayed by

[illegible]

Some of these earlier results have also been laid down in fig 4, so as to form a storm curve, but since the diagram was made many more observations have been obtained which corroborate the law

The formula $h = 1.5 \sqrt{d}$ is represented by the parabolic curve in the diagram, which indicates pretty nearly the height of waves during heavy gales, at least in seas which do not greatly differ in depth from those where the observations were made. This formula is of course inapplicable where the water is not of sufficient depth to allow the

² It follows from this law that the heights of embankments of rever voirs above the water surface should, *ceteris paribus*, be proportional to the square roots of the lengths of water over which the wind acts

waves to be fully formed, or where it becomes so shallow as to reduce their height after they are formed.

It must be observed that in short fetches, as in narrow lochs or arms of the sea, waves are raised higher during very violent gales than the formula indicates, though it does not appear that such waves go on progressing in height in the same high ratio for any considerable distance

as the maximum effect, and which are due to the line of maximum effective exposure, $\alpha =$ azimuthal angle formed between the direction of pier and the line of exposure, then, when the force is resolved normal to the line of pier,—

$$w = h \sin^2 \alpha,$$

but if the force be again resolved in the direction of the waves themselves, the expression becomes

$$w = h \sin^4 \alpha.$$

It should not, however, be forgotten, in connexion with this subject, that in some cases there are modifying elements to which special attention requires to be given. The waves, for example, when approaching the land obliquely, alter their direction when they get close to the shore, in consequence of the change of depth, and from this cause they approach more nearly at right angles to the general line of the beach, and thus strike with greater force than the line of maximum effective exposure would lead us to expect.

The extraordinary difference between waves which impinge at right angles and others which have even a very slight amount of obliquity has been shown in the most unmistakable manner at the Wick breakwater, where all attempts to make the work stand when exactly at right angles to the waves have hitherto been unsuccessful. It was found by observation that while waves coming from the direction of S by E struck the outer part at normal incidence, they struck the landward end of the same bank at an angle of 81° , giving 9° of obliquity. This small measure of relief was found to make a great difference in the impact upon the wall.

The value of the line of effective exposure varies in certain localities with the geographical configuration of the land, as in Loch Fyne, where the wind seems to alter its direction with the winding of the loch, so that the effective fetch is greater than the width of free water at the place.

On the other hand, where the channel expands, the height of the waves is decreased, as at Crugmore in Mull, where the highest wave observed during the winter of 1853-4 was very much less than the formula indicates.

In a case such as represented in fig. 5, the waves which enter the entrance channel or harbour mouth B, though generated apparently in the fetch AB, are largely due to the fetch CB. For the waves generated in the length CA pass round the point A, and are thereafter subject to the impulse of the wind along the line AB. The waves then which enter the harbour mouth, instead of having their point of genesis at A, really take their origin at C, and their height is due to the fetch CB, though reduced by a deflexion round the point A.

Lateral friction is due to the passage of the end of the lateral wave along the face of a vertical wall, while lateral erosion friction is due to the end of the wave breaking as it passes along and the face of long talus walls or sloping beaches.

Force of Waves

Smanton, in referring to the propriety of using joggles in the masonry of the Eddystone Lighthouse, says, "When we have to do with and to endeavour to control those

Fig. 4

For short reaches and violent squalls, the formula given in column 5 of the foregoing table will be found more suitable, viz. —

$$h = 1.5 \sqrt{d + (3.5 - d)^2}$$

For all ordinary situations the results in the following table will be found sufficient as a general guide.

Table showing approximate Heights of Waves due to lengths of Maximum Fetch by the Formula

Miles	Height	Miles	Height	Miles	Height	Miles	Height
1	3.0	20	7.1	30	9.4	100	17.1
2	3.1	21	7.2	40	9.6	140	17.7
3	3.2	22	7.4	41	9.6	150	18.4
4	4.1	23	7.5	42	9.7	160	19.0
5	4.3	24	7.6	43	9.8	170	19.6
6	4.6	25	7.8	44	9.9	180	20.1
7	4.8	26	7.9	45	10.0	190	20.7
8	5.0	27	8.0	46	10.2	200	21.2
9	5.3	28	8.1	47	10.3	210	21.7
10	5.6	29	8.2	48	10.3	220	22.2
11	5.7	30	8.4	49	10.5	230	22.7
12	5.9	31	8.5	50	10.6	240	23.2

17	6.7	36	9.0	100	15.0	340	25.5
18	6.8	37	9.2	110	15.7	360	26.0
19	7.0	38	9.3	120	16.4		

The Comte de Mearill, in 1725, observed waves 14 foot 10 inches in height where the longest possible fetch is 600 miles. At Wick, with much the same exposure, waves of about 40 feet have been seen to strike the breakwater.

But the highest which are known to have been accurately measured were by Dr Scoresby in the Atlantic, where they attained the height of 43 feet above the hollow. Chailly gives observations of others which were from 60 to 108 feet high, but he does not state how the heights were ascertained.

It does not follow, however, that the line of the maximum exposure is in every case the line of maximum effective force of the waves, for this must depend, not only on the length of fetch, but on the angle of incidence of the waves on the walls of the harbour. What may be termed the line of maximum effective exposure is that which, after being corrected for obliquity of impact, produces the maximum result, and this can only be ascertained from the chart by successive trials.

Let $\alpha =$ the greatest force that can assail the pier, $h =$ height of waves which produce (after being corrected for obliquity) the max-

Fig. 5

powers of nature that are subject to no calculation, I trust it will be deemed prudent not to omit, in such a case, anything that can without difficulty be applied, and that would be likely to add to the security." This statement of our greatest marine engineer indicates the propriety of carefully collecting any facts that may help us to a more accurate estimation of those forces which he regarded as being "subject to no calculation."

At the Bishop Rock Lighthouse, a bell was broken from its attachments at the level of 100 feet above the high water mark during a gale in the winter of 1860, and at Unst, the most northern of the Shetland Islands, broken open a block of 195 tons above the sea. To these facts it may be added that, as proved by the testimony of an eye-witness, a block of 50 tons was moved by the sea at Barrahead, one of the Hebrides. But still more extraordinary efforts have been observed at Whaley in Shetland, where heavy blocks have been quarried, or broken out of their beds *in situ*, on the top of the Boned Skerry at a great elevation above the sea. On the south-east side, about 370 feet from the low water mark, and at a height of 224 feet above its level, there occurs a remarkable bench of angular blocks varying in size from 24 tons downwards, which are huddled together just as one would have expected to find, had they been elevated only a few feet above the high water level. Towards the north-east at the level of 72 feet above the sea, in addition to many smaller blocks which had evidently been recently detached, there was one 24 tons in weight. It presented the appearance of recent detachment, having a fresh unweathered look. Within 20 feet of the spot where it lay, there was a comparatively recently formed void in the rock, which upon examination and comparison by measurement was found to suit exactly the detached block. Here there was a phenomenon so remarkable as almost to stagger belief—a mass of 24 tons still only moved but actually quarried from its position *in situ* at a level of 72 feet above high water spring tides; and higher up still there was another detached rock weighing no less than 24 tons tilted up in a peculiar position, and underneath, many numerous angular masses had been wedged, obviously by aqueous action.

But by far the most striking effects as yet recorded were at the harbour works of Wick, which were commenced in 1863, and consisted of blocks of from 5 to 10 tons set on edge, first built above high water mean tides with hydraulic lime, then with Roman and latterly with Portland cement. In October 1864, 200 tons of the concrete's staging were carried away; and greenhairs were afterwards substituted for Mamel piles, but those too were broken by the sea. The first portion of the wall was, in conformity with usual practice, founded at 12 feet below low water, but 18 feet was subsequently adopted, and the rubble has since been washed down to 15 feet below that level. In 1873 a huge monolithic block of concrete, weighing in all 1350 tons, was removed *in mass* out of its position and carried to lowland of the breakwater. Extraordinary as this may appear, it was surpassed in 1873, when another concrete mass which had been substituted for the one that was moved, was in like manner carried away, though it contained 1600 cubic yards of cement rubble, the weight of which was about 3000 tons.

Fig. 6.

The marine dynamometer was constructed by Mr. T. Stevenson for the purpose of ascertaining the force of the waves against an oblique plate. DEED (fig. 6) is a cast-iron cylinder, which is firmly bolted at the projecting flanges G to the rock where the experiments are to be dynamometer. This cylinder has a circular flange at D. L is a door which is opened when the observation is to be read off. A is a circular dial on which the wave's impulses, transferred to the dial are four guide rods B, which pass through a circular plate C (which is covered down

to the flange D), and also through holes in the bottom of the cylinder EF. Within the cylinder there is attached to the plate C a very strong steel spring, to the other or free end of which is fastened the small circular plate K, which, again is secured to the guide rods B. There are also rings of leather F, which slide on the guide rods, and serve as indices for registering how far the rods have been pushed through the holes in the bottom EF, or, in other words, how far the spring has been drawn out by the action of the waves against the disk A. These disks were from 6 to 9 inches in diameter.

The greatest result obtained by the dynamometer at Skerryvore Lighthouse, in the Atlantic, was during the heavy westerly gale of 26th March, 1845, when there was registered a force equivalent to 6083 lb. or nearly 3 tons, per square foot, deduced from the area exposed. The next highest was 5322 lb. In the German Ocean the greatest result obtained at the Bell Rock was 3018 lb. per square foot. But subsequent and much more extended observations at Dunbar, in the county of East Lothian, gave 24 tons; while at the harbour works of Buckie, on the coast of Banffshire, the highest result of observations, extending over a period of several years, was 3 tons per square foot.

Mr. David Stevenson, when referring, in 1835, to the Depth of lakes in North America, pointed out that the general depth of water must, in order to allow the waves to be fully formed, be considerable, and that the sea must be unobstructed by shoals, and also of sufficient area to admit of the wind acting fully on the water.

If in front of a harbour shoal water extends seawards for a considerable distance so as to form an extensive flat fore-shore, the depth of water above it becomes the true limit of the maximum wave, whatever may be the general depth of the sea outside. But at Arbroath harbour and at Alnemouth, the heaviest waves are whipped up by the shoal water near the mouths of the harbours, and are not found so dangerous to the works inside as the smaller waves which reach the beach in an unbroken state.

Mr. Scott Russell states that waves break when they Depth is come into water of the same depth as their height. At which Wick, however, the height of the waves above the mean level was about two-thirds of their height. In 1870, at Scarborough, it was found that waves of from 6 to 6½ foot broke when the depth was 10 feet 3 inches below their troughs, and 6 feet waves broke in water 13 feet 8 inches deep, which would for waves of this class give $A = \frac{3}{2}d$, where d is depth below mean level, and A the height from hollow to crest.

The late Dr. Macquorn Rankine has shown that, theoretically, the mean water level is not situated half way between the crest and trough of the sea. The following formulae furnished by him give the mean level of the sea from the height and length of the waves. These formulae are exact only for water of considerable depth as compared with the length of the waves. For shallower water they are only approximate:—

Let L be the length of a wave, H the height from trough to crest; then, diameter of rolling circle = $\frac{L}{\pi}$, radius of orbit of particles = $\frac{1}{2}H$, and elevation of middle level of wave above still water = $\frac{3}{4}H$.

Consequently—

$$\text{Crest above still water} = \frac{H}{2} + \frac{7854 H^3}{L^3};$$

$$\text{Trough below still water} = \frac{H}{2} - \frac{7854 H^3}{L^3}.$$

Deep-Water Harbours.

Harbours of refuge are distinguished from tidal harbours mainly by the superior depth of water which they possess and the larger area which they enclose. The requisites are—shelter during storms, good holding ground, and easy access for shipping at any time of tide and in all states of the weather. A breakwater, though a passive, is yet a real agent, having true work to do. During storms many thousand tons of water are elevated and maintained above

the sea level, and a breakwater has to stop them onward motion within a given space or else to change the direction of their movement. There are two ways in which this work can be performed. One is by means of a plumb wall to alter the direction of the moving water by causing it to ascend vertically, and then to allow it to descend vertically, by which process the waves are reflected and sent back seawards. Another mode is to arrest the undulations by a sloping wall of length sufficient to allow the mass of elevated water to fall down upon the slope. If, however, the slope is not long enough to enable the waves to destroy themselves, they will, though reduced in height, pursue their original direction and pass over the top of the breakwater. In this case the breakwater does not do its full amount of work, and imperfect shelter is obtained.

The principle asserted in favour of the vertical wall is that oceanic waves in deep water are purely oscillatory, and exert no impact against vertical barriers, which are therefore the most eligible, as they have only to encounter the hydrostatic pressure due to the height of the impinging billows which are reflected without breaking.

From the effect of winds and tide-currents already referred to, and perhaps from other causes, the action of which seems to have been overlooked by the advocates of the upright wall, we have good reason for believing that any form of barrier, in whatever depth of water it may be placed, must occasionally be subjected to heavy impact. The possibility of waves of translation being generated in the deepest water is established by the following facts—*first*, that oceanic waves break, partially at least, long before they reach the shore, because (as admitted by the advocates of the purely oscillatory character of oceanic undulations) the depth of water is too small to admit of their being fully propagated; *secondly*, that waves in strong tide-ways break in deep water during calm weather—a phenomenon which is apparent to the eye and familiar to all sailors, *thirdly*, and negatively, that to leeward of these races which produce broken waves, and which certainly do not reflect the incoming waves, there is comparatively smooth water both at sea and on the adjoining shore until the strength of the tide is exhausted and the race has disappeared, after which violent action is again fully manifested on the shore. Even a vertical wall, if built of ordinary masonry in courses, must during its formation present to the action of the waves at its unfinished end a sloping or at least a stepped face like a talus wall, but which, unfortunately for its stability, possesses none of the advantages of such a finished work. In short, during the most critical period of the history of every built vertical wall, the face work and hearing are exposed, at the outer end, to the force of breaking waves. At Dunbar the force against the unfinished end of a nearly vertical wall was found by the main dynamometer to be nearly six times greater than on the face of the finished wall, where the waves were at the time purely oscillatory.

Oblique
force in
vertical
plane

An important advantage of the sloping wall is the small resistance which it offers to the impinging wave, but it should also be borne in mind that the weight resting on the face stones in a talus wall is decreased in proportion to the sine of the angle of the slope. If we suppose the waves which assail a sloping wall to act in the horizontal plane, the component of their impulsive force at right angles to the surface of the talus will be proportional to the sine of the angle of inclination to the plane, while the effective force estimated in the horizontal plane will be proportional to the square of the sine of the angle of inclination. But if we assume the motion of the impinging particles to be horizontal, the number of them which will be intercepted by the sloping surface will be also reduced in the ratio of the

sine of the angle of inclination, or of the inclination of the wall to the vertical. Hence the tendency of the waves to produce horizontal displacement, on the assumption that the direction of the impinging particles is horizontal, will be proportional to the cube of the sine of the angle of elevation of the wall.

If it further happens that, owing to the relative direction of the pier and of the waves, there is an oblique action in azimuth as well as in altitude, there will be another similar reduction in the ratio of the squares of cubes of the angle of incidence, according as the component of the force is reckoned at right angles to the surface of the pier or in the direction of the waves.

Let f = force of the wave on unit of surface of wall for pier perpendicular incidence,
 f' = force on unit of surface at vertical incidence ϕ and azimuth of incidence ψ ,
 $f' = f (\sin \phi \sin \psi)^2$

The amount of shelter which is produced by a breakwater pier must be measured by the length of the portion of wave which is either destroyed or reflected by it. The amount of work done by it decreases from the maximum, which is at normal incidence, to zero when the waves come upon it "end on," in which last case it ceases to act as a breakwater at all, unless to the extent due to lateral friction or cohesion where there is a wall or a slope on which the end of the waves can break.

If a breakwater be so situated in relation to the coast line that waves may strike obliquely upon its inner or sheltered water side, an extension of its length in the same direction will increase the amount of sea intercepted by it. The lengthening of a breakwater may therefore, during certain winds, increase the sea within the harbour instead of reducing it. In such a case the extension should, if possible, be made in a different direction, or a separate breakwater may be brought from the shore so as to shelter the inner side. If these works cannot be undertaken, then an addition to the sheltered space within must be provided in which the waves can spread, or additional slopes be provided on which they can break.

The table of the principal proportions of some of the most remarkable breakwaters given on p. 460 may be found useful as a guide in designing works of a similar kind.

The following costs of different breakwaters are from the Cost Minutes of the Institution of Civil Engineers and other sources—

Name of Breakwater	Depth of Water in Fathoms	Cost per Lin. Foot	Cost per Tm. and	Remarks
Joliette, Marseilles	6 to 8	72	216	
Marseilles (new)	6 to 6.6	109	328	
Futland ..	6 to 10	116 to 130	348 to 390	Concret labour, all large bottom blocks
Algiers	6 to 9	122	366	
Holyhead	8 to 7	about 168	480	
Almamey	3 8	170	510	
Plymouth ..	6 to 7 6	200	600	
Dover	6 to 8 3	260	1080	

Although some of these prices have given rise to lengthened discussions as to the comparative economic advantages of the various designs, the results have not been of much value on account of the different degrees of exposure and of depth of water at the various places. The economic values may perhaps be arrived at in a more satisfactory manner, although still but only very approximately, thus—When x = the price per foot of depth, p = the

Table of principal Proportions of remarkable Breakwaters

price per lineal foot, and d = the depth in feet at high water, then

$$a = \frac{P}{d}$$

The results calculated in this manner are arranged in order of their costs in the following table, from the pier at Dover appears to be by far the most costly—

Name of Harbour	Depth in Feet at High Water	$\frac{P}{d}$
Portland	62	£1 80
Almarsey	35	2 00
Almarsey	43	3 00
Almarsey (low)	35	3 10
Plymouth	55	3 45
Holyhead	58	4 40
Almarsey	37	4 50
Dover	38	9 47

Minard allows for large merchant vessels in harbours of refuge one cable-length, which would give about four vessels per acre. Captain Cairer allows three vessels per acre for a small sheltered harbour of refuge. At Cardiff there were at one time 224 vessels anchored so close to each other as they could well be, in an open roadstead, and occupying a space of 560 acres, which would give 0.4 vessel per acre.

Tidal Harbours

We have hitherto been considering outer breakwaters erected in deep water, and which are constantly exposed to the waves, we now turn to piers and sea-walls which are placed within the range of the breaking surf, and which are exposed to its force for a limited period only, being sometimes left nearly or altogether dry by the receding tide.

In dealing with the question as to how this force may be best resisted—whether by opposing to it dead weight, or a comparatively light structure, the stability of which is dependent on strong fixtures connecting it with the bottom. On this subject the late Mr Alan Stevenson made the following remarks, in relation to highwater

towers, but his views are equally applicable to piers and breakwaters—

"A primary inquiry in regard to towers in an exposed situation is the question whether their stability should depend upon their strength or their weight, or, in other words, on their cohesion or their inertia. In pursuing weight to strength we more closely follow the course pointed out by the analogy of masonry, and thus must not be misled by a mere notional advantage for the more close the analogy between art and nature, and the less difficulty we shall experience in passing from nature to art, and the more directly will our observations on natural phenomena bear upon the artificial project. If, for example, we in like a series of observations on the force of the sea as exerted on masses of rock, and endeavour to draw from these observations some conclusions as to the amount and direction of that force as exhibited by the waves of rock which resist it successfully, and the form which these masses assume, we shall find virtually to the determination of the mass and form of a building which may be capable of opposing similar forces, is we conclude with some reason that the mass and form of the natural rock are compounds of the amount and direction of the forces they have so long continued to resist. It will readily be perceived that we are in a very different and less advantageous position, when we attempt, from such observations of natural phenomena in which weight is solely concerned, to deduce the strength of an artificial fabric. Another very obvious reason why we should prefer mass and weight to strength as a source of stability is that the effect of mass inertia is constant and unchangeable in its nature, while the strength which results even from the most judiciously disposed and well executed fixtures of a comparatively light fabric is constantly subject to be impaired by the loosening of such fixtures, occasioned by the almost incessant tremor to which structures of this kind must be subject from the beating of the waves. Mass therefore seems to be a source of stability, the effect of which is at once appreciated by the mind as more in harmony with the conservative principles of nature, and unquestionably less liable to be determined than the strength which depends upon the careful proportion and adjustment of parts."

It is a remarkable fact that during a summer gale 14 effect of blocks, each 2 tons in weight, which had been permanently fixed in the Dhu Hartach lighthouse tower by joggles and cement, at the level of 35½ feet above the sea, were torn out and swept off the rock, while the thin panes of crown glass in the lantern of Winstanley's Eddystone tower, which were only about 5 feet higher, resisted the waves for a whole winter. The impact on marine masonry seems to be

¹ Account of the *St. Mary's Lighthouse*, by Alan Stevenson, Lt. B., F.R.S.E., Edin., 1848, p. 49

therefore to depend on the relation subsisting between the height of the waves at the place and the height and configuration of the rock itself above and below low water, and perhaps also on the configuration of the bottom of the sea near the rock.¹ While the rock at Dju Heatlach from its height above the sea forms a protection against the smaller waves, it operates as a dangerous conductor to the larger waves, enabling them to exert a powerful action at a much higher level than if the rock had been lower. It is of great importance that these facts should be kept in view, and that the Eddystone should not be regarded as a safe model for imitation at all rocks which are exposed to a heavy sea.

side of
masonry

The impact of the waves against the outside of a sea wall or pier gives rise to four distinct forces, namely—(1) the direct horizontal force, which tends to shake loose, or drive in, the blocks of which the masonry consists, (2) the vertical force acting upwards on any projecting stone or protuberance, as well as against the lying beds of the stones, (3) the vertical force acting downwards, which results either from the receding wave striking upon the toe of a talus wall, or from its passing over the parapet and falling upon the pitching behind, so as to plough it up, (4) the "backdraught," which tends by reaction from the wall to remove the soft bottom, and in this way to undermine the lower courses or to suck loose stones out of the work.

It may be concluded from the above that the points which require to be most attended to are—the contour and quality of masonry of the wall itself, the parapet, which if not of proper form, or of insufficient height, leads to damage in the pitching behind it, and lastly, the foundation-course, in the design and construction of which, if similar precautions be not attended to, undermining of the bottom may take place, so as to leave the lowest courses without protection.

Force
within
the
masonry

Within the masonry, as well as without, the waves exert force in the following different ways—(1) by the propagation of vibrations produced by the shock of the waves on the outer or sea-wall, through the body of the pier to the inner or quay-wall, (2) by the direct communication of the impulses through the particles of the fluid occupying the interstices of the heating, so as to act against the back joints of the face stones of the inner quay, (3) by the sudden condensations and expansions of the air in the heating, so as to loosen, and at last to blow out, the face stones of the quay, combined with (4) the hydrostatic pressure of the water, which is forced through the sea-wall, and, from want of free exit, is retained and acts as a head at the back of the quay, and which, however small in quantity, will, as in a Bramah press, act with equal force upon all surfaces exposed to its pressure, however large those surfaces may be. The last three causes are probably the most efficient agents in the work of destruction.

From a comparison of different piers in the German Ocean where we have most examples, and from careful consideration of the other data, it appears that vertical piers, fully exposed to the ordinary waves of that sea, should be not less than from 35 to 45 feet broad at the level of high water. Of course this remark does not apply to anomalous cases where waves are exceptionally high, but, as already stated, to works exposed to the ordinary waves.

The positions in which the piers are to be placed depend on the nature and configuration of the shore and of the

bottom. After a correct plan, with soundings, has been obtained, the next step is to lay down contour lines of the different depths which make the limits of the deep and shoal water at once obvious to the eye. The lines of the piers may then be sketched so as, without disregarding other conditions, to keep the works as much as possible on the shoal ground, while they at the same time enclose the greatest possible area of deep water.

The entrance should be fixed seaward of every part of the works, and its direction, unless where the internal area is small and the sea very heavy, should if possible be made to coincide with that of the heaviest waves, so that they may run along with and guide vessels into the harbour.

Fig 7

The outer pier should in such a case be extended sufficiently far seaward of the end of the inner pier head to give it a free end, as in fig 7, thus allowing a ship plenty of sea room to shape an easy course before taking the entrance to the sheltered basin of the harbour.

There should be sufficient distance landward of a harbour mouth to allow a vessel, having full weigh on her, to shorten sail. For this Minor accommodation that, where vessels of ordinary size require to alter their course in order to reach the inner basin, no circle with a less radius than 200 yards in smooth water should, if possible, be adopted, and it should not be forgotten that a vessel requires a larger radius in turning where the water is shoal than where it is deep.

If the beach consist of travelling detritus, the entrance must be so devised as not to form a trap for the passing shingle. This danger is most to be dreaded on the coasts where heavy waves strike obliquely upon the shore. Finally, there must be a good "loose," so that vessels on leaving the harbour shall be able to shape their course free of rocks or a lee-shore, and Minor a very properly remarks that the mouths of harbours should be designed rather to suit the entering, which is far more important, than the exit of vessels.

Preference should generally be given to a pier of horizontal convex outline, or a polygonal form, than to one long straight pier. The principal objection to a straight pier does not, however, extend to cases where the heaviest waves strike upon it obliquely, and roll landwards along the sea-wall. Especial care, however, must in all cases be taken that a sea-work nowhere presents to the sea a surface of concave horizontal outline, or, what is still worse, abrupt faces which form a re-entrant angle, for the waves will then act with an almost explosive violence, the breaking of a free wave being a very different thing from the breaking of a wave confined by a barrier of masonry. While the first may be compared to the harmless ignition of a loose heap of gunpowder, the other resembles the dangerous explosion produced by the discharge of a cannon.

¹ Mr D. A. Stevenson has lately shown that a funnel-shaped depression in the sea bottom extends from the ocean in the direction of, and nearly as far as, the Dju Heatlach rock, a geological formation which must certainly admit the heaviest class of waves to come nearer to the rock (*Ann. of Proc. of the Inst. of Civil Engineers*, vol. xvi.)

8.8 feet, but the formula for distances so short as this would give waves about 4 feet higher, and in heavy storms perhaps waves not much less than 5 feet in height, but on such occasions vessels could not safely use the gun.

In order to tranquillize harbours of small rodents power, logs of timber called booms, having thus ended, secured by projecting into grooves cut in the masonry on each side, are placed across the entrance of the inner basin or dock. From 15 to 23 logs are usually dropped into those grooves, or as many more as will insure close contact of the lowest log with a sill-piece, placed in the bottom of the harbour. They are also warped down or fixed with an iron baulk at the coping course, without which precaution the well is full of water, and the boats are under the waves. By this contrivance, which forms a temporary wall, the waves are checked, and completely prevented from spreading into the interior basin.

Twelve inch booms of pine timber about 33 feet long have been broken at the small fishing village of Mousehole, near Penzance, and elm logs have in consequence been substituted. At Hynish in Argyllshire, booms of the same timber and scantling and 30 feet long have been very frequently broken. The marine dynamometer at this place gave 11 ton per square foot.

Capacity of harbours for commerce—The capacity of commercial harbours for trade varies so much with the exposure and size of vessels that it is difficult to approximate to the truth. At Ramsgate, for instance, there were found to be about 6 vessels to an acre in the outer harbour, while there were about 14 in the inner and better protected basin, where too there was perhaps a greater proportion of small vessels. In the Scotch fishing harbours the number of boats used to be reckoned at from 85 to 115 per acre, but of late times it has been much increased, and probably not more than from 50 to 90 could be accommodated. The Danish boats at New Ferry, according to the Channel pilot, vary from 60 to 80 per acre.

The employment of timber in Indian works is of great antiquity. It seems first to have been used in furring boxes which were filled with stones, and at a more recent period in the formation of open frameworks through which the cement could be cast freely. Vitruvius mentions masonry, consisting of timber filled with stones and cement, as having been used by the Babylon-builders in his days! The earliest drawing of timber posts that we have met with is that of the ancient port of Dunkirk in 1690, a cross section of which from Balldor's *Architecture à l'usage civil* we give in Plate VIII, fig. 1. The kind of masonry is still not uncommon on the coasts of the English Channel.

In sheltered bays where a deep water landing-place is not, as that is required, and where the bottom is sandy or soft, timbers may be employed with great advantage. Even in somewhat exposed situations it can also be used for tidal rafts, but the fatal evil in places where there is no abundance of fresh water is its rapid destruction by marine insects. In the Atlantic Ocean the *Teredo navalis*, and at many places in the Gormin Ocean the *Limnoria terrena*, which was first discovered by the Lieut Mr Robert Stevenson at the Bell Rock Lighthouse in 1810, are the most destructive of most kinds of timber. Mr Stevenson found that mangel was destroyed by the *Limnoria* at the rate of about one inch inwards per annum. To found that growth of heart, beefwood, African oak, and bullion tree was greatly

attacked, while teak stood remarkably well and locust tolerably well, though suffering at last. Greenheart timber, though not absolutely unresistant, as appears from Mr. Steven's experiments, is the great species in seas where the worms are destructive. But subsequent experience has proved that on the coasts of Scotland it is, in some cases, readily attacked, and at those places cloosoting is of comparatively little use, as the worm manifests no repugnance to timber which has been even very recently impregnated.

In addition to the experiments on timber, twenty five Duna different kinds and combinations of iron were found to oxidize with the Boil Rock, including specimens of galvanized iron. All the ungalvanized iron was found to oxidize with the same rapidity as the galvanized iron. The iron subjected to isolated oxidation for three or four years, after which the chemical action went on as quickly as in the others. Although the association of zinc with iron protects, so long as it lasts, the metal with which it is in contact, it must be remembered that this immunity is obtained at the expense of zinc, the tendency of which is to be oxidized. Eventually it is oxidized as soon as any part of the iron is exposed.

The important experiments of M. Mallet on spontaneous sunken in the one showed that the amount of spontaneous decayed with the thickness of the casing, and that from 15th to 15th inch in depth, in castings 1 inch thick, and about 15th inch of wrought iron will be destroyed in a century in clean salt water. That there is reason to believe from a cannon ball which was picked up on the shores of the island of Inokoth that the decay was in that case 15th inch to the century. Cast-iron girders partially immersed by the tide at the Boll Buckle lost at the rate of 1 inch in a century. Even when the castings were externally wound their strength was reduced one half in about 50 years.

In judging of the quantities of different quantities for harbor purposes the importance of a high specific gravity of concrete ought not to be overlooked, as appears from the table given on page 444.

Materials of construction

The superiority of granite to gneissstone is proved by the following experiments on the times required to abrade 1/4 inch of each kind of stone, made with the same weights and grinding agents, and with equal cubes of each material—30 minutes were required for Quousville (Carlin Nose) gneissstone, 40 minutes for gneissstone from Banton near Edinburgh, 60 minutes for Peterhead granite. Mr Murray of Dundee also established, many years ago, the superior power of resistance to attrition possessed by granite over gneissstone.

Portland cement rubble and concrete, a most valuable Portland material, now very commonly used in Britain as well as on the Continent, may be said to have to a large extent revolutionized harbor building, for it admits of being employed in many different ways, and can, if due care be taken as to the quality of the cement and purity of the sand and gravel, be used with perfect confidence.

The following specification has been followed extensively at different places —

The Portland cement is to be obtained from the best manufactory. It is to be good extremely fine, and is to contain not less than 115 lb per bushel, and each cubic will, on its arrival at the works, be tested in the following manner. The cement is to be made into small blocks 1 inch square and 8 inches long. After being made, these blocks are to be immersed in water for 7 days and then tested by being placed on two supports 6 inches apart, when they must stand the transverse strain produced by a weight of 70 lb placed in the centre. Slabs of coke are also to be made and placed in water, and after immersion of 7 days, they are not to show any signs of decay or fracture, and the surface of the coke

The cement is to be tested before any of it is used, and if it be found unsatisfactory it must be removed from the works. When a cargo is landed it must be tested from four different bags, and it must also be tested weekly as the works proceed, and the results forwarded to the consular. The cement must be brought direct

¹ It was probably to some such work that Horace refers in Ode 1, Book iii —

¹¹ *Conti acta plicae equosque sentiunt,
Tactis in altum molibus, hinc frequens
Craemona dimittit redemptor.*"

A harbour contract dated 1394, in all probability the earliest which has been preserved, appears in the *Registrum Nigrum de Aberbrothoc*—a collection of ancient documents printed by the Bannatyne Club, and edited by the late Professor Cosmo Innes.

from the manufactory and kept at the works in a dry and well ventilated stonehouse with dry wooden floor and solid walls, properly roofed in and completely protected from the weather.

The concrete to be used is to consist of one part of Portland cement, two of sand, and five of gravel, to be thoroughly mixed with 17 1/2 parts of water. The concrete is to be made in a large tub, and the quantity of pure water, after it is deposited, large angular stones are to be added, one being taken that all the stones are completely surrounded by concrete to a thickness of not less than 4 inches. All stones to be clean and quite free from wet mud or other objectionable matter likely to prevent the adhesion of the concrete. No concrete to be made during frost. The sand and gravel used must be sharp and clean, being perfectly free from clay or earthy matter.

There are different kinds of machines by which the concrete is thoroughly mixed, and a saving of cost effected. In that of Mr. Messent the number of revolutions to mix the concrete thoroughly is twelve.

Continuous building

The walls of harbours may be constructed of continuous building of concrete and stones, protected by temporary piling and close planking. The best mode of keeping out the water, as adopted by Mr. Balmer at the duke of Richmond's harbour of Port Gordon, is to make a saw draft in each plank, and to place a thin plate of iron between the planks. An example of this continuous or monolithic building is shown in Plate VIII. See also

M^r B. B. Stoney has deposited at Dublin the largest blocks that have as yet been attempted to be moved.

Each block is 27 feet high, 21 feet 4 inches wide at base, and 12 feet long in the direction of wall, contains nearly 5000 cubic feet, and weighs 360 tons, and when laid in place 12 linear feet of the wall is finished at once up to ordinary low water level. No cofferdam, diking, or pumping is required. The superstructure is built in the ordinary method by tide work, and is faced with granite ashlar for the slope to the sea again. The blocks are built on land, and after 10 weeks' drying are lifted by floating sizers, the largest or portion of which is 180 feet long and 48 feet wide, and of this 180

float 30 form a tank at the wind, and, when filled with water, this balance, the weight of the block hanging from the shows it the other one. A block can be raised with the flood tide, and is generally not the following low water.

The late Mr J M Rendell introduced the improved and Depository valuable method of depositing the *perceps pedius* or rubble, which is now generally used in the construction of large breakwaters. This method he employed first at Milbury pier, near Plymouth, in 1838, in a depth of 38 feet, and afterwards, on a still larger scale, in the construction of the breakwater at Falmouth, in 1841.

section of the breakwaters at Holyhead and Portland. The stones are conveyed in depositing the rough materials from the barges to the shore by means of a small crane, and are then conveyed to the strapping of timber, placed in a small boat, and are then conveyed to the shore. The stones are brought on the strapping in waggons, through the bottom of which they are discharged into the sea. The principle on which these strappings are designed is that of allowing the smallest possible headway to the waves, the under slats turn oversteering of nothing more than single upright slats. The strapping is designed to be a low, but without work, as already stated, it was found that the pulsed of the strapping for depositing the rubble acquired to be of general art timber, but even those were broken in large numbers. The piles were invariably broken by the waves at about the level of high water.

A depth of from 12 to 15 feet under low water was Level of
pointed out by Mr Rendel as the level below which the conser-
rubble was little or no damage to *the res pectus*. Sir John vation of
Rennie indeed considered that there was little or no effect rubble
at a fathom and a half. But at Wick, as already stated,
the rubble was moved as low as 15 feet, and at Alderney
20 fathoms.

If the beds of the stones in a sea-wall were polished, the level of
power of resistance would be reduced by about one-fourth. *the res*
or in other words, roughly dressed materials of three-fourths *the res*
the weight of polished materials will be equally safe. dressing

There is also good reason to believe that slopes of large *marina puerile* are preferable to slopes of diverse masonry. The great object to be attained is the maximum amount and uniform distribution of friction.

Iron piles. Piles of cast and of malleable iron are now frequently employed. Examples of these may be seen at Seaborough, Southport, Portobello, and at many other parts of the English coast, and have been found to answer even where there is a considerable sea.

The piles at Southport, described by Mr H. Hooper, are of cast iron, and the most of them, sinking the piles were pushed. The piles, proper in lowest lengths of the columns are cast in lengths of 8 feet and 10 feet, and are sunk into the sand to the depth of 1 foot and 9 feet respectively. They were provided with circular disks 1 foot 6 inches in diameter, to form a bearing surface, and a small hole being left in the centre, a wrought iron tube 2 inches in diameter was passed down the inside of the pile, and forced about four inches into the sand, a connection being made by two iron disks, one between the top of the tube and a temporary pipe connected with the Water Company's mains, and extended to the sinking of the pile proceeded. A pressure of water of about 50 lbs per inch was thus obtained, and this was found to be sufficient to force the sand down under the disk. Each disk was provided on the lower side with cutters, which, on an elevating motion being given to the pile, loosened the sand. The piles were gradually lowered, and guided by a small ordinary piling engine. When the pressure of water had been removed about 5 minutes, the piles settled down to an amount bearing that when tested with a load of 12 tons each no signs of settlement could be perceived. The cast-iron columns are 7 inches in external diameter, and 5 inches in internal diameter. All the piles, to the number of 237, were sunk in six weeks, being at the rate of between 6 and 7 in twenty-four hours.

The Cleveland quays are of malleable iron. Mr J. W. Glover states that each wrought column of the Bales rails weighing 80 lbs to the yard, riveted back to back, and having a total section for each 100 feet span of 61 inches. They are laid together by diagonal tie rods from 10 to 25 feet apart, and are braced by means of the piles below low water are of solid wrought iron 7 inches in diameter, shod with cast-iron shoes 2 feet in diameter, and were driven down till 13 inches iron piled round 6 feet 6 inches into the sand with the ship. They penetrated the ground to depths varying from 7 to 17 feet, and though made with a thickness of 6 inches in pitch seldom descended more than 23 inches or 3 inches in a year. The solid piles were so connected with the Bales rail piles by cast-iron shoes. Where rock occurred below were rammed, and a 1-inch wrought iron bar was riveted and secured by a jugged key. A door to receive the Bales rail was fitted and keyed on this, and the remaining space was filled with iron cement. The length of the lower pile is 76 feet. The level of low water is 16 feet above extreme high water, and the height above the ground at the pier head is about 68 feet.

Deposits and Sinking

Deposits arise from two essentially opposite causes, viz., commotion and stagnation of the water. They are also of different kinds of material—(1) those lighter matters, such as mud, silt, and fine sand, which are held for a time in mechanical suspension, and which, as the water approaches stagnation, are gradually dropped in the order of their specific gravity and mass, and (2) those grosser matters, such as different kinds of sand and gravel, which are rolled along the bottom or driven forward with the water by the action of waves and currents. The first-named are deposited on the lee side of piers or groins which obstruct the progress of the waves or currents, while the second accumulate on their weather sides. But the amount and the position assumed by the deposits of the second kind depend on the direction and force of the waves or currents in relation to the shore and to obstructions. The amount of deposits of the first kind are little dependent on the direction of the stroke of the waves outside of the basin or sheltered places in which they are deposited.

Artificial scouring. The preservation of the depth of harbours at a level lower than that of the original bottom involves both uncertainty and expense. Where the deposit is confined to the space between high and low water-marks, the scouring

by means of salt or fresh water is comparatively easy, but when it forms a bed outside of the entrance, the possibility of maintaining permanently a greater depth becomes very doubtful. The efficacy of the scour, so long as it is not impeded by enlargements of the channel, may be kept up for great distances, but it soon comes to an end after it meets the sea. When the volume of water liberated is great compared with the *alveus* or channel through which it has to pass, the stagnant water which originally occupied the channel does not to the same extent destroy the momentum as when the scouring has to be produced by a sudden finite impulse. In the one case the scouring power depends, *ceteris paribus*, simply on the relation existing between the quantity liberated in a given space of time and the sectional area of the channel through which it has to pass, while in the other it depends on the propelling head, and the direction in which the water leaves the alveus. Mr Rendell's scheme for Dickenhead was on the former principle, which it must be recollected is only applicable where the soil is easily stirred up.

The first example of artificial scouring in England seems to be due to Smeaton, who used it effectively at Ramsgate in 1779. At Bute Docks, Cardiff, designed by the late Sir W. Cubitt, the access to the outer basin is kept open most successfully by means of artificial scouring on a large scale.

Munroe holds that when a channel has to be maintained by regular and habitual scouring, the whole effect is generally produced in the course of the first quarter of an hour. This was made the subject of particular investigation at Dunkirk, where sections of the channel were made before and during the scour, and it was found that there was no alteration in the sectional area after the first quarter of an hour.

Causes of Increase of Height of Waves

The following causes increase the height of waves in a harbour—(1) the removal of a spending beach either at the entrance channel or within the harbour by building a quay or talus wall across it; (2) deepening the entrance channel or the basin of the harbour itself,—thus the difficulty of keeping vessels to their moorings at the quays of a harbour increases during flood tide, just as the tide rises and the depth is thereby increased; (3) removal of an artificial breakwater or a protecting point of land or spit of gravel outside of the harbour; (4) filling up side rocks or lateral basins in a harbour or its entrance channel; (5) shortening the distance between the sea and the entrance to an inner basin or dock by projecting the basin or dock farther out from the shoreline so as to bring the gates nearer the sea entrance, or projecting the mouth of a harbour farther seawards; (6) removal of a petty or filling up an artificial side chamber or converting talus into a plumb wall; (7) straightening an entrance channel or an outer side breakwater or walls within a harbour; (8) widening the entrance or the entrance channel; (9) reduction of the area of the basin of the harbour; (10) making smoother the surface of a natural sloping beach either within or outside of a harbour by pitching its surface; (11) lowering the top of a protecting outside breakwater over which the sea breaks; (12) converting an open timber quay into a close quay; (13) lengthening a breakwater so as to intercept a greater portion of the waves which come in certain directions.

II DOCKS

Docks are of two kinds, viz., dry or graving docks, and wet or floating docks. The dry or graving dock is a small water-tight chamber, fitted with gates of timber or iron, which are shut against the rising tide after a vessel has

cutted for the purpose of being repaired. The water below low tide level is pumped out generally by steam power.

Wet locks. The wet dock or tide basin is a large water-tight inclosure, usually several acres in extent, which is also fitted with gates which are closed, not, however, during the flowing but the ebbing tide, so that the vessels lying at the quays within the basin may remain constantly afloat and nearly at the same level while being loaded and unloaded.

Locks. In order to extend the time during which vessels can enter or leave a wet dock there are two additional works which are often connected with it. These are the entrance-lock and the outlet or half-tide basin. The lock is a narrow chamber of just sufficient length and breadth to admit a ship of the greatest length and breadth of beam that is expected to frequent the port. Such a lock can, in absence of the largest class of ships, accommodate simultaneously three or four vessels of smaller tonnage. Locks are sometimes made with double gates, so that when only one vessel of small size has to enter, she is shut up within a compartment of the lock, by which means some of the water is saved which would have been expended had the whole of the chamber been filled. Shortly after the tide has begun to ebb, and when the gates of the wet dock have been shut, in order to prevent the water from falling too low in the dock, a vessel can still enter or leave by means of the lock. She is first passed into the lock from the sea, and, the lower or sea gates being closed, the sluices in the upper or dock gates are opened, which raises the water in the lock chamber to the same level as the water in the dock, when the upper gates are opened to let the vessel pass in. Ships leaving the dock after the tide has begun to fall are passed into the lock chamber, when the upper gates are closed and the sluices in the lower gates are opened, until the water in the lock has fallen to the same level as the tide outside, when the lower gates are opened and the vessel goes out to sea.

This system of locking is continued so long as the level of the dock is not so much depressed as to affect the loading or unloading of vessels lying at the quays, or until the tide has ebbed so far as to prevent vessels reaching the lock from the sea. At the West Dock, Cardiff, where the level is kept up by fresh water from the river Taff, the gates, in order to suit the rise and fall of the tide, are opened one hour before and about two hours after high water.

Tide basins. The tide basin may be described as a lock of very large dimensions capable of receiving at the same time a considerable number of vessels, which continue to run into it from the sea after the dock gates have been finally closed for that tide. Such vessels can run in, so long as they have sufficient water over the sill of the sea gates of the basin, or until the basin itself is filled with ships. The sea gates are then closed, and the sluices in the upper gates are opened till the water in the basin is on a level with the water in the dock. The ships are then passed continuously into the dock, in a string, one after the other. By means of this arrangement the traffic can be carried on to a far greater extent than is possible with a narrow lock, which has to be filled and emptied for each vessel that enters or leaves the harbour. The late Mr Jesse Hatfield of Liverpool was the first to propose half-tide outlet basins, as adjuncts to wet docks.

Advantages of docks. The peculiar advantages of docks are the following. Vessels can be accommodated in the smallest possible spaces, and are enabled to lie constantly afloat, whereas in tidal harbours, where they take the ground, they are apt to be strained or to have their floors broken. But there are other sources of mischief than this in open harbours, for often, when the tide is ebbing, vessels, unless watched, fall

against each other. In two instances where the bottom, which was muddy, had a considerable delivery, a ship which had taken the ground on the beach near low water mark was actually run down and damaged by another stranded vessel, the warps of which suddenly snapped and frod her from the moorings at the quay, thus causing a collision between vessels both of which were at the time high and dry. Then there is the chafing of the vessel's sides against the quays in exposed harbours where there is a run of sea, and the backing of warps during stormy weather, or during land floods, which there is a river. The late Mr James Walker stated that at Sunderland damage to the extent of £40,000 was occasioned in a single day by large quantities of ice that came down the river Wear. When a vessel is in dock she can be easily and at all times moved from place to place, and the operation of discharging and loading can go regularly on during all times of tide. Her level, too, is never much affected, so that the cargo does not require, when being discharged, to be hoisted so high as would otherwise be necessary. Timber vessels can be unloaded through their ports into the water at all times of tide, while in harbours which are dry at low water the cargo receives injury by falling on the hard bottom.

From the general description which we have given the following conclusions may be drawn as to the best facilities for docks.

(1) Where the rise of tide is considerable, a dock is but more required than where the rise is small. In rivers, such as the Clyde and the Foyle, for example, where the tide rises only from 9 to 10 feet, the inducement to construct docks is not so great as at the Mersey or the Bristol Channel, where the tide rises from 20 to 50 feet.

(2) Where the nature of the trade requires ships of great length, which are therefore very liable to injury from taking the ground, a dock is more needed than at places where the vessels are of smaller size, and therefore less liable to be stranded when not water borne.

(3) Where the bottom is soft and muddy, there is less need for a dock than where the bottom is hard and uneven, unless when strong currents are likely to batter out the soft soil so as to make the bottom irregular by forming deep runs.

(4) Where the harbour is open to the entrance of surface waves of considerable height, or of a ground swell, there is more need for a dock than where there is better protection.

(5) Where there is sufficient fresh water, free from mud or salt, for supplying the basin, a dock will be more suitable than where the supply is from the tide, especially if the sea at the place be much loaded with matter in mechanical suspension.

In designing a dock the first subject to which the engineer's attention must give his attention is the nature and extent of his proposed work. Of course no precaution is needed on this head if the place be a landlocked bay, or a narrow river or estuary. But if there be a considerable fetch of open sea, the waves generated during gales may be of such height as to endanger the sea gates or to interfere with their being worked in stormy weather. The formula already given at page 457 for short lengths of fetch will be the most suitable for calculating the exposure of docks, where the fetch ought never to be great.

Having calculated by means of this formula the height of waves that may be expected to reach the dock gates, the engineer must then determine whether such waves are too high for the strength of the gates, or for their being properly worked in stormy weather. Now we have unfortunately but few facts on this subject to guide us, and these not very consistent with each other.

Height of Waves in which Gates can be Worked.

Name.	Width of Entrance in Feet.	Height of Waves in which Gates are worked in Feet.	Authority.
Androssen.....	40	2	Mr Moffat, C.E.
Sunderland.....	36	2	
Sunderland, North.....	60	3	Mr Moik, C.E.
Do. South.....	40	2	
Silloth.....	60	3	Mr Boyd, C.E.

It might at first sight be expected that the strain would increase as the squares of the breadth of the gate, but, owing to the manner in which the forces are distributed, this does not seem to be the case.

Where b = the width of opening of the entrance in feet, and h = the height of the waves at the place, the formula $b = \frac{60}{h}$ may perhaps be regarded as safe; or, where h has not been observed, and D is length of fetch in miles,

$$b = \frac{60}{1.5 \sqrt{D + (2.5 - D)}}$$

Should the calculation by the formula give higher waves than are compatible with safety or convenience, the proper course will be to provide an outer harbour or covering breakwater, so as to reduce the height of the waves. For this purpose the formula given at page 462 is applicable. In cases where the course now recommended cannot be adopted, from motives of economy or from other causes, recourse may be had to protecting booms such as are described at page 463. If the traffic be considerable and the interruption caused by the shipping and unshipping of the booms be regarded a formidable objection, the gates may in some cases be protected by fastening together the tops of the mitre posts by chains. Another mode of securing gates against the sea was adopted at Ramsgate by Mr Ramsay, and is stated by Sir John Coode to be perfectly satisfactory. It consisted of the following arrangement:—

"One end of a stout beam or stay of greenheart timber was connected, by means of a screw iron movable joint, to the fore part of each gate, near the middle posts on the inner or basin side, and at about the level of high water of equinoctial spring tides; the opposite end of this beam passed into an opening in the masonry of the side walls of the entrance. The inner end of this beam was supported by a small bogie truck running upon a pair of rails laid in a horizontal plane. On the vertical face of the beam nearest the gate there was a strong toothed rack working into a pinion at the end of a train of gearing, the first motion of which was a screw-and-worm wheel. By means of this gearing the power of the men was communicated to the gate through the beam or stay just described."

After the engineer has succeeded in designing a dock which is sufficient in so far as the sea is concerned, it may often all not prove safe and convenient if it be exposed fully to the force of the wind, which, acting on the rigging and hulls of the shipping, causes vessels to break their moorings or produces a grinding action of the vessels against the quays. At Sunderland south dock and at the docks in the Tyne, for example, the gales of October 1863 occasioned very considerable damage, from vessels breaking adrift from their moorings and coming into collision with other vessels.

Docks should be sheltered from wind.

Capacity of docks and harbours for trade.

The number of vessels that can be accommodated in each acre of a harbour may be termed its "available capacity." This most obviously vary with the sizes of the craft which frequent the port and with the ratio of sheltered to unsheltered acreage; or in other words, with the exposure, depth, and reductive power. It will therefore be highest for a dock with gates, less for a tide-basin into which the waves have access, and least of all for an anchorage breakwater or roadstead. But it also depends on the form of the basin and on its depth.

The following table contains the greatest number of vessels that can be accommodated at one time per acre for several docks:—

Name.	Tonnage of Vessels.	Number of Vessels per Acre.	Authority.
Androssen.....	100 to 1000	16	Mr Moffat, C.E.
Avonmouth.....	2000	0.75	Mr Huxford, C.E.
King's Lynn.....	1500 aver.	6	Do.
Silloth.....	60 to 800	7.50	Mr Boyd, C.E.

If n represents the number of vessels per acre, and t their average tonnage, and a is a coefficient which may be taken at from 3 to 4 according to the tonnage inversely, the formula $n = \frac{1000}{t \cdot a}$

may perhaps be convenient for showing, though necessarily in a very approximate way, the relative capacity for mixed shipping of proposed docks of symmetrical proportions. But the capacity will very largely depend on whether both large and small vessels frequent the port, or only vessels of one size.

The capacity for tonnage per acre is shown in the following table:—

Name.	Depth of Water in Feet.	Tonnage per Acre at one time.	Tonnage shipped and unshipped per Acre per annum.	Authority.
Androssen.....	18½	8400	90,000	Mr Moffat.
Delfaat.....	22	8074	40,807	Mr Rahmond.
King's Lynn.....	25	9000	22,650	Mr Bransless.
Silloth.....	22	6000	40,718	Mr Boyd.

The general form of a dock will in most cases be dependent on local peculiarities. Where the nature of the ground counts, and other circumstances admit of it, the width of the basin should, in order to provide for the largest amount of traffic, be greater near the entrance than at a distance from it.

The diagram (Fig. 8) may perhaps be regarded as an approach to the form of maximum capacity which should be kept in view as a general guide in making a design. But in most situations the form will, as we have said, be mainly if not entirely dependent on the outline of the land and depth of water, on the position of adjoining streets and buildings, and on the geological formation and nature of the subsoil. The sketched outline of the jetty shown in the diagram affords a larger amount of accommodation for

Fig. 8.

shipping than when the quays are continuously straight. Sir John Hawkshaw was, we believe, the first to adopt these indented jetties, which are specially suited for the coal trade; but the radiating form shown in the diagram has not, so far as we know, been adopted. Not only are numerous cross sections of the ground required for fixing on the best site for a dock, but borings of the subsoil are essential, as, upon a careful comparison of these, the position of the entrances must be determined. It is always of the greatest importance to place the foundations of the lock or entrance gates at a place where the bottom is rock; or, where that is not to be found, on the hardest and most impervious part of the subsoil, or, failing that, on a place where the bottom—though soft, is of uniform consistency.

Mr. Uie, in a report on Glasgow harbour, gives the following table showing the amount of work per yard per annum —

Port	Turnage per Yard of Quay	Damage per Yard of Quay	Remarks
Glasgow, including steamers	30,670	410	Fully worked
Glasgow, excluding steamers	30,361	393	
Southampton Tidal Harbour	20,000	370	Could do more
Liverpool Docks	21,500	185	Fully worked
Hull Docks	19,000	143	During months
St Catherine's Docks	20,500	142	Fully worked

A great increase in the amount of trade, with the same size of dock and length of quay, may be effected by Sir William Armstrong's patent hydraulic machinery. This principle of applying hydraulic pressure for opening gates, bridges, and sluices, or to the capstans for hauling vessels out for floating them on the turntables, the discharging of ballast and loading of coals, and the shipment and discharging of general cargoes, has now been successfully adopted at many harbours. Its use is, however, only warrantable where there is a great amount of traffic, and especially at places where the spring tides remain only a short time at the same level.

At the Victoria Docks, London, the late Sir Biddler mentions that 41 craft and 17 ships, or 11,711 tons, came in at one tide. In one month the number of craft entering the harbour was 1299, craft leaving, 1288, ships entering, 250, ships leaving, 258, or an average of 2817 craft and 608 ships during the month. The quays, which are 80 feet apart, are opened in less than 14 minutes. At Sunderland the accumulators are equivalent to a head of 600 feet, and the engine is 80 horse power. A wrought iron bridge 18 feet wide, and including counterweights equal to nearly 200 tons, is raised vertically 18 inches, and drawn back in about 2½ minutes. At Swansea the accumulators are equivalent to an effective pressure of 750 lb per square inch, and there are three high pressure engines of 80, 80, and 12 horse power respectively. The time employed in raising and closing the gates is about 3½ minutes, which is the time taken to open the gates with safety. The wrought iron swing bridge can be opened or shut in 11 minutes. The ballast cranes, which are distributed round the dock, can each discharge from 550 to 600 tons in the day. The quantity of coal that can be shipped is about 1000 tons per day, and the effective quantity of water required for the port is 21,050 cubic feet per week. The long narrow basins at Leith, designed by Messrs Rendel & Robertson, and worked by the Armstrong apparatus, are 120 feet square, — length of quays 214 feet, weight moved 750 tons, — and are opened in 11 minutes. The saving of time effected by this method is very great, for at Liverpool, according to Mr. A. Giles, gates of 70 feet require 20 minutes, and six men on each side to open them.

The proportion of water area to length of quays will obviously depend on the form of the docks. The following table, deduced from information kindly supplied by Mr. Lyster O.E., gives examples on this head at Liverpool —

Total Water Area and Quay Space at Liverpool and Birkenhead

	Water Area		Length Quayage		Length Yards at Quay per Acre	
	Acre	Yards	Miles	Yards	Yards	
Liverpool Docks	252	1801	17	1172	1214	4
Liverpool Basins	16	4441	1	1088	168	8
Liverpool Docks & Basins	268	1992	18	1280	1382	7
Birkenhead Docks	150	4685	9	110	99	7
" Docks and Basins	164	2638	9	770	101	0

In order to utilize the area of a dock to the best advantage, a certain amount of land space dependent on the kind of trade should be provided around it, for without this space, which is needed for giving room for railway sidings, ware houses, and the like, the traffic would be cramped. As an illustration of the large extent of railway which is required in a coal port, we may refer to Cardiff, where Mr. McConnochie says, "The extent of sidings provided and maintained by

the Rate trustees, in connexion with the docks, amounts to 16 miles in length, the whole of which is at times fully occupied."

The proportion of the area of outlet basin to that of Proper dock to which it forms the access varies necessarily with the requirements of the trade, as is shown in the following table —

	Dock	Outlet Basin	Ratio
Bute Dock (East)	42 58	2 15	19 60 1
Bute Dock (West)	16 58	1 40	12 04 1
North Dock	17 11	2 08	6 30 1
Tyne Dock	50	9 50	6 27 1
Liverpool generally	107	13	8 23 1

The level of the bottom of a dock is always kept lower or deeper than that of the sill of the entrance gate, in order to admit of a certain amount of deposit taking place without unduly affecting the depth of water in which the vessels lie, or interfering with the working of the gates. These should never be less than 1 foot of greater depth over the bottom of the dock than over the entrance sill.

The commercial advantage of a great depth of water over the sill has been well shown by Mr. George Robertson in his report on the Albert Dock at Leith. By increasing the depth to the extent of 2 feet he found there would be 396 tides in the year giving a depth of 23 feet over the sill, as against only 102 tides in the year when that depth could be had if the sill were only 2 feet high. But besides the advantage of saving cargoes of a greater number of tides, Mr. T. Stevenson found, from an examination of the draughts and tonnage of a large number of sailing vessels, that the commercial advantages in a navigable river, dock, or harbour are proportional to the cubes of the depth.

The relation subsisting between the depth of a dock or channel and the tonnage of sailing vessels which can use it is given by the formula $t = 13d^3$, or $d = \sqrt[3]{\frac{t}{13}}$, from which the following table has been calculated —

Feet	Tons	Feet	Tons	Feet	Tons
5	10	12	225	19	872
6	23	13	286	20	1016
7	41.5	14	367	21	1201
8	66.5	15	450	22	1418
9	98	16	533	23	1661
10	130	17	639	24	1797
11	173	18	768	25	2011

In fixing the minimum width that will admit vessels of the size which are expected to trade at the harbour, the engineer must take care to preserve a proper relation between the area of the dock and the width of the entrance, for if this relation be neglected, a current may be generated through the entrance when the tide begins to ebb, which would be incompatible with the safe working of the gates. A very small current is sufficient to act injuriously in this way, especially if the gates be of great width. Whenever the internal area of the proposed basin is considerable, it will be a safe precaution to calculate the velocity of the outgoing current, at different periods of time, after the tide has begun to ebb, and for this purpose observations of the fall of the tide must be carefully made and compared with the proposed transverse sectional area of the passage through the lock chamber. If the velocity thus obtained be thought too great for the safe working of gates of the size required, the only alternative is to provide an additional lock. But a double outlet will at any rate be in all probability needed, or will at least prove a great convenience in all cases where a large internal basin is required.

Lockage. The late Dr Rankine in his *Manual of Civil Engineering* gives the following table for the expenditure of water due to the passage of vessels through the lock —

Let L denote a lockful of water, that is, the volume contained in the lock chamber between the upper and lower water levels, and B the volume displaced by a ship, then the quantity of water discharged from the dock, as shown in the table. The sign prefixed to a quantity of water denotes that it is displaced from the lock into the dock.

Single Lock	Lock in tand	Water Discharged	Lock in tand
A descending ship	1 ship	$L - B$	1 ship
Do	2 ships	$L - B$	1 ship
An ascending ship	1 ship	$L + B$	1 ship
Two ships ascending, and ascending alternately	2 ships	$L + B$	1 ship
Two of a ship descending	1 ship	$L - B$	1 ship
Do	2 ships	$L - B$	1 ship
From a ship ascending	1 ship	$L + B$	1 ship
Two of a ship ascending	2 ships	$L + B$	1 ship
Descending ship, at ascending	1 ship	$L + B$	1 ship

From these calculations it appears that ships ascending and descending alternately cause less expenditure of water than equal numbers of ships in tandem.

Depression
of
dock-
level

The level of the surface of the water in a dock will of course sink in proportion to the number of times the lock has to be filled during each tide, and may also be affected to a small extent by leakage. In order to provide for this depression of level, the old dock of Gimsby, and also the Duke Dock, Cardiff, are supplied by lead steamers, while at Fenchurch St. John Hawkwood was unable to get a supply of pure water, and the dock at that port is supplied from the tide water of the Bristol Channel, which holds in suspension a large amount of alluvial matter. In the old London docks the level is kept up by pumping.

If the masonry of the walls has been properly constructed, and if the gates and lock are kept in proper repair, and especially if the basin be of large area, the depression of the water level due to leakage, will, as appears from the following table, be comparatively trifling —

Name of Dock	Area in Acres	Leakage	Author's Estimate
Aldershot	1	18 in per tide	Mr Moffat, C E
Bilfast	32	At first 1 to 2 in, now 6 in springs, and 4 in drains	Mr Selmond, C E
Whitehaven	44	8 in	Mr Dumbleton, C E
Avonmouth	16	1 in in 24 hours	Do
Krug's Lynn Sulphur	6	1 in	Mr Boyd, C E

Works
of
con-
struction

The principal works required in the construction of docks are—*first*, cofferdams for excluding the tide, and pumps for keeping the basin dry while the works are going on; *second*, excavation of the basin and lock pit, *third*, piling for the foundations of quay walls and lock, where the bottom is soft, *fourth*, the building of the quay walls, lock, and outer tide basin, *fifth*, entrance gates, gateway, and dolphins in the channel outside of the dock for facilitating the entry and departure of vessels.

As to the *first* of these works, namely, the cofferdam and pumping apparatus, reference is made to the articles on these subjects in this work, and as to the *second* and *third*, there is nothing requiring special notice, as no peculiarities attaches to the mode of carrying on excavation or piling for docks more than for any other engineering undertaking where these are needed. It is only necessary to point out that when the bottom is soft a large amount of piling is required, more especially at the lock pit, where rows of sheeting piles should be driven across the lock, at least at the entrance, and in the lines of the clep or pointing sill against which the gates shut.

The *fourth* class of works, namely, quays and lock, are in all cases most important features in a dock. Dif-

ference rules have been given by engineers for the proportions of quay walls. Mr A. Gilles recommends that they should be made strong enough to resist the pressure of a head of water equal to their own height, and Minard recommends their thickness at bottom to be $\frac{1}{10}$ ths of their height.

The recent use of Portland cement concrete in the Quay structure of harbours has led to its introduction at dock walls of works. In the small dock erected in 1875 at Borewick on the new Victoria Dock, London, which are the longest in the world, is making the whole masonry of cement concrete.

Graving docks are basins sometimes 600 feet long and 60 or 70 feet wide, fitted with gates, from which the tide water which floats the vessel into the dock is pumped out, so as to let the carpenter get access to the ship's bottom. The sides of graving docks consist of a series of steps of masonry, called "altars," against which small timber props, generally of Gulf of Botania timber, are placed, for supporting the vessel's sides as she ceases to be water-borne. Her keel is supported on blocks, generally of hard wood, but of late years they have in some places been made of cast iron. The sides, in order to save pumping, are in some places made of a curved form, so as to suit the shape of the vessel's side. The altars are, however, more than counterbalanced by the undue contraction of the space allotted for the carpenter, who is unable to move about easily on the sloping surface of the masonry.

Of all the different kinds of masonry which enter into the construction of marine works, there is none which requires greater accuracy of workmanship, or more careful supervision, than the graving dock. Leakage in a wet dock, provided it does not originate at a place where it is liable to increase through time, and is of no greater extent than to depress the surface of the water a few inches, cannot be regarded as a serious evil. But in a graving dock, where the requirements are different, there should be no leakage. A very little water, accumulating on the platform of a dry dock, interferes to a serious extent with the comfort and convenience of the carpenters. Although it may occasion considerable additional expense, there ought to be in all cases, especially where the soil is full of springs, an ample underground storage provided by a system of drains for receiving the leakage, which can then be pumped out periodically, as required, without ever allowing the water to rise above the platform.

Mr G B Rennie's docks are stated to be the first of the kind that have been made of iron. They consist of floating caissons for holding the vessel to be repaired. They are sunk by allowing them to fill with water, and are raised by pumping. The caissons are made with water tight compartments, and they are carried up as high as the vessel's bulwarks, excepting that through which the vessel enters and leaves. Among several advantages that have been claimed for this kind of dock may be mentioned—its independence of the rise and fall of the tide, the power of applying breast shores as in an ordinary graving dock, and the stiffness produced by the side walls. As the upper parts of the side walls or altars are always full of air, this dock may be used in deep water, and is therefore independent of the nature of the bottom.

Mr Edwin Clark's hydraulic lift, at the Victoria Dock, London, consists of a pontoon which is filled with water, and is sunk between two rows of iron columns. After a vessel has been floated and stowed upon the pontoon, the whole is raised by twelve hydraulic force-pumps of 2 foot diameter, acting on the pontoon by means of chains. After the

Mr G
Clark's
hydraulic
lift

pontoon has been thought about the tide level, the water is allowed to creep, when there is sufficient floating power to admit of the whole being removed to any place where the repairs can be conveniently made. The pontoons, which can accommodate vessels of a length of 350 feet, are about 320 feet long and 59½ feet broad. "The power of the hydraulic lift is 6400 tons. The largest pontoon will carry a dead load of 9200 tons in addition to its own weight."

Ships

Ships as the contrivance of the late Mr. Thomas Motton of Leith, and consist of a carriage or cradle working on an inclined railway, falling generally at the rate of about 1 in 17, and extending above high water to a sufficient distance for the class of vessels which are expected to use them to several feet below the level of low water, and a truck or carriage which moves on it. When the carriage is let down under the water, the vessel is floated above the place, and the carriage is drawn up till the vessel catches it forwards. When the ship is placed truly above the line of the carriage, a powerful crab purchase at the top of the ship, which is generally worked by steam, is set in motion, and raises the truck and ship out of the water.

Tidraoon

The tidraoon is a simple framework of timber placed at a level sufficient to admit of vessels being floated above it during the flood-tide, and grounded upon it during the ebb, and when thus left high and dry the vessels bottom can be examined to ascertain if it be necessary to take her into the graving dock, and fitting repairs can also be made. The tidraoons at Liverpool vary from 26 feet to 36 feet 3 inches in breadth, and from 228 feet 3 inches to 313½ feet in length 1.

Hydraulic and screw docks

The hydraulic and screw docks used in America are chambers into which vessels are floated during the flood-tide, above a cradle which is drawn up above the high water level, either by means of Dumas's press worked by a steam-engine, or by a powerful apparatus of screws.

Relative advantages in ships and graving docks

The patent ship possesses the following advantages over the graving dock: (1) The cost of its construction is less. (2) When the full tide is longed, a vessel can generally be more quickly laid dry. (3) When so laid dry she can be more easily examined, and, from the duration of the daylight being greater than in a deep graving dock, the time in which work can be done is considerably extended during winter. (4) There is more perfect ventilation, by which the vessel's sides are sooner dried, which is of some moment with iron ship. (5) A vessel can be hauled up long before high water, and the repairs can be begun at once, whereas with a dock the pumping occasions considerable delay. (6) While the upper part of the ship is occupied, an additional vessel may be taken up for a shorter time than the predecessor, without interrupting the workmen.

The advantages afforded by a graving dock, on the other hand, are these: (1) Although its construction is more costly, it is nevertheless, if properly built, unquestionably a more durable structure—the rails, rollers, carriages, and chains connected with the ship being liable to derangement, which entails occasional repairs. (2) The management of the graving dock is simple, and involves comparatively little superintendence, whereas that of a ship is intricate, and requires more than mere nautical skill. (3) The working of a graving dock is equally simple for large or small vessels, while it is undeniably that the raising of a large vessel on a ship is a delicate operation, and should be attempted only under the direction of persons thoroughly versed in such matters, and having ample mechanical resources at command. (4) The graving dock possesses the advantage, which is sometimes important, of affording the means of more easily filling a vessel with water, so as to detect leaks which may not be discoverable by other means. For this purpose a

1. "Historical and Descriptive Sketch of the Mersey Docks and Harbours," by J. J. Runkel, in the *Astoria* for 1864.

pump to receive a flexible tube should be fixed into the dock gates. (5) Where double gates are provided the water contained in the dock affords a certain limited power of scouring the forebay and entrance, an advantage which is of course not possessed by a slip. (6) In any rapid land current, or strong tide-way, it is a much easier process to dock a vessel than to land her safely on the cradle of a slip—an operation which, when incautiously gone about, has been in some cases attended with serious consequences even in sheltered situations. (7) The graving dock need not interfere with the set of the currents, whereas a slip which projects a long way seaward of low water may deflect them and produce shoals in the channel. (8) Mr. Mallet has remarked that the strains on a ship's timbers are more direct than when she is on a slip, especially when she is leaving the cradle. The late Mr. J. M. Balfour suggested, in order to meet this objection, that the cradle for a ship might be made of a wedge shape, so that its upper surface shall be parallel with the horizon, or that the back and should even be tilted slightly, so as to give a lute on this vessel and prevent her from slipping.

The relative advantages of the other contrivances for the repair of ships already described may be judged of by comparing them with each other in a similar manner.

Mr P. W. Barlow has given the following formulae for Dock strength of dock-gates—

Formulae for Straight Gates

If ϕ = horizontal angle (or "sally") between a pointing sill and line joining heel posts of the two leaves, W = pressure on the height of the gate with any head, and for a given depth of the gate, and S = hole transverse strain at angle ϕ , then

$$S = 1\frac{1}{2} W \sin \phi + \frac{1}{2} W \cos \phi$$

From this Mr. Barlow has deduced that the safest angle, where the strain is the minimum, is $24^\circ 54'$, but as the length of the gate increases with the sally, the strength will rise at this angle, be the greatest with a given section of timber. The "sally" or angle which gives the greatest strength, with a given section of timber, is stated by him as $16^\circ 28'$.

Formulae for Curved Gates

When θ is the volute angle, or (radius of the beam, formed by a chord line drawn from the heel to the mitre post, with the tangent to the curve of the gate)—

$$S = 1\frac{1}{2} W \left\{ 1 - \frac{\sin \theta}{\sin (\frac{1}{2}\theta - \theta)} \right\}$$

There is great difference of opinion among engineers as to the strain to which dock gates are subjected, and it is not intended to furnish information to the 18th and 19th volumes of the *Annals of the Institution of Civil Engineers*. In these two volumes Mr. Brown pointed out an error in Mr. P. W. Barlow's paper, which stated that the line of pressure at the mitre posts would always be tangent to the curve of the mitre post gates, whereas that line must always be at right angles to the centre line of the lock, and could only be tangent to the curve when the two gates formed a segment of a circle, or, as Mr. Brown says, "at all events when that junction at the mitre posts formed at that point part of a continuous curve. Mr. Brown gives a formula for the strain to meet a yielding or deflection of the same time, which he alleges must always take place. Mr. Brown's view, and we think justly, that when the gates form when closed a segment of a circle, they cannot be subject to transverse strain, and that the whole of the gates would be subjected simply to compression. Mr. R. P. Brierley very properly suggests that when the gates are of multiple arcs the boiler plate should never be less than 7 in thick, what, even the formula may indicate.

Where l represents the length of one half of a straight or circular malleable iron gate, so the distended pressure over the length of the leaf taken on a given element of the gate, bounded by two horizontal planes 1 foot apart, s the thickness of the framework of gate or distance between the two skins, t the transverse strain in middle of gate, θ half of the mitre angle—i.e., the angle formed by meeting of gates—all the dimensions being in feet, and weight in tons, then

$$s = \frac{l^2 \sqrt{t}}{4t}$$

$\frac{1}{2}$ s = sectional area of metal on compressed side in inches,
 t = do do on distended side do
 $\frac{1}{4}$ wt ton = compressive strain produced by effect leaf of gate

CARDIFF DOCKS
CAISSON FOR GRAVING DOCK

SCALE: 1/4" = 1' 0"

HARBURG, a seaport town of Hanover, Prussia, at the head of a cude in the district of Lüneburg. It is situated on the left bank of the southern branch of the Elbe opposite Hamburg, which stands on the right bank of the northern branch of that river. The distance between the two towns is about 4½ miles, and there is railway communication between them by means of a bridge over both rivers, completed in 1871. The town is also connected with Hanover by railway. It is the seat of a local court, a superintendent-general, a head custom house, and a chamber of commerce, and it possesses an old castle, which from 1624–1642 was the residence of the Hamburg line of the house of Lüneburg, a real-school of the first order, a commercial school, and a trade school. The industries include shipbuilding and the manufacture of india rubber and gutta percha wares, oil, soda, starch, alum, ovens, yarn, cast-iron, machines, and leather. There are also houses and cattle markets, and some shipping trade, which, however, has considerably declined since better communication was opened up with Hamburg. In 1878 there entered 469 sea-going vessels with a burthen of 38,110 tons, and 7677 non-vessels with a burthen of 175,643, while the corresponding averages during the previous twelve years (1866–1877) were 633 sea-going vessels and 7669 of non-craft, with burthens respectively of 43,036 and 168,082 tons. Harburg belonged originally to the bishopric of Bremen, and received town rights in 1307. In 1374 it was united to the principality of Lüneburg, along with which it fell in 1705 to Hanover, and in 1806 to Prussia. In 1813 and 1814 it suffered considerably from the French, who then held Hamburg, and who built a bridge between the two towns, which remained standing till 1816. The population in 1875 was 17,131.

HARDENBERG, FRIEDRICH VON (1772–1801), German poet and philosopher, best known as Novalis, was born on his father's estate in the county of Mansfeld, in Prussian Saxony, May 2, 1772. He was of a shy, retiring, and thoughtful disposition, and was deeply influenced by his parents, who were strict members of the sect of Moravian Brethren. After attending the gymnasium of Eisleben he went as a youth of eighteen to the university of Jena, where he studied philosophy, mathematics, and the natural sciences. There he was treated with great kindness by Schiller, of whom he was a warm admirer. He studied law in Leipzig and Wittenberg, and in 1791 settled for a time in Tennstedt in order to perfect himself in the practical work of the legal profession. During his residence in Tennstedt he formed a passionate attachment to Sophie von Kuhn, a beautiful but delicate girl of thirteen, and with her consent obtained promises from her parents that when she reached womanhood she should become his wife. In 1795 he was made auditor at the salt works of Wessensfeld, where his father was director. Two years afterwards his betrothed died, and for some time he seemed to be broken-hearted and to have lost all interest in life. In a few months, however, he went to the academy of mines at Freiberg, where he studied with a view to a higher appointment in connexion with the salt-works, and in the midst of his studies he became engaged for a second time, and was again able to look forward to a happy and useful career. He returned to Wessensfeld in 1799, and was associated as assessor with the directorate of the salt-works. As he was preparing for his marriage in the autumn of 1800 he was alarmed by the sudden appearance of blood from the lungs. The wedding was postponed, and although he believed to the end that his recovery was certain, the disease made rapid progress, and he died on the 25th of March 1801. He was of a tall, slight, and graceful figure, with light brown hair and hazel eyes, and a face expressive of a calm, gentle, and meditative spirit. After his death his

writings were issued in two volumes by his friends Ludwig Tieck and Friedrich Schlegel, and were rapidly recognized as important contributions to German literature. They are for the most part composed of fragments, of which the chief is *Heinrich von Ofterdingen*, an unfinished romance. Hardenberg is often spoken of as "the prophet of the Romantic school," and the phrase sufficiently marks his leading peculiarities. He took no part in the literary warfare carried on by his friends, but he adhered to the full their strongest sympathies. Like them he intensely disliked those "enlightened" writers of the 18th century who had claimed to say the last word about human life through mere logic, he was penetrated by the conviction that there are elements in the world which cannot be grasped by the understanding, and which must be felt rather than reasoned about. Although he was fond of science and history, he moved most freely in the borderland between religion, philosophy, and poetry, and his prose writings are full of sayings which, although not easily intelligible, are impressive and stimulating. His diction is often simple and unostentatious, but it is rendered difficult both by the abstruseness of his themes and the remoteness of his allusions. As a poet he lacked definiteness of conception, his lyrics, however, especially those of a religious nature, have a certain tender beauty which gives them high rank in the serious literature of Germany. They are marked by deep feeling and by sweetness and grace of expression. He himself regarded a series of *Hymns to Night* as his best achievement, but it is in *Heinrich von Ofterdingen* that the majority of his admirers find the fullest utterance of his mystic aspirations, his passion for spiritual beauty, and his idealist philosophy.

See his *Schriften* (6th ed., Berlin, 1837, vol. iii., 1840), and H. Rym, *Das Romantische Schulte* (1870), and F. Fiedich von Henckeburg (1878).

HARDENBERG, KARL AUGUST (1750–1822), Prussian statesman, was born at Eisleben in Hanover, May 31, 1750. Having studied at Leipzig and Göttingen, he entered the Hanoverian civil service as chamber councillor (Kammerrath) in 1770, and afterwards spent some time in Vienna, Batschon, Vienna, and Berlin, and travelled in France, Holland, and England. He was made privy chamber councillor (Geheim Kammerrath), and raised to the rank of count in 1778, but a private quarrel with the prince of Walos compelled him four years afterwards to give up his appointments in Hanover and seek a new career. In 1787 he received the office of president of the board of domains (Kammercollegium) in Brunswick, and he was entrusted with the duty of delivering to Frederick William II of Prussia the will of Frederick the Great, who had deposited it with the duke of Brunswick. Frederick William II. was so impressed by Hardenberg's appearance and character that he recommended him as a minister to the margrave of Anspach and Bayreuth. These principles were sent unaltered to Prussia in 1791, Hardenberg was appointed a Prussian cabinet minister, but continued to perform his duties as chief administrator of the new province. In the war with the French republic he acted as minister of war, and in 1795 signed on behalf of Prussia the treaty of peace concluded at Basel. When Frederick William III. mounted the throne in 1797, Hardenberg was transferred from Anspach-Bayreuth to Berlin, where he received high offices in the cabinet, being also soon afterwards nominated chief of the departments for Magdeburg and Halberstadt, for Westphalia, and for Neuchâtel. At this time the foreign policy of Prussia was determined by Jürgwitz, who was on all occasions subservient to Napoleon. When in 1803 Prussian interests seemed to be threatened by the French occupation of Hanover, Jürgwitz fell into disrepute, and in the following year his place at the head of the cabinet was

taken by Hardenberg. The latter was anxious to maintain peace, but when in 1805 Napoleon's troops marched through Anspach he strongly protested, and entered into a convention with Russia. The victory of the French at Austerlitz, however, made it difficult for Prussia to proceed to hostilities, and on the 15th December 1805 Haugwitz signed a convention with Napoleon, whereby in return for Hanover Prussia conceded Anspach, Cleves, and Neuchâtel to the French. Hardenberg then retired, and Haugwitz returned to power. The policy of Haugwitz was exceedingly unpopular, and led to the loss in which his country was prostrated at the feet of Napoleon. After the battle of Jena Hardenberg undertook the office of foreign minister, but when the treaty of Tilsit was signed he withdrew and watched from a distance the vigorous and enlightened efforts of Stein to restore new life to the fallen and humiliated state. Stein being compelled to retire in 1810, Hardenberg was recognized as the only possible successor of the great minister, and he amply justified the confidence with which he was honoured. The circumstances of the time did not admit of his pursuing an independent foreign policy, but he steadily prepared for the inevitable struggle with France by carrying out Stein's far-reaching schemes of social and political reorganization. The military system was completely reformed, so that was established, municipal institutions were fostered, the civil service was thrown open to all classes, and great attention was devoted to the educational needs of every section of the community. In the war of liberation Hardenberg was one of those who did most to stimulate the patriotic enthusiasm not only of the Prussians but of all Germans, and so important were his services that on the 3d June 1813, after he had signed the first treaty of Paris, he was raised to the rank of a Prince or Prince. He accompanied the allied sovereigns to London, was one of the chief plenipotentiaries at the congress of Vienna, and took a leading part in the negotiations which led to the second treaty of Paris. After the restoration of peace he retained his place at the head of the Prussian cabinet, but his conduct of affairs was no longer marked by energy and foresight. He was accused of being too submissive to the papacy, and, although a man of liberal sentiments, he had not the courage to resist his royal master's dislike of constitutional government. He died at Genoa, November 26, 1832.

Hardenberg wrote memoirs of the time between 1801 and the conclusion of the treaty of Tilsit, and carried them before his death to his friend Schell, a counsellor of state. They were seized by Friedrich Wilhelm III and placed in the state archives, with directions that they should not be published until after the lapse of fifty years. At the end of that time they were edited by F. von Hinrich, to Leopold von Ranke, who revised them according to a biography of the author (*Denkmal des Staatskanzlers Fürsten von Hardenberg*, 1 vol., 1877). See also Klein, *Leben Karls Augusts, Fürsten von Hardenberg*, 1851, and Becker, *Life and Times of Stein*, 1879.

HARDERWIJK, a town of the Netherlands, in the province of Guelderland, on the coast of the Zuider Zee, about 28 miles N E of Utrecht. Its principal buildings are the town-house, the Reformed church rebuilt in the 15th century, the Nassau-Verlve gymnasium, the colonial dockyard depot, formerly the mint, and the municipal orphanage. Agriculture, fishing, and a few tanning domestic industries form the sole employment of the inhabitants, who in 1872 numbered 5041.

Formerly the town was much more important. Having been surrounded with walls by Count Otto II in 1220, and gifted with municipal privileges in 1321, Harderwijk rapidly extended its commerce till at last directly not only with Lorient and Hamburg but with England, Denmark, and Sweden. In 1592 the town was captured by Charles V., in 1672 it became subject to the United Netherlands, and in 1678-79 it was besieged for seventeen months by the bishop of Münster and his French allies.

HARDICANUTE, **HARTECANUT**, or **HARDKNUT** (c. 1018-1019), the last of the Danish sovereigns of England, son of Canute king of England, and his wife Alfgiva Emma, the sister of Richard duke of Normandy, and widow of King Ethelred, was born most probably in 1018 or 1019. When Canute died in 1035 Hardicnut was ruler of Denmark, and Swend, the elder reputed son of Canute by Alfgiva of Northampton, one of his concubines, was ruler of Norway. It is said to have been the wish of his father that Hardicnut should be ruler of both England and Denmark, but his connexion with Denmark seems to have been prejudicial to his English interests, and though his claims were supported by Godwine and the West Saxons, the witenagemot which met at Oxford decided that his government should not extend further north than the Thames, and that Harold, Canute's younger son by Alfgiva of Northampton, should reign over the northern provinces, being also in all probability overlord of the whole kingdom. Hardicnut refused, however, to come to England on such conditions, and in 1039 the witan of Wessex deposed him, and chose Harold also for their king. On the death of Harold in 1040, Hardicnut, who was about to invade England, had his hostile intentions dissuaded by the message which reached him at Bruges, making him an offer of the crown on which he was preparing to land. The terms of the offer of him seems to have been spontaneous, and not at all due to the threatening attitude he had assumed, but apparently he had not forgotten the former slight he had received, and his abjuration was marked by great opposition and civility. He caused the dead body of Harold to be dug up from its place of sepulture at Westminster, and thrown into a marsh or, according to another account, into the Thames, he exacted so heavy a *danegeld* for the support of his foreign fleet that great discontent was excited throughout the kingdom, and in Worcester a general uprising took place against the sails sent to collect the tax, upon which he burned the city of Worcester to the ground and devastated the surrounding country, in 1041 he permitted Knutolf, earl of Northumbria, to be treacherously murdered after having granted him his full friendship. It would appear that Hardicnut was greatly given to excess in eating and drinking, and while carousing at the marriage feast of one of his nephews he was suddenly seized with an epileptic fit, from which he died a few days afterwards, June 8, 1042. He had no children, and though the line of Danish sovereigns might have been continued by Swend, the choice of the kingdom was unanimous for Edward Atheling, son of Ethelred.

HARDING, JAMES DWYFIELD (1798-1868), a landscape painter, was the son of an artist, and took to the same vocation at an early age, although he had originally been destined for the law. He was in the main a water-colour painter, but he produced various oil-paintings both at the beginning and towards the end of his career. He frequently contributed to the exhibitions of the Water Colour Society, of which he became an associate in 1818, and a full member in 1829. He was also very largely engaged in teaching, and published several books developing his views of art,—amongst others, *The Tourist in Italy*, 1831, *The Tourist in France*, 1834, *The Park and the Forest*, 1811, *The Principles and the Practice of Art*, 1845, *Elementary Art*, 1840, *Scotland delineated in a Series of Views*, 1847, *Lectures on Art*, 1849. He died at Barnes on 4th December 1868. Harding was noted for facility, sureness of hand, nicety of touch, and the various qualities which go to make up an elegant, highly trained, and accomplished sketcher from nature, and composer of picturesque landscape material, he was particularly skilful in the treatment of

foliage, and had for many years a leading position among those landscapeists who carry on the miscellaneous work of the art to the satisfaction of their own generation, without establishing an ultimate claim to the higher kind of posthumous renown.

HARDING, JOHN See HARDYNG

HARDINGE, HENRY HARDINGE, VISCOUNT (1785–1856), field marshal and governor general of India, was born at Wrotham in Kent, March 30, 1785. After passing a short time at Eton college, he entered the army in 1798 as an ensign in the Queen's Rangers, with whom he served in Canada. In the Peninsular War he served for a time on Wellington's staff, and received an appointment as deputy-quartermaster-general in the Portuguese army from Marshal Beresford, whose approval and subsequent influence he had won by his gallantry at Corunna in 1809. Hardinge was present at nearly all the battles of the campaign, he was wounded at Vimiera and Vittoria. At Albuera he saved the day for the British by taking the responsibility at a critical moment of ordering General Cole's division to advance. When peace was again broken in 1815 by Napoleon's escape from Elba, Hardinge hastened into active service, and was appointed to the important post of commander at the Prussian headquarters. In this capacity he was present at the battle of Ligny, June 16, 1815, where he lost his left hand by a shot, and thus was not present at Waterloo fought two days later. For the loss of his hand he received a pension of £300, and in the same year was made a K C B. In 1820 and 1826 Sir Henry Hardinge was returned to parliament as member for Durham, and in 1828 he accepted the office of secretary at war in Wellington's ministry, a post which he also filled in Peel's cabinet in 1841–43. In 1830 and 1834 he was chief secretary for Ireland. In 1844 he succeeded Lord Ellenborough as governor general of India, a position which he retained till January 1848. During his term of office the Sikh War broke out, and the governor general after the battle of Mudki magnanimously offered to serve as second in command under Lord Gough. He manifested all his old courage and skill, and at the peace, for his services in the campaign, he was created Viscount Hardinge of Lahore, and of King's Newton in Derbyshire, with a Government pension of £3000 for three lives, while the East India Company voted him an annuity of £5000. He returned to England in 1848, and in 1852 succeeded the duke of Wellington as commander-in-chief of the British army. While in this position he had the home management of the Crimean War, which he endeavored to conduct on Wellington's principles—a system not altogether suited to the changed mode of warfare. In 1855 he was promoted to the rank of field-marshal. Viscount Hardinge resigned his office of commander-in-chief in July 1856 owing to failing health, and died on September 24th of the same year at his house near Tunbridge Wells.

HARDOL, a British district of Oudh, India, under the jurisdiction of the lieutenant-governor of the North Western Provinces, lying between 26° 53' and 27° 47' N lat., and between 79° 44' and 80° 52' E long., with an area in 1878 of 2335.64 square miles. The district is an irregular parallelogram between the Gumti and Ganges, its greatest length from north-west to south east is 75 miles, and the average breadth is 46 miles. It is bounded on the N by Shahjahanpur and Kheri, E by Sitapur, the Gumti forming the boundary-line, S by Lucknow and Unao, and W by Farrukhabad, the Ganges marking the boundary. It is a level district watered by the Ganges, Rámangga, Garra, Sukhetá, Sáti, Baita, and Gumti,—the three rivers first named being navigable by boats of 500 *mauvais*, or about 17 tons burden. Towards the Ganges, the land is uneven, and often rises into hillocks of sand cultivated at

the base, and their slopes covered with leafy *misri* grass. The soil of Hardol is lighter than that of pollyany, any other district of Oudh, 27 per cent being sand, 66 per cent loam, and 17 per cent clay. Several large *jháls* or lakes are scattered throughout the district, the largest being that of Sándi, which is 3 miles long by from 1 to 2 miles broad. These *jháls* are largely used for irrigation, 126,000 acres being watered from them. Large tracts of forest jungle still exist. Leopards, black buck, spotted deer, and *nilgáys* are common, the mallard, teal, grey duck, common goose, and all kinds of waterfowl abound.

The inhabitants of Hardol district in 1869 numbered 931,517, of whom 500,994 were males and 430,523 females (Hindus, 816,263, Mahomedans, 56,524, Christians, 48, "others," 423). The main *lugat* towns are—Sháhábád, 18,254 inhabitants, Sándi, 15,511, Bilgram, 11,681, Malláwan, 11,670, Sándi, 11,124, Páránt, 7262, Hardol (the administrative headquarters of the district), 1756, Gopáman, 6949, and Báy, 6122. The principal *lugat* fairs are the following—At Bilgram, in September, on the occasion of the *Jám Zila* festival, lasting ten days and attended by about 10,000 persons, at Káitá, Itáran, during the whole month of Húsdá (August and September), attended by 100,000 persons, at Húsdá, in April and November, the *Pranahara Sándi* *féstá* is held for only a single day on each occasion, and attended by from 15,000 to 20,000 persons. These, together with several other smaller fairs, are held for religious purposes, and have no commercial import and export. Rice, wheat, and other food grains form the great staples of agriculture. The area under crops is 844,560 acres of 1419 *annas* under being more than one half the entire area. The Lucknow and Rohilkhand Railway from Lucknow to Shahjahanpur runs through Hardol for a distance of 62 miles. There are also 320 miles of roads and bridged routes, and 73 miles of minor roads, intersecting the district. The principal imports are cotton, wool, and sugar, and European piece goods, the chief exports,—food grains, sugar, tobacco, humped cattle, and hides. The value of the imports in 1875 was £102,953, of the exports, £62,977. The gross revenue of the district in 1875 amounted to £40,958, the expenditure to £18,478. The regular police (1878) consisted of 430 officers and men, costing £8010. The number of schools in 1875 was 112, with 587 pupils. The average rainfall for the twenty years ending 1872 was 32 *annas*. Malária is endemic, cholera, and smallpox are not infrequently prevalent. The first authentic records of Hinduism at Hardol with the Mussulman colonisation. It was occupied by Húyad Sáid Masúd in 1028, but the permanent Muslim occupation did not commence till 1217. Owing to the situation of the district, Hardol formed the scene of many sanguinary battles between the rival Afghan and Mughal empires. Between Bálqán and Bálkh was fought the great battle between Humayun and Sher Sháh, in which the former was utterly defeated. Hardol, along with the rest of Oudh, became British territory under Lord Dalhousie's proclamation of February 1858.

HARDOUN, JFAN, was a classical scholar of the 17th century, at once singularly learned and lamely singular. He was born at Quimper in Brittany in 1646, and died at Paris in 1727. Having acquired a taste for literature in his father's book-shop, he sought and obtained about his sixteenth year admission into the learned society of the Jesuits. In Paris, where he went to study theology, he ultimately became librarian of the Collège Louis le Grand. The life of laborious authorship inaugurated by his edition of Themistius (Paris, 1684), which included no less than thirteen new editions, was continued with wonderful perseverance and success. At the advice of Garnier he undertook to edit the *Natural History* of Pliny for the Delphin series, and five years saw the completion of a task which, in the opinion of Huet, would have taken any ordinary scholar fifty years. His attention having been turned to numismatics as auxiliary to his great editorial labours, he published several learned works in that department, married, however, as almost everything he did was marred, by a determination to be at all his arts different from other interpreters. It is sufficient to mention his *Nomina antiqua populorum et urbium illustrata* (Paris, 1684), *Antiquitates de nummis antiquis coloniensium et munitionibus* (Gerni, 1689), and *Chionographia Vel Test ad vulgares conversiones exadæ et nummis illustrata* (Paris, 1696). By the ecclesiastical authorities Hardoun was appointed to supervise

the *Concilium collectio regni maxime* (Greek and Latin, Paris, 1715, 12 vols.), but he was accused of suppressing important documents, and forgoing in apocryphal matter, and by order of the publisher of Paris the publication of the work was delayed till some of its deficiencies were remedied. It is, however, as the originator of a variety of paradoxical theories that the learned fithos is now best remembered. The most remarkable, contained in his *Chronologie critique par les medailles* (Paris, 1696), was to the effect that, from the discovery of the works of Homer, Herodotus, and Cæsar, the *Natural History* of Pliny, the *Georgica* of Virgil, and the *Statua* and *Epistles* of Horace, all the ancient classics of Greece and Rome were spurious, having been manufactured by monks of the 13th century.

In 1709 Jean Louis de Lamoignon published at Amsterdam an edition of Hædunius's *Opera Selecta*, and though he made many corrections at the author's suggestion, he refused to admit the wholesale cancelling of the passages condemned by the *Jeux de mots*. Details in regard to Hædunius's theories, controversies, and whimsies may be found in Bayle and Morlet, in Lombrose, *Dict. des poëtes historiques*, in Linnæus, *Hist. litt. du règne de Louis XIV.* Dypna, *Bibliographie des auteurs de l'école des jésuites*, Levet, *Biographie des jésuites* (Paris, 1852-57), and, more particularly, Augustus and Alois de Bæcher, *Bibliographie des jésuites du V. Compt. de Jense* (Louvain, 1858).

HARDY, HENRIEMANN VON DRR (1660-1746), Orientalist, descended from an old Dutch family, was born at Melle, in Westphalia, on 15th November, 1660. His father, who was treasurer of the society of Teplenberg, appreciating his son's abilities, gave him a good education at Osnabrück, and sent him afterwards to Jena and Leipzig. Young Hardy, gifted with a quick disposition and a powerful memory, soon gained renown for his fluency in carrying on learned discussions in Latin, but the study of the Oriental languages divided him from all other pursuits, and in no long time he made him self master of Hebrew, Syriac, and Chaldeæ. The duke of Brunswick, hearing of Hardy's fame, appointed him his librarian shortly after the Ottobach had founded at Leipzig a philological society, with the object of determining the sacred text. In 1690 Hardy was called to the chair of Oriental languages at Helmstedt, and his late master was prevailed upon to present to that university his valuable library, of which Hardy was again appointed to take charge in 1702. Seven years later he was named rector of the gymnasium of Mauerburg, a post which he held till his death on 28th of February 1746.

Among his numerous writings, the following deserve mention:—*Asyngrapha Israhelæ actum unguis celorum Virorum*, ad usum usque ultimum 1546, *Byronensis Bibliothecæ Hædunensis scripta selecta*, 1690-91, *Magnam Christianam Constantine Consistum*, 1697, *Libri lingua Fundamentum*, 1694, *Syriaca lingua Fundam. usque*, 1691, *Hebraica Chaldaica*, 1695, *Index in Hebraicis 26. Fundamentis*, 1717, *Enigmatum prima arbo*, 1723. The last is a collection of pieces previously published separately, all of which had been condemned by the church. This republication was ordered to be suppressed. Hardy left a *History of the Hebrew nation* in manuscript, which is preserved in the Helmstedt Museum.

HARDWAR, or HURDWAR, an ancient town of India and place of pilgrimage, in Saharanpur district, North-Western Province, situated on the right bank of the Ganges at the foot of the Siwalik Hills, in 29° 57' 30" N lat., 78° 12' 52" E long. Population (1872), 4800. The town is of great antiquity, and has borne many names. It was originally known as Kapila from the sage Kapila. Hwen Thsang, the Chinese Buddhist pilgrim, in the 7th century A.D. visited a city which he calls Ho-yu-lo, the remains of which still exist at Mayapur, a little to the south of the modern town. Among the ruins are a fort and three temples, decorated with broken stone sculptures. The great object of attraction at present is the Hai-ke-chai-an, or bathing ghât, with the adjoining temple of Gangadwara. The *charan*, or foot-mark of Vishnu, is imprinted on a stone set into the upper wall of the ghât, and forms an object of

special reverence. A great assemblage of people takes place annually, and every twelfth year a feast of peculiar sanctity occurs, known as a *Kumbh mela*. The ordinary number of pilgrims at the annual *Fair* amounts to 100,000, and at the *Kumbh-mela* to 300,000. The Hardwar meeting also possesses considerable mercantile importance, being one of the principal horse-fairs in Upper India. Commodities of all kinds, Indian and European, find a ready sale, and the trade in grain and food-stuffs forms a lucrative traffic. The Ganges canal draws its supply of water from a branch channel close to the town. Hardwar is a police station, with post and telegraph offices.

HARDY, ALEXANDRE (1600-1631), the most fertile of all dramatic authors, next to Lope de Vega and Calderon, merits a place in dramatic literature on that account alone. He is said to have written upwards of six hundred plays, of which forty-one were printed in his own edition of 1624-28, and may still be read. It cannot be charged upon modern writers that they are slow to see merit in early French authors, but it has been found impossible by any to admire the hasty works of a man who wrote a tragedy in eight days, and did not scruple to borrow situations from any quarter where he could find them. He at first followed a strolling company as its author, and ended by becoming the dramatist of the Théâtre du Marais. He knew how to make the most of his situations; he, evidently by constant practice, became a master of stage business and stage effects. He knew the kind of dialogue—nowise and rough—which would please his audience, his art, compared with that of Molière, his successor, is that of a carpenter compared with that of a sculptor. To the student of the drama Hardy will always be an interesting figure, appearing as he does between the degraded morality and the modern comedy, an imitator alike of Italian pastoral and Spanish tragedy. He had no sympathy with the classical pretensions of Jodelle, he gave little heed to art, he thought entirely of what would succeed for the moment. One piece alone of Hardy's has succeeded in arresting the attention of critics, the tragedy of *Marianne*. Hardy lived long enough to witness the first successes of Corneille.

HARDYNG, or HARDING, JOHN, an English rhyming chronicler of the 16th century, was born in 1378. Having been admitted as the age of twelve to the household of Henry Hotspur, son of the earl of Northumberland, he was afterwards present with his patron at the battles of Homildon (1402) and Cokolaw, and saw him fall in the fatal field of Shrewsbury (1403). He next entered the service of Sir Robert Umfraville, and held for some time the post of constable of the castle of Warkworth. In the beginning of the reign of King Henry V. he was commissioned to recover as many as possible of the deeds connected with the homage of the Scottish kings to the English crown, and we find him some time after presenting the results of his search to Henry at Bos de Vincennes. In recognition of his exertions he was promised the manor of Geflington in Northamptonshire (worth in the money of the time from £32 to £36), but the king dying before he obtained possession he was left, as he tells us, "without reward or lyfeloed any wise." Beyond a stray notice in the Lansdowne MS. of his chronicle, to the effect that Hardyng was in 1424 at Rome consulting and transcribing the chronicle of Trogon Pompeus, there is little trace of his proceedings till 1454, when he received a safe conduct from James of Scotland, that he might bring with him "the thynge which we spoke to you at Goldingham, of for which we bnde us by this letters to pay you a thousand marks of English nobles." A contract preserved in the Exchequer bears that in 1457 he delivered to the earl of Shrewsbury the letters in which David and Robert of Scotland recognized the English supremacy, and a number of less important documents of similar

tendency; and in the same year letters patent were issued granting him a pension of £20 per annum for life. The leisure of his old age appears to have been occupied with a revision of his chronicle, which he presented to Edward IV. It could not have been finished before 1465, but it only comes down to the flight of Henry VI. to Scotland. The purpose of the writer being "that English men might have understanding of all affairs touching their own countree Even to his dayes from all antiquite," he starts his narrative with Brutus the Trojan, and details the history of all the mythical kings. When he comes down to his own time a considerable part of the material is derived from his own experience. The Scottish portions are animated by strong national hostility: "unto the Scots he could never be friend."

The most important MSS. of Hardyng's Chronicle are the Lansdowne (20) and the Harleyan (601) in the British Museum, the Bodleian (*Archæol. Seld.*, B 10), and the Ashmolean. Richard Grafton printed two editions in January 1543, which differ in almost every page from each other. Grafton's abridgment was printed by Tottel in 1562, and again in 1564. Mr Ellis in 1812 edited the work from the Lansdowne MS., and prefixed a life of the author.

HARE, the common name of all the species, excepting the rabbit, of *Leporida*, a family of rodent mammals, distinguished from the rest of that order by the possession of four incisor teeth in the upper jaw, two in front, which are well developed and longitudinally grooved, and two exceedingly small ones behind. The molars are formed for the mastication of vegetable food, an uneven surface being produced by the presence of transverse enamel plates which are worn down more slowly than the intermediate dentine. The teeth are without permanent roots, and thus the constant waste at the surface is compensated for by continuous growth at the opposite extremity. Hares all possess long ears, and in most species the hind legs are much longer than those in front. They are without exception timid, defenceless animals, although during the breeding season two males have been known to fight together for possession

FIG. 1.—Common Hare.

of the female until one was killed; while all the species are protectively coloured. They form a single genus (*Lepus*), containing from thirty-five to forty species according as certain forms are regarded as independent species, or merely as geographical varieties. They occur in all the great zoological regions of the world, but are especially characteristic of the northern and temperate areas of both hemispheres.

The common hare (*Lepus timidus*, fig. 1) is a typical example of the family. The ears in this species are longer than the head, and its hind legs are so long in comparison with those in front, that it is only by descending a hill diagonally that it can avoid overbalancing itself. It is found in all parts of Europe except the north of Russia, the Scandinavian peninsula, and Ireland, and is especially abundant in those countries in which it enjoys the protection of game laws. Its fur is usually of a tawny grey colour above and white

beneath, with the upper surface of the short tail and the tips of the ears black. The colour of the fur, however, differs considerably in different latitudes and at different seasons of the year, showing, for example, a tendency to become white during winter in northern countries, while assuming a reddish-yellow hue in the more genial climate of southern Europe. On the strength mainly of such outward differences various species have been described, but these have been found to be so linked together by intermediate forms as to satisfy most naturalists that they are merely climatal varieties of one species. The hare is a night-feeding animal, remaining during the day on its "form," as the slight depression is called which it makes in the open field, usually among grass. This it leaves at nightfall to seek the fields of young wheat and other cereals whose tender herbage forms its favourite food. It is also fond of gnawing the bark of young trees, and thus often does great damage to plantations. In the morning it returns to its form, where it finds considerable protection in the close approach which the colour of its fur makes to that of its surroundings; should it thus fail, however, to elude observation it depends for safety on its extraordinary fleetness. On the first alarm of danger it is said to sit erect and to reconnoitre, when it either seeks concealment by clapping close to the ground, or takes to instant flight. In the latter case its great speed, and the cunning endeavours it makes to outwit its canine

FIG. 2.—Mountain Hare.

pursuers, form the chief attractions of coursing. The hare takes readily to the water, where it swims well; and Yarrell records an instance in which one was observed crossing an arm of the sea about a mile in width. Hares are remarkably prolific. They pair when scarcely a year old, and the female brings forth several broods in the year, each consisting of from two to five leverets (from the French *lever*), as the young are called. These have their sight at birth, and after being suckled for a month they are able to look after themselves. In Europe this species has never been known to breed in confinement. The hare was well known to the ancient Greeks and Romans.

In those parts where the common hare does not occur, its place is taken by the varying or mountain hare (*Lepus variabilis*, fig. 2). It is found throughout the entire northern portion of the great Palearctic region, from Ireland eastward to Japan, while it also occurs on the Pyrenees, the Alps, the highlands of Bavaria and the Caucasus, although altogether absent in the less elevated regions which connect these mountain ranges. Its presence in such isolated situations in company with many truly arctic plants is regarded as one of the many proofs of a former glacial epoch, during which boreal plants and animals were spread all over southern and central Europe. On the advent, however, of milder climatic conditions, this northern flora and fauna retired towards the Arctic Circle, leaving a few species, such

as the varying hare, behind on the various mountain ranges, where by ascending to a sufficient altitude the necessary local conditions could be obtained. The value of the hare as a species is in the south-eastern part of the mountain bare disjunct from the preceding species in its being shorter than its head, and in its fur becoming in most cases white in winter,—a change of colour which renders it almost invisible in the snow. Along the southern limit of its range, or in districts where the temperature is from any cause exceptionally mild, this change of colour either does not take place at all, as in Ireland, or is only partial, as in many parts of Scotland. In this respect it resembles the mink, which it further resembles in having a part of its fur always remaining black, in the hare, however, it is the tips of the ears, and not the point of the tail, which thus remain unaltered. In Scotland where it is known as the "blue hare," it occurs plentifully throughout the hilly regions north of the Forth, where it descends to the low grounds in winter, while in Ireland it is the only hare found. Owing to the mildness of the climate, however, in the "Green Isle," the colour of the fur undergoes little or no alteration in winter, and on this account it was until recently regarded by many as a distinct species (*Lepus hibernicus*). Throughout the Arctic regions of North America a closely allied species, the polar hare (*Lepus glacialis*), occurs. Naturalists have hitherto had considerable difficulty in distinguishing this from the preceding species, the chief difference being in the colour of the fur, which in the polar hare is white all the year round, with the exception of the tips of the ears. Considerable light has, however, been thrown on this point by the observations of the naturalists attached to the late Arctic Expedition under Sir George Nares, who found this species inhabiting the shores of Gunnell Land, and obtained evidence in foot-prints on the snow of its existence in latitude 83° 10', about 20 miles north of the nearest land. Unlike all other hares, and resembling in this respect the rabbit, the polar hare would seem to occupy a burrow—"a hole," says Captain Feilchen, "4 feet in length, scraped horizontally into a snow drift." "I have no doubt," he continues, "the same burrow is regularly occupied, as this one was discovered by the foot of the animal, and a quantity of hay was sticking to the sides." Another point of importance in establishing the specific distinctness of this species from the former lies in the difference in the number of young composing a brood in each of these species. The number of young found in gravid females by the naturalists already referred to varied from seven to eight, while in the varying hare of Europe the number does not exceed five. According to Captain Lyon, the polar hare is by no means as shy animal, as during his cruise in the Arctic seas hares were in the habit of coming out on the ice to his ships to feed on the sea leaves which were thrown overboard. This species has been found inhabiting the highest northern lands yet visited by man, where it also attains its normal weight of from 8 to 10 lb. subsisting on the storeweeds and other hardy plants which form the scanty vegetation of circumpolar valleys. The American varying hare (*Lepus americanus*) is one of the most widely distributed species of this family, extending, in one or other of its two geographical varieties, from the borders of the Arctic barren grounds southwards to New Mexico. It differs from the mountain hare of Europe in its smaller size and relatively smaller ears, but resembles it in the change of colour in the fur, especially of the northern varieties, during winter. It is exceedingly abundant on the banks of the Mackenzie River, where it is killed in great numbers by the Indians. A favourite device among the Indians for catching it, according to Darwin, is to walk spirally round and round it, when on its form, especially at midday when the shadow of the hunter is shortest. It has still more implacable enemies, however, in the wolves,

gluttons, and lynxes of those regions, of the last of which it is said to form the principal food. The fur of this species is imported into Great Britain, but it is of little value. In the swampy district of the south-eastern portion of the United States, the swamp hare (*Lepus aquaticus*) and the marsh hare (*Lepus palustris*) occur. These take readily to the water, and are said to dive for some distance, their legs being less thickly clothed with hair than are those of the less amphibious species. They feed chiefly on aquatic plants. Only one species of hare (*Lepus brasiliensis*) occurs in South America. It is found throughout Brazil, and on various parts of the Andes in Bolivia and Peru. Fossil remains of several species of *Lepus* have been found in the Post-Glacial deposits and the bone caves of Europe, while the remains of many extinct species have been lately discovered in the Miocene deposits of Dakota and Colorado.

HARE, JULIUS CHARLES (1795-1856), theological writer, was born at Valdarno, near Vicenza, in Italy, on the 13th of September 1795. He came to England with his parents in 1798, but in 1804-5 spent a winter with them at Weimar, where he met Goethe and Schiller, and received a bias to German literature which influenced his style and sentiments throughout his whole career. On the death of his mother in 1806, Julius was sent home to the Clontarf-house in London, where he remained till 1812, when he entered Trinity College, Cambridge. There he became a Fellow in 1818, and after some years spent abroad he began to visit London in the following year. In 1829 he was appointed assistant tutor at Trinity College, which position he retained for ten years. Turning his attention from law to divinity, Hare took priest's orders in 1826, and, on the death of his uncle in 1833, he succeeded to the rich family living of Thurston-cum- in Sussex, where he accumulated a library of some 12,000 volumes, especially rich in German literature. Before taking up residence on his parish he once more went abroad, and made in Rome the acquaintance of the Chivalier Bunsen, who afterwards dedicated to him part of his work, *Hypnotism and its Age*. In 1840 Hare was appointed a chaplain of Laws, and in the same year preached a course of sermons at Cambridge (*The Victory of Faith*), followed in 1846 by a second, *The Mission of the Comforter*. Neither series when published attained any great popularity. Archdeacon Hare married in 1844. In 1851 he was recalled to a pulpit in Chichester, and in 1853 he became one of the queen's chaplains. He died January 23, 1855.

Julius Hare belonged to what has been called the "Broad Church party," though some of his opinions approach very closely to those of the Evangelicalism of the day, while others again seem vague and undecided. He was one of the first of his countrymen to recognize and come under the influence of German thought and speculation, and, amidst an exaggerated alarm of German heresy, did much to moderate the intensity of the sound German critics. His writings, which are chiefly theological and controversial, are largely formed of charges to his clergy, and sermons on different topics. But, though valuable and full of thought, they lose some of their force by the cumbersome German structure of the sentences, and by certain orthographical peculiarities in which the author indulged. In 1827 *Questions at Truth by Two Brothers* appeared. There ensued Thirlwall's article in *Edinburgh Review*, in the translation of the 1st and 2d volumes of Niebuhr's *History of Rome* (1828 and 1832), and published a *Predication of Niebuhr's History* in 1839. He wrote many similar works, among which is a *Predication of Luther against his recent English followers*, 1854. In 1848 he edited the *Remains of John Sterling*, who had formerly been his curate. Carlyle's *Life of John Sterling* was written through dissemination with the "Life" published to Archdeacon Hare's book *Memoirs of a Great Life*, published in 1872, contains accounts of the Hare family.

Julius Hare's co-worker in this book was his brother Augustus William Hare (1792-1834), who, after a distinguished career at Oxford, was appointed rector of Alton Barnes, Wiltshire. He died prematurely in Rome in 1834. He was the author of *Sermons to a Country Congregation*, published in 1837.

HAIREBELL, or, as the name is often written, HAIRBELL, known also as the Blue-bell of Scotland, and Witches' Thimble, a well-known perennial wild flower, *Campanula rotundifolia*, L., a member of the natural order, *Campanulaceae*.

The hairbell has a very slender slightly creeping root-stock, and a wiry, erect stem. The radical leaves, to which the specific name refers, have long stalks, and are roundish or cordate, crenate or serrate, the lower stem leaves are ovate or lanceolate, and the upper ones linear, subsessile, acute and entire, rarely pubescent. The flowers are slightly drooping, arranged in a panicle, or in small specimens single, having the caly-tube glabrous, with subulate and erect segments, the corolla campanulate, with slightly recurved segments, and the capsule nodding, and opening by pores at the base of the caly-tube. There are two varieties — (a) *gemina*, with slender stem leaves, and (b) *montana*, in which the lower stem-leaves are elliptical-obovate. The plant is found on heaths and pastures throughout Great Britain and North America, and flowers in late summer and autumn. The hairbell has ever been a great favourite with poets, and on account of its delicate blue colour has been considered as an emblem of purity.

HAREM, or less frequently HARAM, the recognized European title for that portion of a polygamist's house which is devoted to the exclusive occupancy of his wives and their attendants, or, by a simple metonymy, for the female portion of his household. The word *harem* is Arabic for anything forbidden or not to be touched. It is generally applied in Moslem law to such things as games of chance, draughts, chess, witchcraft, and pot-smoking, which are inconsistent with the religious code, and under the form of haram it is well known even to Europeans as designating the sacred enclosure of the principal mosque at Cairo and at Jerusalem (*Haram esch-Scherif*). The word *seraglio*, which is not unfrequently employed as equivalent to harem, is an Italian modification (usually spelled *seraglio* from assimilation to *sera*, to shut in) of the Persian term *seray*, which simply means a palace or large building, as in the familiar compound *caravanserai*. Wherever polygamy is maintained in the midst of a developed social life, the harem appears to be an almost inevitable institution. We consequently find it at a more or less rigid type among the Jews, the Babylonians, the Siamese, the ancient Persians, the Persians, &c. But it is among the modern Mahometan peoples that it has attained its most perfect development, and the harems of the sultan of Turkey and the shah of Persia may be taken as the most elaborate and best known specimens of the type.

According to the Koran, the Mussulman is required to satisfy himself with four wives, but the sultan may possess as many as seven. Each of these has her own suite of apartments, her own garden and bath-room, and her own body of servants, male and female. They are not called by their names, but distinguished as *Kadin* (or Lady) Number One, *Kadin* Number Two, and so on. The title of sultana is bestowed only on the mother, the sister, or the daughter of a sultan, and consequently it is the *kadin* who first gives

Hairebell (*Campanula rotundifolia*)

birth to an heir to the empire who alone can have this distinction. She further obtains the title of *hasseky* or *kassiki*, but this is lost if the child dies. All the female slaves, or as they are called *odalisks* (a European corruption of the word *odalik*, from *oda* a chamber, and *lik* belonging to), are at the absolute disposal of the sultan, and if, in spite of the natural endeavours of the *kadins* to prevent such a contingency, one of them becomes the mother of his lord and master's first-born, she is advanced to the rank of sultana *hasseky*. It is contrary to etiquette for the sultan to select his own favourites among the *odalisks*, he is expected to accept the choice made for him by his mother, who bears the title of *valide*, and excurses great influence not only in the affairs of the harem but even in political matters. Every *odalisk* who has been promoted to the royal couch is henceforth considered sacred from all menial perturbation, and receives apartments and attendants of her own, but she has no further claim to the sultan's attention, and may have to console a life-long widowhood with the memory of the honour which was once bestowed on her. The ranks of the *odalisks* are even and anon recruited by slaves presented to the sultan by his female relatives or the state officials. The latter, for example, are accustomed to make acknowledgment of their allegiance in this way every year on the evening before the 15th of Ramadan. An old and devoted favourite of the sultan occupies the post of *haseky* *hasseky*, or lady-superintendent of the harem, a large body of eunuchs, both black and white, are employed as guards and gate keepers. The white eunuchs have charge of the outer gates of the seraglio, but they are not allowed to approach the women's apartments, and obtain no posts of distinction. Their chief, however, the *kaymak* *aghasey*, or master of the gates, has part control over the ecclesiastical possessions, and even the *vizier* cannot enter the royal apartments without his permission. The black eunuchs have the right of entering the gardens and chambers of the harem. Their chief, usually called the *kizlar* *aghasey*, or master of the maidens, though his true title is *dar ul-ma'at* *agha*, or chief of the abode of felicity, is an official of high import-ance. His appointment is for life. If he is deprived of his post he recovers his freedom, and if he recovers of his own accord he is generally sent to Egypt with a pension of 100 francs a day. His secretary keeps count of the revenues of the mosques built by the sultans. He is usually succeeded by the second eunuch, who bears the title of treasurer or *kaznahdar*, and has charge of the jewels, &c., of the women. The number of eunuchs is always a large one. The sultana *valide* and the sultana *hasseky* have each fifty at their service, and others are assigned to the *kadins* and the favourite *odalisks*.

Further details on the Sultan's harem will be found in an anonymous paper in the *Review* (London, 1851), in the *Calcutta* article by Hoffman in *Ernst* and Grubler's *Encyclopaedia*, and the *Seraglio del gran visir* (Venice, 1871) by Ottomano Doni, Venetian ambassador in 1608. An account of a visit to the harem of the Persian prince Melik Ismail Mirza was given by M. Flaudin in the *Revue des Deux Mondes* (1852), and at the time created great sensation in Paris. Sketches of harem interiors are common in our popular literature from Lady Mary Wortley Montagu's *Letters* and Lemercier's *Tour de Persie* (1793) down to M. St. Hippolyte's *Two* *ish* *Extraneous* and *Cassian* *Extraneous* (London, 1871). The Count de Beauvoir gives a picture of the interiors of the sultan of Persia and the Siamese mandarin in his *Panorama of the World* (London, 1870). Much interesting information on harem life is given as supplied by Dr Hantzsche (who as a physician was sometimes admissible to the harem) in *Zeitschrift für allgemeine Ethnologie* (Berlin, 1864).

HARFLEUR, the Harfleur of our older historians, a maritime town of France in the Department of Seine Inférieure and arrondissement of Harfleur, about 6 miles E. of Havre on the railway between that city and Rouen. It lies in the fertile valley of the *Lezard*, at the foot of wooded hills not far from the northern bank of the

portant science amongst a people whose every rule of religion and of life depended upon the accurate interpretation of some word in passage of the Koran, or some saying of the prophet. The rival school of Kufa was the only one that approached it in fame or glory, and in all the numerous disputes that took place between the two academies Busrarhi is generally allowed to have had the advantage. His name Hariri signifies silk-merchant, and was probably derived from his father's occupation, as, in spite of the assertion of his biographers to that effect, he appears not to have ever engaged in trade, but to have devoted himself exclusively to literary pursuits. His great object was to investigate the niceties of the Arabic language, and he composed several treatises on the subject, amongst which the best known are *Molhat el 'Arab* (Beauties of Desinential Syntax) and *Durrat el Ghawada* (The Diver's Pearl), in which he criticises certain common faults of language in vogue amongst the educated. Portions of both these works have been published by Do Sacy in his *Choix orientales*, and the *Durrat el Ghawada* has been edited by H. Thibbecke (Leipzig, 1871). But his great work is the *Makamat*, or "Assemblies," in which a series of anecdotes of a very slight character in the career of an imaginary learned vagabond afford the opportunity for the display of vast philological and literary learning. The plan was not original, having been already invented and used by Badî' az Zamân al Hamadânî, who died about 1008. The composition of Hariri's own *Makamat* is attributed to the following circumstance: Being one day in the mosque of the Basm Hassan in the quarter of Busrarhi in which he resided, he noticed an old man enter, shabby and worn with travel, who in answer to his questions of the persons present gave his name as Abu Zeid, and said that he came from Serâj, a city near Edessa, which had recently been devastated by the crusaders. The old man related the incidents of the destruction of his native city and his own domestic losses and exile in so eloquent a strain as to excite general admiration and compassion. On reaching his home Hariri wrote out the incident in the form of a makamat or assembly, in the style of El Hamadânî's work, and it now forms the 48th of his book. When subsequently elaborating the idea he modelled the successive chapters on the same theme, a simple minded Arab gentleman, El Haith ibn al Hammâm, on his travels constantly meets with a vagabond old impostor, Abu Zeid, who, under different characters and disguises, always succeeds in eliciting the sympathy and alms of his audience and the approbation of El Haith himself. Abu Zeid is always poor, ill dressed, and crafty, but eloquent in the extreme, and his fraudulently obtained gains are always spent in some forbidden enjoyment, yet there is ever a good side to his character, and he is not without an exhibition of true feeling, especially when he alludes to the circumstances of his expulsion from his home, and the loss of his daughter, who had been made captive by the marauding Franks. The improvised speeches of Abu Zeid are masterpieces of Arabic learning, every sentence being made to introduce some allusion to Arab history, poetry, or tradition, or the discussion and elucidation of some difficult point of rhetoric or grammar. It is this that gives the value to the book and makes it with its commentary a complete encyclopedia of classical Arabic literature and philology. It is written in rhymed and rhythmical prose, such as is used in the Koran itself, interspersed with verses of poetry of which the merit is more often in the language than the thought.

The *Makamat* have been edited by Silvestre de Sacy, with a select Arabic commentary (Paris, 1822), and a new edition of this edition with numerous French notes, was issued by MM. Reinaud and Darandouze (Paris, 1858). An English translation of some select "Assemblies" was made by Theodore Freuden for the Oriental Translation Fund (London, 1860), and an admirable translation of

the first twenty six assemblies by T. Chomery (London, 1867), containing an introduction and notes, and a resume of all the literature of the subject. Of the numerous editions of the *Makamat* of Hariri, the best known are the *Makamat al-Hariri*, a Hebrew work by Yehuda ben Shelomoh al-Khazari, edited by T. Chomery (London, 1872), and the *Magna 'al Bahian* (Confession of the Two Sides), by Nuri al-Yazûrî (Beirut, 1853), an excellent work in Arabic, displaying an immense acquaintance with the ancient literature of the language. (S. H. P.)

HARLEQUIN. See PANTOMIME.

HARLEY. See OXFORD, EARL OF.

HARLINGEN, or **HAARLINGEN**, in *Frison Harns*, an important trading town and seaport in the province of Friesland in the Netherlands, is situated 17 miles W of Leeuwarden with which it has been connected by rail since 1863. Besides its dilapidated fortifications, and the town-house, which was erected between 1730 and 1733 and is adorned with a statue of the historian Simon Stijl, the only noteworthy buildings are the Great or New church, the West church, which was formerly part of the castle, the Roman Catholic church, and the Jewish synagogue. The school of navigation and school of design may also be mentioned. Harlingen is the seat of the Frisian Navigation Company, and it has regular steam communication, not only with Amsterdam and Nieuwe Diep, but also with London and Hull. Besides an inner harbour protected from the high tides by powerful sluices, it has an outer harbour of modern construction for the accommodation of large vessels. One of the chief departments of its trade is the export to England of Frisian produce—corn, cattle, butter, cheese, and flax. Wharves, saw-mills, anchor forges, rope yards, and a canvas factory represent the auxiliary industries of the place. In the middle of the last century, Harlingen had 7000 inhabitants, which increased in the course of the next hundred years to about 8000. In 1860, before the new harbour works, they numbered 9800, and in 1878 they were 10,800.

Originally Harlingen was only a part of the village of Almmunn, and lay at some distance inland, but the Zuyder Zee, which had already in 1184 destroyed an intervening town, made another road in 1506 and attained its present limits. The Spanish lieutenant Campa Robles du Bolly, whose monument, the "Man of Stone," now stands on the sea dyke, took care to protect the site of the town by further embankments. In 1670 it was surrounded by walls and fosses, a new castle had been built in 1662. During the civil wars of 1787 Huisman was blockaded by the patriots of Franeker. In November 1776 and February 1825 it suffered from severe inundations.

HARMODIUS, a beautiful Athenian of the tribe Gephyria, was the intimate friend of Aristogiton, a citizen of the middle rank. Hipparchus, younger brother of the tyrant Hippasus, was also a lover of Harmodius. He tried to attract Harmodius to himself, and failing in the attempt, revenged himself by putting a public affront on his sister at a solemn festival. Thereupon the two friends conspired with a few others to murder both the tyrants during the armed procession at the Panathenæan festival (514 B.C.). But in a sudden alarm they prematurely attacked and slew Hipparchus alone. Harmodius was executed on the spot by the guards, and Aristogiton was soon captured and tortured to death. When Hippasus was expelled (510 B.C.), Harmodius and Aristogiton became the most popular of Athenian heroes, their statues were set up in the agora, their descendants were exempted from public burdens, and their names were celebrated in popular songs and scolia as the deliverers of fair Athens. Thucydides (vi. 54) alludes to the falseness of the popular belief about them, and gives the story in detail.

HARMONIA, wife of Cadmus. The Theban legends (see CADMUS) have been so modified and systematized by poets and logographers that we must look to Samothrace with its old religious rites for an explanation of the myth. There Harmonia is said to have been the daughter of Zeus and Electra, while her brother Jason was the founder of

the mystic rites which were celebrated annually on the island. When Cadmus came to Semothrace, and was initiated, he received Harmonia as his wife. The gods honoured the wedding with their presence, Athena presented the bride with a peplos and necklace, Electra gave the mystic rites of the mother of the gods. According to the scholiast on Euripides (*Phoen.*, 1) Cadmus with the aid of Athena carried off Harmonia, and in the mysteries the lost Harmonia is regularly sought for. We have here an exact parallel to the Eleusinian legends. Electra and Harmonia are more varieties of Demeter and Kore. Cadmus like Pluto carries off the bright daughter of the goddess to the world below to spend there the dreary winter. Hence in the Theban tale Cadmus and Harmonia leave Thebes to go away among the Thracians, the snake people, as themselves changed into serpents, and are finally translated to the Elysian fields. We then understand, too, why (according to Pansanias, ix. 16, 3) Cadmus dwelt at Thebes in the temple of Demeter Thesmophoros. The necklace, wrought by Hephaestus, which Harmonia received as a marriage gift, may be compared with the orestes of Aphrodite, for it is impossible to draw a fast line between Harmonia or Kore and Aphrodite. Then it is seen to be the mythic representative of some phenomenon like the light of dawn, the rainbow. Like the works of the German dwarfs, this necklace carried with it luck, and the legends give it a history of woe. With it Polynices bribed Eurydice to betray her husband Amphidamas. It brought death at last to her son Alcibiades. Dedicated in the temple of Athene Pronaia at Delphi, it was given by the tyrant Phayllus (363 B.C.) to his mistress, her son going mad yet fled to the house, and she perished in the conflagration.

HARMONICA is the technical name for the "musical glasses" with the learned conversation about which the people have from time to time the simple-minded view of Walsford. An instrument for producing musical sounds by means of drinking glasses touched with the moistened fingers was, however, known 100 years before Goldsmith's novel. What its exact nature may have been cannot now be ascertained, but its mode of playing must have been far from perfect, for as late as the middle of the 18th century the musical glasses played by Mr Packard were placed on a table and their pitch was fixed by the quantity of water they contained, naturally a very uncertain mode of determination. It was to this instrument that the great Benjamin Franklin applied his improvements described in his letter to Father Beccaria of Turin. Instead of filling the glasses he made them rotate round a spindle set in motion by the player's foot by means of a treadle. The edge of the glasses by the same means passed through a basin of water, the pitch henceforth being determined by the size of the glasses alone. The player touched the brims of the revolving glasses with his finger, his task being further facilitated by the scale of colour which Franklin adopted in accordance with the musical gamut. Thus G was red, D orange, E yellow, F green, G blue, A indigo, and B violet. The black keys of the piano were represented by white glasses. The instrument thus improved became very fashionable in England, and a Miss Davis, a relation of Franklin's, became a celebrated harmonica player, who performed at numerous concerts with great applause. It is interesting to know that the great composer Gluck was a virtuoso on the musical glasses in their earlier form, which he played, according to a contemporary advertisement, at the Haymarket Theatre, April 23, 1746. He even seems to have claimed the instrument as his own invention, and promises to "perform upon it whatever may be done on a violin or harpsichord." Nowadays the idea of a composer of repute—for such Gluck was at the time—playing on the

musical glasses would appear grotesque. But the notions of æsthetic dignity were different in the 18th century. Many attempts have been made to increase the power and flexibility of the harmonica, and also to avoid the nervous instability said to be caused by the friction of the vibrating glasses. Thus harmonicas played with the bow or by means of a keyboard, like that of the pianoforte, have been invented. But none of these has met with permanent success, and in all essential points the modern harmonica is such as Franklin left it.

HARMONIC ANALYSIS is the name given by Sir William Thomson and Professor Tait in their treatise on *Natural Philosophy* to a general method of investigating physical questions, the onliest applications of which seem to have been suggested by the study of the vibrations of stings and the analysis of these vibrations into their fundamental tone and its harmonics or overtones.

The motion of a uniform stretched string fixed at both ends is a periodic motion, that is to say, after a certain interval of time, called the fundamental period of the motion, the form of the string and the velocity of every part of it are the same as before, provided that the energy of the motion has not been sensibly dissipated during the period.

There are two distinct methods of investigating the motion of a uniform stretched string. One of these may be called the wave method, and the other the harmonic method. The wave method is founded on the theorem that in a stretched string of infinite length a wave of any form may be propagated in either direction with a certain velocity, V , which we may define as the "velocity of propagation." If a wave of any form travelling in the positive direction meets another travelling in the opposite direction, the form of which is such that the lines joining corresponding points of the two waves are all bisected in a fixed point in the line of the string, then the point of the string corresponding to this point will remain fixed, while the two waves pass it in opposite directions. If we now suppose that the form of the waves travelling in the positive direction is periodic, that is to say, that after the wave has travelled forward a distance λ , the position of every particle of the string is the same as it was at first, then λ is called the wave-length, and the time of travelling a wave-length is called the period or time, which we shall denote by T , so that

$$\lambda = VT$$

If we now suppose a set of waves similar to these, but reversed in position, to be travelling in the opposite direction, then there will be certain points, distant λ from each other, at which there will be no motion of the string, it will therefore make no difference to the motion of the string if we suppose the string fastened to fixed supports at any two of these points, and we may then suppose the parts of the string beyond these points to be removed, as it cannot affect the motion of the part which is between them. We have thus arrived at the case of a uniform string stretched between two fixed supports, and we conclude that the motion of the string may be completely represented as the resultant of two sets of periodic waves travelling in opposite directions, then wave-lengths being either twice the distance between the fixed points or a submultiple of this wave-length, and the form of these waves, subject to this condition, being perfectly arbitrary.

To make the problem a definite one, we may suppose the initial displacement and velocity of every particle of the string given in terms of its distance from one end of the string, and from these data it is easy to calculate the form which is common to all the travelling waves. The form of the string at any subsequent time may then be deduced by calculating the positions of the two sets of waves at that time, and compounding their displacements.

Thus in the wave method the actual motion of the string is considered as the resultant of two wave motions, neither of which is of itself, and without the other, consistent with the condition that the ends of the string are fixed. Each of the wave motions is periodic with a wave-length equal to twice the distance between the fixed points, and the one set of waves is the reverse of the other in respect of displacement and velocity and direction of propagation, but, subject to these conditions, the form of the wave is perfectly arbitrary. The motion of a particle of the string, being determined by the two waves which pass over it in opposite directions, is of an equally arbitrary type.

In the harmonic method, on the other hand, the motion of the string is regarded as compounded of a series of vibratory motions, which may be infinite in number, but each of which is perfectly definite in type, and is in fact a particular solution of the problem of the motion of a string with its ends fixed.

A simple harmonic motion is thus defined by Thomson and Tait (§ 53) — When a point Q moves uniformly in a circle, the perpendicular QP , drawn from its position at any instant to a fixed diameter AA' of the circle, intersects the diameter in a point P whose position changes by a simple harmonic motion.

The amplitude of a simple harmonic motion is the range on one side or the other of the middle point of the course. The period of a simple harmonic motion is the time which elapses from any instant until the moving-point again moves in the same direction through the same position.

The phase of a simple harmonic motion at any instant is the fraction of the whole period which has elapsed since the moving point last passed through its middle position in the positive direction.

In the case of the stretched string, it is only in certain particular cases that the motion of a particle of the string is a simple harmonic motion. In these particular cases the form of the string at any instant is that of a curve of sines having the line joining the fixed points for its axis, and passing through these two points, and therefore having for its wave-length either twice the length of the string or some submultiple of this wave-length. The amplitude of the curve of sines is a simple harmonic function of the time, the period being either the fundamental period or some submultiple of the fundamental period. Every one of these modes of vibration is dynamically possible by itself, and any number of them may coexist independently of each other.

By a proper adjustment of the initial amplitude and phase of each of these modes of vibration, so that their resultant shall represent the initial state of the string, we obtain a new representation of the whole motion of the string, in which it is seen to be the resultant of a series of simple harmonic vibrations whose periods are the fundamental period and its submultiples. The determination of the amplitudes and phases of the several simple harmonic vibrations so as to satisfy the initial conditions is an example of harmonic analysis.

We have thus two methods of solving the partial differential equation of the motion of a string. The first, which we have called the wave method, exhibits the solution in the form containing an arbitrary function, the nature of which must be determined from the initial conditions. The second, or harmonic method, leads to a series of terms involving sines and cosines, the coefficients of which have to be determined. The harmonic method may be defined in a more general manner as a method by which the solution of any actual problem may be obtained as the sum or resultant of a number of terms, each of which is a solution of a particular case of the problem. The nature of these particular cases is defined by the condition that any one of them must be conjugate to any other.

The mathematical test of conjugacy is that the energy of the system arising from two of the harmonics existing together is equal to the sum of the energy arising from the two harmonics taken separately. In other words, no part of the energy depends on the product of the amplitudes of two different harmonics. When two modes of motion of the same system are conjugate to each other, the existence of one of them does not affect the other.

The simplest case of harmonic analysis, that of which the treatment of the vibrating string is an example, is completely investigated in what is known as Fourier's theorem.

Fourier's theorem asserts that any periodic function of a single variable period 2π , which does not become infinite at any phase, can be expanded in the form of a series consisting of a constant term, together with a double series of terms, one set involving cosines and the other sines of multiples of the phase.

Thus if $\phi(\xi)$ is a periodic function of the variable ξ having a period 2π , then it may be expanded as follows:

$$\phi(\xi) = A_0 + \sum_1^\infty A_n \cos \frac{2n\pi\xi}{2\pi} + \sum_1^\infty B_n \sin \frac{2n\pi\xi}{2\pi} \quad (1)$$

The part of the theorem which is most frequently required, and which also is the easiest to investigate, is the determination of the values of the coefficients A_0, A_n, B_n . These are

$$A_0 = \frac{1}{2\pi} \int_0^{2\pi} \phi(\xi) d\xi, \\ A_n = \frac{1}{2\pi} \int_0^{2\pi} \phi(\xi) \cos \frac{2n\pi\xi}{2\pi} d\xi, \\ B_n = \frac{1}{2\pi} \int_0^{2\pi} \phi(\xi) \sin \frac{2n\pi\xi}{2\pi} d\xi$$

This part of the theorem may be verified at once by multiplying both sides of (1) by $d\xi$, by $\cos \frac{2n\pi\xi}{2\pi} d\xi$, or by $\sin \frac{2n\pi\xi}{2\pi} d\xi$, and in each case integrating from 0 to 2π .

The series is evidently single-valued for any given value of ξ . It cannot therefore represent a function of ξ which has more than one value, or which becomes infinitely large for any value of ξ . It is convergent, approaching to the true value of $\phi(\xi)$ for all values of ξ such that if ξ varies infinitesimally the function also varies infinitesimally.

Sir W. Thomson, availing himself of the disk, globe, and cylinder integrating machine invented by his brother, Professor James Thomson, has constructed a machine by which eight of the integrals required for the expression of Fourier's series can be obtained simultaneously from the recorded trace of any periodically variable quantity, such as the height of the tide, the temperature or pressure of the atmosphere, or the intensity of the different components of terrestrial magnetism. If it were not on account of the waste of time, instead of having a curve drawn by the action of the tide, and the curve afterwards acted on by the machine, the time axis of the machine itself might be driven by a clock, and the tide itself might work the second variable of the machine, but his would involve the constant presence of an expensive machine at every tidal station.

It would not be devoid of interest, had we opportunity for it, to trace the analogy between these mathematical and mechanical methods of harmonic analysis and the dynamical processes which go on when a compound ray of light is analysed into its simple vibrations by a prism, when a particular overtone is selected from a complex tone by a resonator, or when the enormously complicated sound-wave of an orchestra, or even the discordant clamours of a crowd, are interpreted into intelligible music or language by the attentive listener, armed with the help of three thousand strings, the resonance of which, as it hangs in the gateway of his ear, discriminates the multitudinous components of the waves of the aural ocean. (p. c. x.)

HARMONIUM. Perhaps no musical instrument ever became in a few years so widely known and used as the harmonium. The reasons for this may at once be found in the facilities it offers for playing easy music, and when simply constructed, its comparatively low price, which renders the purchase of a tolerable harmonium possible when the cheapest pianoforte fairly playable would be unattainable, and the real organ, although of chamber size, quite out of the question. Besides being a convenient makeshift for an organ, the harmonium can also be used in domestic concerted music, to play all or any of the wind band parts of the orchestra, it may even be employed as a substitute for the violin, and in such various uses it is just all question one of the hands of the operator.

It is into the tone of the harmonium we are not in itself beautiful, the prominence in sounds from reeds of certain overtones is unaccountable with pleasure to the ear unless by convention of habit, and the necessity of tuning according to equal temperament all major thirds too sharp leads through this harmonic peculiarity in the chords to an abnormally disagreeable quality, from which those whose nerves are very sensitive or weak are not unfrequently painfully affected. The American organ, a kind of harmonium of late years much in vogue, owes its popularity to its being less pronounced and reedy in timbre (its softer tone being nearer to that we are familiar with in the church organ), and its being easier to play for simple domestic use. Yet the real harmonium has more independent character as an instrument, and is capable of higher treatment in performance than the American organ.

Both are known as "free reed" instruments, the musical tones being produced by tongues of brass, technically "vibrators," set in oblong frames, the sides of those they do not quite touch, but pass, when in movement, freely downwind, — the "beating reeds" used in church organs covering the entire office. A reed or vibrator, set in periodic motion by impact of a current of air, produces a corresponding succession of air puffs, the rapidity of which determines the pitch of the musical note. There is an essential difference between the harmonium and the American organ in the direction of this current, in the former the wind apparatus forces the current upwards, and in the latter sucks it downwards, whence it becomes desirable to separate in description these varieties of free-reed instruments.

The *Harmonium* line a keyboard of five octaves compose when complete, from C to C, and a simple action controlling the valves, or "stops," by means of which wind is regulated by bellows worked by the feet of the performer upon footboards or pedals. The air is thus forced up the wind tubes into an air-chamber called the wind chest, the pressure of it being equalized by a reservoir, which receives the excess of wind through an opening and permits, moreover, when also a certain pressure, by a discharge valve or pallet. The aperture admitting air to the reservoir may be closed by a diaphragm named "expression." The character of the instrument is then entirely changed from a mechanical response to the player's touch to an expressive one, yielding what motion may be communicated from the player by increase or diminution of sound through the greater or less pressure of wind the reeds may be submitted to. The diaphragm being the wind flange of the keyboard, as the dividing bell stops into bass and treble. A stop being drawn and a key pressed down wind is admitted by a corresponding valve to a reed or vibrator. Above each reed in the so-called sound board or grill in a chamber, a small air chamber or cavity, the shape and capacity of which have greatly to do with the colour of tone of the note it reinforces. The air in this resonator is highly compressed at an even or varying pressure as the expression-stop may not be or may be drawn. The wind finally escapes by a small pipe being opened by pressing down the corresponding key. In *Musical* and other good harmoniums, the reed compartments that form the scheme of the instrument are eight in number, four bass and four treble, of three different pitches of octave and double octave the

tance. The front bass and treble rows are the "disposition" of the public known is 8 feet, and the horizontal (double octave) row, 16 feet. These may be regarded as the foundation stops, and are to themselves the front organ. The back organ has solo and combination stops, the principal of it has (active higher than in disposition), and basson (first) and cello (in block) 8 feet. This may be indicated by a stop called full organ. At *Musical*, the French make, whose pre-eminence is universally acknowledged, has added other registers for such additional effects as those of "harps, cellos," two bass voices of 2 feet pitch, the one named a bent bass voice, the other a bent too flat, to produce a wailing tremulous tone that it has a certain charm. "Must the organ" "voice cello," 16 feet, and "bassoon" while stop 32 feet, or two or three down from the not a note of the key. The "back organ" is usually indicated by a small bell, containing laminae or shuttles similar to a Venetian blind, and divided into four parts corresponding with the four and the division of the registers. The notes are produced by means of a valve which is put under the pressure. Turning the reeds is effected by squeezing them at the point to sharpen them, or men the shoulder of back to flatten them in pitch. An expressive effect the pitch of the reeds, notice this only in the larger reeds, may sometimes long return than tuning, a decided advantage over the organ and the pianoforte. Mechanical contrivances in the harmonium, of frequent or occasional employment, besides those already indicated, are, as the "expression," a small pneumatic action of hammer and escapement which, acting upon the sides of the disposition rows at the moment in is admitted to them gives prompt response to the depression of the key, or quick speech, the "double express" one, a pneumatic linkage in the wind chest which causes the reeds to exactly imitating by gradation and pressure of the wind, and the "double touch," by which the back organ requires speak sooner in those of the front than is elicited upon by deeper pressure of the key, these three, the "double touch" is a certain part of certain parts by an expert performer. "Blowing out" permits selected notes to be sustained after the fingers have quitted their keys. Besides a "melody attachment" to give mechanical aid to an air or to the pitch shifting off an action register, it notes selected. This motion is been adapted by an organ to a "pitch substitute" to strengthen the lower harmonies. The "trill" affects the wind in the vicinity of the reed, so that it is set in motion, it causes the vibration in a rapidly receding to produce, and the "combiner" diminishes the supply of wind by controlling it, and is known to the reed.

The *American Organ*, as already said, is a wind instrument. A vacuum is usually created in the wind chamber by the exhausting power of the footboards, and a current of air thus driven downwards passes through any reeds that are left open, setting them in vibration. The instrument has therefore a current of air of force below. Valves in the board above the air chamber give communication to reeds, in some more delicate than those of the harmonium and more of key bent, while the more in which they are fixed are the differently shaped, being hollowed inward in upon fashion. The channels, the openings above the reeds, are not used in any or simple as in the harmonium, they exactly correspond with the reeds, and no considerable space in the tube-board. The small "bells" are in front of the openings of these tabs, small tabs open or close by the action of the keys upon which they are called knee pedals. The tone of the American organ is softer than that of the harmonium. This is caused by the action of the reeds of a vacuum, as, for instance, in Clough's *Wright's* latest instruments (of Detroit, Michigan, U.S.), which they call paper or qualifying tabs. The blowing being less exact, induces the use of long lasting. The "expression" stop has little effect in the American organ, and is generally omitted, the "in tone" swell" in the instruments of Mason and Hamlin of Boston, U.S., is the first comes into the American instrument. It is a well suited, or is kept in constant movement, proportioned to the force of the air-current. Another very clever improvement introduced by these makers, who are the originators of the instrument itself, is the "voicing handle," a valve with a handle, made to revolve rapidly by wind pressure, its rotation, disturbing the air as the reeds, causes interference of vibration that produces a tremulous effect, not unlike the beating heard from congested valves, whence the name. This valuable stop has found general adoption. The arrangement of reed compartments in American organs does not essentially differ from that of harmoniums, but there are often two keyboards, and thus the solo and combination stops are on the upper manual. The difference in table registers is known as "melody" — different makes occasionally vary the use of fancy names for other stops. The "subbass," however, an octave of 16 feet pitch and always present in the American instrument, is a great advantage in its effects on the manual, the compass of American organs being usually down to 7 (FF, 6 octaves). In large instruments there are sometimes foot pedals as in an organ, with compasses of 8 and 16 feet, and a few notes of the octave down to 16 feet. Blowing for pedal instruments has to be done by hand a

level being attached to that purpose. The "celerate" stop is managed as in the harmonium, by rows of reeds tuned not quite in unison, or by a shade valve that alters the air current and flattens one row of reeds thereby.

Harmoniums and American organs are the results of many experiments to play upon free reeds by a keyboard, imitated by the "orgue expressif" of Giené, a Frenchman. During nearly the first half of this century various tentative efforts in France and Germany, and subsequently in England, came to nothing more valuable than the Viennese "physharmonica" of Hackel, the Parisian "melophone," and our own "seraphine." The inventor of the harmonium was indubitably Alexandre Debain, who took out a patent for it in Paris in 1840. He produced varied timbre registers by modifying reed channels, and brought these registers on to one keyboard. Unfortunately he patented too much, for he secured even the name harmonium, obliging contemporary and future experimenters to shelve their improvements under other names, and the venerable name of organ becoming imposed into connection with an inferior instrument, we have now to distinguish between reed and pipe organs. The compromise of reed organ for the harmonium class of instruments must therefore be accepted. Debain's harmonium was at first quite mechanical, it gained expression by the expression stop already described. The Alexandres, well known French makers, by the ingenuity of one of their workmen, Martin, added the percussion and the prolongement. The melody attachment was the invention of an English engineer, the introduction of the double touch, now used in the harmoniums of Mustel, Bauer, and others—also in American organs—is due to Mr. Tamplin, an English professor. Reference has already been made to the improvements of M. Mustel, a maker imbued with true artistic devotion.

The principle of the American organ originated with the Alexandres, whose earliest experiments are said to have been made with the view of constructing an instrument to exhaust air. The realization of the idea proving to be more in consonance with the genius of the American people, to whom what we may call the devotional tone of the instrument appealed, the introduction of it by Messrs. Mason and Hamlin in 1861 was followed by remarkable success. They made it generally known in Europe by exhibiting it at Paris in 1867, and from that time instruments have been exported in large numbers by different makers. Harmoniums are not entirely, although chiefly, of French make. Mr. Bauer, one of the best English makers, learned the trade in Paris, and employs chiefly French workmen. As keyed instruments, reed organs of either principle cannot be expected to compete musically with the older organ and pianoforte, yet the harmonium, studied for itself with something like the devotion that is given to the other keyed instruments, might be made more important than it is at present. Excepting from a few isolated students who may be told upon the fingers, it has received no true cultivation. Whether it will ever get this is a question that remains to be answered. Commercially the harmonium and American organ have taken a much more important place, although of course one not equal to that of the pianoforte. For some years the Alexandres were sending annually 7000 harmoniums to England. This afterwards, from various causes, diminished, the number, however, of their instruments made up to 1879 has reached 110,000. A general estimate of harmoniums made annually in France, Germany, and England is not forthcoming, but the yearly production of American organs in the United States has been stated at the large total of 40,000.

HARMONY See ACOUSTICS AND MUSIC

(A. J. H.)

HARÖ, said to be the ancient *Cæterum Biliann*, a town of Spain, is situated in the province of Logroño, and the bishopric of Calahorra, 12 miles S.E. of Miranda, and 58 miles N. of Madrid. It occupies a beautiful site near the Ebro, in a fertile plain, bounded by a range of mountains. The town contains a fine parish church, a theatre built in 1841, a hospital, and other public buildings. Various unimportant manufactures are carried on by the inhabitants, but the chief source of wealth is the red wine produced in great abundance from the vines of the surrounding plain. There are some copper mines in the neighbourhood. HARÖ was the birthplace of Diego de Leyva, the celebrated painter, about 1580. The population was estimated for 1879 at 6391.

HAROLD I., surnamed Fairhaired (Hárald Hinnfógr), the founder of the old royal dynasty of Norway, succeeded his father, Halfdan the Black, as jarl about the year 863. His ambition to become king is said to have been awakened by the refusal of Gyda, daughter of Eric of Hladaland, to marry him until he had made himself ruler of all Norway, as Gorm had of Denmark, and Eric of Sweden, and he vowed that he would never clip one comb his hair until he had fully achieved his task. After he had subjugated all the jarls, he gave to Gyda and made her one of his wives, and had his hair cut at a feast in Moss by Jarl Hognvald, who then gave him the name of *Hinnfógr*. During the wars of Harold with the jarls many of the Norsemen left their country and settled in Iceland, the Faeroe Islands, the Orkney and Shetland Islands, and even in the Highlands of Scotland, from whence they returned and committed many sea robberies in Norway. Harold therefore fitted out a great expedition, conquered and slew the vikings, and made himself ruler over all these Norse settlements. During his absence on another expedition against Jarl Einar of Orkney his sons made war on one another, and also committed many acts of violence against his jarls. Accordingly on his return, finding it difficult to keep them in check, Harold resolved to give them separate provinces to govern, and about the year 893 called together a great "thing," at which he conferred on each the title of king, with a seat higher than that of the jarls, he himself retaining the sovereignty of the whole country. He also made Eric Bloodaxe his heir, and took him to live with him, and about his eightieth year, when he found himself no longer able to discharge his kingly duties, he transferred the whole government to Eric and gave him the royal seat. Harold died three years afterwards about the year 933.

HAROLD II. surnamed Giesykin (Hárald Hinnfógr), son of Eric Bloodaxe, succeeded Haro the Good in the government of Norway about the year 960, having banished his other brothers to be satisfied with reigning as under kings in the other provinces. It would appear that Harold himself was disposed to govern peacefully and well, but his brothers now resolved to take vengeance on the friends of the late King Haro, and murdered among others Jarl Sigurd. They, however, failed of their purpose on Ilaco, his son, who after for some time resisting their attacks fled to Denmark, where he obtained the assistance of King Harold Bluetooth, with whose help he defeated and slew Harold Giesykin, upon which, under Harold Bluetooth, he became ruler of Norway with the title of jarl, according to some in the year 965, to others in 969, and to others in 975.

HAROLD III., surnamed Stein in Council (Hárald Hærrádræ or Hærrádræ), son of Jarl Sigurd, half-brother of King Olaf the Holy, and decended by his father from Harold I., was one of the most distinguished warriors among the old Norse kings. About his fifteenth year he made his escape wounded from the battle of Stiklestad (1030), where his half-brother Olaf was killed; and after staying till he was cured of his wounds with a "bonde" in a

forest, he made his way to Sweden, whence after the winter was over he went to Russia, where he was kindly received by King Yaroslav of Novgorod. He remained in Russia for several years, but, being refused the hand of a Russian princess, he betook himself with several companions to Constantinople, and became chief commander of the famous Byzantine light-guards known as Varangians, and consisting almost wholly of Norsemen. At the head of these warriors he gained many victories over the Saracens in Sicily and Italy. It is even said that in a crusade against the infidels he penetrated as far as Jerusalem, but most probably if he entered that city it was in the peaceful character of a pilgrim.

Returning after his exploits to Constantinople, he was refused the hand of a niece of the empress Zoe, because, according to the legend, the empress herself was enamoured of him, and offended at the refusal he one night made his escape with two galleys, carrying with him all his treasures, and also it is said the princess whose hand had been denied him, whom, however, he put on shore after he had passed the Doplous, with a message to the empress that, if he had so willed, her power would have been vain against his strategy and skill. He now set sail for Russia, where he was warmly welcomed by King Yaroslav, and as he was now a man of great fame and wealth Yaroslav gave him in marriage his daughter Ellsolf or Elizabeth, whose hand he had formerly asked in vain. Soon after his marriage he resolved to return home, and if possible to win the crown of Norway from his nephew Magnus the Good.

With that purpose he about the year 1045 came to an agreement with his relative Sverdr of Denmark, who had been driven by Magnus into exile in Sweden, but Magnus, having obtained news of the intended joint expedition against him, entered into communication with Harold, and agreed to share with him the government of Norway, each ruling over a separate division. They now turned their united forces against Sverdr, drove him from Denmark, and completely stripped him of his power, but when he had resolved humbly in despair to give up the contest, Magnus about the year 1047 took suddenly ill and died, bequeathing on his death-bed the whole of Norway to Harold and Denmark to Sverdr. Such a bequest did not however coincide with the desires of Harold, and between him and Sverdr a constant warfare lasted for several years, until in 1064 they agreed to a peace by which each retained his dominions according to the old established boundaries. The chief motive of Harold in consenting to this arrangement was probably that he might be free to embark on a purpose of wilder ambition, namely, to revive in his own person the old Scandinavian sovereignty of England which had ended with the death of Harthacnut. The story goes that he was instigated to the enterprise by a visit from Toftig, the exiled earl of Northumbria, but whether that be so or not, he in 1065 set sail for England with an immense fleet, which carried his wife Ellsolf, his son Olaf, his treasures, and more than half of all his fighting men. After touching at Orkney, where he left his wife, he proceeded southwards to the Tyne, and was there joined by Toftig and by a contingent of troops from Malcolm of Scotland. From the Tyne they sailed southwards along the coast of Yorkshire, stopping at intervals to ravage the country for provisions, and after proceeding up the Humber east anchor on the left bank of the Ouse near the village of Riccall. Leaving a detachment under his son Olaf to guard the fleet, Harold along with Toftig marched with a great force towards York, and, defeating the Northumbrians with heavy loss at Fulford on September 20th, reached the south end of the city on September 24th. Meanwhile Harold of England, having heard of the Norse invasion, was marching northwards from London day and night with an immense army, and passing through York on the day after its surrender, he

appeared suddenly on the afternoon before the Norsemen encamped at Stamfordbridge. Taken by surprise, the Norsemen fought nevertheless with stubborn courage and fierce energy, but though the battle was for some time doubtful it ended at nightfall in their total overthrow, with a slaughter so enormous that the great majority of them lay dead upon the field. Toftig was slain and also Harold Harthacnut himself, who, towering head and shoulders above all his warriors, was inflicting death on all who dared to meet him, till struck by an arrow in the windpipe he received the wound which laid him low. According to some writers his body ultimately found burial in Norway.

HAROLD IV., king of Norway, surnamed Gille, said to be the stout son of Gylle Kist, that is, Servant of Christ, came about the year 1127 to Norway with his mother, an Irishwoman, and claimed to be recognized as the son of King Magnus Barefoot and half-brother of the reigning Sigurd. Sigurd consented to acknowledge the relationship on condition that Harold did not claim any share in the government during his lifetime or that of his son Magnus. This agreement Harold honourably kept during the lifetime of Sigurd, but after his death in 1130 he got himself chosen king of the half of the country, and after several battles took Magnus prisoner, put out his eyes, and confined him in a convent. Harold now reigned as sole king till 1136, when he was murdered in his sleep by Slomdiaken, another bastard son of Magnus Barefoot.

For the Norwegian Harold, see the *Harthacnut* of *Samuel Starkun*, translated into English by Samuel Lang, London, 1811, *Samuel's Saga*, 2 vols., Oxford, 1878, *Osborne's Early Kings of Norway*, London, 1871, and also, in Harold Harthacnut, *Prominent Norwegian Kings*, vol. vi.

HAROLD I., surnamed Harefoot, king of England, illegitimate son of Canute and Alfgiva of Northampton, was on the death of Canute in 1035 chosen by the witan overlord of England and king of the provinces north of the Thames, and in 1037 he became king of England, when the people of Wessex offered him their crown on Harthacnut's refusing to come to England to accept it. In the beginning of Harold's reign Alfred, son of Ethelred, landed in Wessex, with the purpose it is said of asserting his claims to its sovereignty, but, either without the knowledge of Earl Godwine, or with his connivance, he was seized by the agents of Harold and put to death with cruel tortures. Harold also banished Queen Emma from the kingdom. The only other events of importance in his reign are invasions of the Welsh and Scots, which were, however, without effectual results, and in the case of the Scots who laid siege to Dunham ended in defeat with heavy loss. Harold died at Oxford, March 10, 1040. It is affirmed by some that Harold made no pretensions to a Christian belief, but this seems an exaggeration, for, whatever may have been his own previous opinions, he appears to have conformed generally to the recognized religious customs, and there was one instance at least in which he redressed a wrong done by others to the church.

HAROLD II., king of the English, was the second son of Earl Godwine and his Danish wife Gytha, the sister of Earl Ulfr. The year of his birth is not accurately fixed, but it must have been about 1022. The choice of his name, like that of some others of his brothers and sisters (see GODWIN), witnesses to the influence of his Danish mother. Both he and his elder brother Sweyn were appointed to earldoms while still very young, seemingly about 1045. Harold's earldom was that of the East-Angles. In 1045 Sweyn, having earned the abbas of the East-Angles, and not being allowed to marry her, threw up his earldom in disgust, and his possessions were divided between his brother Harold and his cousin Earl Beorn, the nephew of Gytha. In 1049 Sweyn came back and sought the recovery of his lands, which was refused by

Harold and Boorn Harold now appears for the first time in command, holding a ship in the fleet commanded by his father. For some unknown cause his ship was transferred to Boorn, which most likely saved Harold's life, for Sweegen presently came and entrapped and slew Boorn, who was buried by Harold. We next hear of Harold in 1051 as accompanying Godwine when he appeared in arms in Gloucestershire. He shared his father's outlawry and banishment at that year, but he chose a different place of shelter, going with his brother Leofwine to Ireland, while Godwine went to Flanders. In 1052 Harold and Leofwine came back. They were opposed by the men of Somerset and Devonshire, whom they defeated at Funchok, and were with him at the assembly which decreed the restoration of the whole family. Harold was now restored to his position of the East Angles, and, on his father's death in 1053, he succeeded him in the greater earldom of the West Saxons.

Harold was now the chief man in the kingdom, and when the older earls Leofno and Siward died, his power increased yet more, and the latter part of Edward's reign was virtually the reign of Harold. But he was the minister of the king rather than his personal favourite. This last place rather belonged to his younger brother Tostig, who on the death of Siward in 1055 received the earldom of the Northumbrians. Two other of Godwine's younger sons, Gythil and Leofwine, also received earldoms in 1057. This last date would seem to have been about the time when the prospect of the crown began to open to Harold. The Æthelung Edward, the son of Edmund Ironside, who had been brought home from Hungary as the intended successor, died that year. So did Edward's nephew Ralph, who, though not really of the kingly house, might possibly have been looked to for lack of a nearer candidate. There was now none of the old stock but Edgiva, son of Edward and his sisters. If then the king should die while Edgiva was still a child, there would be no qualified candidate in the royal house. It would seem as if, from this time, men began to look to Earl Harold as a possible successor to the crown. He is spoken of in a way, and his name is joined with that of the king in a way, which is unusual in the case of an ordinary earl.

The chief events in which Harold appears personally during this time are the wars with the Welsh under their king Gruffydd ap Ilyvelyn. In 1055, in alliance with the banished Earl Ælfgar of Mercia, Gruffydd defeated Earl Ralph and burned Hereford. Harold now drove back the Welsh and restored Hereford, but allowed the restoration of Ælfgar to his earldom. In 1058 he made the pilgrimage to Rome. In 1060 he completed the building of his church at Waltham, and completed the foundation of the college in 1062. In 1063 came the great Welsh war, in which Harold, with the help of his brother Tostig, crushed the power of Gruffydd, who was killed by his own people. Harold now gave Wales to two vassal kings, Bleddyn and Rhirwallon. Both of his wars were accompanied by an extension of the English frontier toward Wales. In 1065 the Northumbrians revolted against then earl Tostig, and chose in his place Morkere, the son of Ælfgar. Harold now acted as mediator between the king and the insurgents, and at last, as the Northumbrians were fully prepared not to receive Tostig again, he agreed to their choice of Morkere and to the banishment of his brother.

Besides these there is one very important event in Harold's life the date of which can only be guessed at. At some time or other between William's visit to England in 1051 and Edward's death at the beginning of 1066, Harold was the guest of Duke William in Normandy, and took some kind of oath to him. This oath the Normans

represented as an act of homage, with a further oath to promote William's succession to the English crown. The tale is told only by the Norman writers, and it is told by them with such contradictions of every kind that no reliance can be placed on any detail. But that there is some truth in the story is proved by the strongest negative evidence. While the contemporary English writers take care, directly or indirectly, to deny all those Norman charges against Harold which were sheer invention, they say not a word as to his alleged oath to William. It seems on the whole most likely that Harold was attacked on the shores of Ponthieu, imprisoned by its Count Guy, and released by the intercession of William. He then helped William in a war with the Bretons, and promised to marry one of his daughters. This was most likely accompanied by an act of homage, such as was often made to any superior or benefactor. Such an oath might, in the ideas of the time, be made to mean a great deal or very little, according to circumstances. The most likely date is 1064. But there is a remarkable statement that Harold took a journey in Gaul with a political object, seemingly that of making alliances with some of the princes of the country, and most likely William's enemies in France, Anjou, and Aquitaine. This was in the year of his Roman pilgrimage. And, as there is no direct evidence for the date of the oath, it is open to any one to put the two things together.

At the beginning of 1066 Edward died. His last act was to recommend Harold for election to the crown. He was accordingly chosen on the day of Edward's death, January 5th, and crowned the next day by Aldred, archbishop of York. But, though he was crowned by the Northumbrian primate, the men of Northumbria at first refused to acknowledge him. They were won over by the new king, who went to York, accompanied by Saint Wulfstan, bishop of Worcester. To secure Edwine and Morkere, he married then sister Edgiva, the widow of the Welsh king Gruffydd. He thus put it out of his power to comply with that part of his engagement to William which is best attested, namely, to marry one of William's daughters. The rest of Harold's reign was taken up with preparations against the attacks of two enemies at once. William challenged the crown, alleging both a bequest of Edward in his favour and the personal engagement which Harold had contracted towards him. This was of course a mere matter of form, and William began to make ready for the invasion of England. Meanwhile the banished Tostig was trying all means to bring about his own restoration. His first, seemingly in concert with William, came in May, and attacked first the Isle of Wight and then Lindsey, but was driven to take shelter in Scotland. From May to September the king kept the coast with a great force by sea and land, but at last provisions failed and the land army was dispersed. Harold then went to London, ready to meet whichever enemy came first. By this time Tostig had engaged Harold Hadrada of Norway to invade England. He accordingly sailed up the Humber, defeated Edwine and Morkere (September 20th), and received the submission of York (September 24th). Harold of England was now on his march northward, on September 25th he came on the Northmen at Stanfordin Bridge beyond York, and won a complete victory, in which Tostig and Harold Hadrada were slain. But two days later (September 27th) William of Normandy landed at Pevensey and (September 28th) occupied Hastings, and laid waste the land. Harold had then to march southward as fast as possible. He gathered his army in London from all southern and eastern England, but Edwine and Morkere kept back the forces of the north. The king then marched into Sussex, occupied the hill of Senlac, now Battle, and awaited the Norman attack. After a vain exchange

of messages, the decisive battle was fought on October 14th. As the English were wholly infantry, while the Normans were strongest in cavalry and archers, Harold's object was simply to hold the hill against all attack. As long as he was obeyed, his tactics were completely successful. But a part of his troops, disobeying his orders, left the hill to pursue, and the English array was broken. The Normans could now get up the hill, and, after a fight which lasted from morning till evening, they had the victory. The king and his brothers Gytha and Lothwine were killed. As Harold was condemned by the pope, William at first refused him Christian burial, and caused him to be buried on the rocks at Hastings. But it seems most likely that he afterwards allowed the body to be removed to Harold's own church at Waltham. The tale which represents Harold as escaping from the battle, living a life of penitence, and at last dying at Chesham, is a mere romance.

Harold left several children, but there is a good deal of uncertainty as to his marriage or marriages. He had two sons by Edith, the Harold and Wulf, but they must have been twins born after their father's death. He had also three sons, Godwine, Edmund, and Magnus, and two daughters, Gytha and Gunhild. It will be seen how strong the Scandinavian element is in these names. These five were not children of Edith, and the sons were grown up, or nearly so, when their father died. They may have been the children of the unknown wife who gave the local history of Waltham represented Harold's body as being found after the battle by a farmer mistaking it for Edith's Swannobah (Swannestock). Some have thought that this Edith is the "Editha pulcra" of Domesday, who appears as the former holder of great estates in the east of England. This, though not unlikely, is quite uncertain, but there seems evidence enough to show that Edith's Swannobah is a real person, and to connect her with Harold's East-Anglian exile. It seems most likely that she was the mother of Harold's earlier children, and that the connection between them was that intermediate state between marriage and concubinage called the Danish marriage, of which we not uncommonly hear in those days.

The character of Harold is blackened with many, but mostly very vague, charges, by the Norman writers. The English, on the other hand, paint him as the perfect model of a ruler. With regard to his accession to the crown, the common charge of usurpation springs from ignorance of the English law of the time. Harold was beyond all doubt regularly nominated by Eadward, regularly chosen by the witan, and regularly crowned by Ealdred. This last point is of importance in those days, when the rite of coronation was deemed of such moment. The Normans try to represent the ceremony as invalid, by saying that Harold was crowned by Sigurd, archbishop of Canterbury, whose canonical position was doubtful. That Harold crowned himself, instead of receiving the ecclesiastical consecration, is a mere fable, arising from a misunderstanding of some of the rhetorical invectives of the Norman writers. It should be noticed that those contemporary writers who speak of Harold as a usurper do so wholly on the ground of the alleged right of William, and of Harold's oath to William. That Harold's accession was a wrong done to young Eadgar is an idea which we first hear of in the next century, when the doctrine of hereditary right had taken firmer root. In Domesday the reign of Harold is passed by, he is regularly spoken of as earl, the doctrine of the Norman lawyers was that William, though of course not full king till his coronation, had the sole right to the crown from the moment of Eadward's death.

The military skill of Harold is plain, both from the Welsh war, when he overcame the mountaineers by making his English soldiers adopt the Welsh tactics, and from his

conduct both at Stamfordbridge and at Senlac. He clearly understood the difference between his two enemies, when it was wise to attack and when it was wise to await the attack. At Stamfordbridge his strategy was perfectly successful, it failed at Senlac only because of the disobedience of part of his army. The best witness to his civil government is the general peace and good order of England during that part of the reign of Eadward which was virtually his reign. When the peace is broken, it is always by the act of others, and Harold is always called on to make the settlement. He appears throughout as singularly mild and conciliating, never pressing hard upon any enemy. The later Norman writers indeed have an elaborate tale which represents Harold and Toctus as enemies from their childhood. But this is mere romance, with no ground in any contemporary writer.

The relations of Harold to the church, always an important feature in the character of a prince of that age, suggest several questions. He is charged in Domesday with several encroachments on ecclesiastical property, chiefly in Herefordshire, and the like charge is brought against him in a deed of Leofric, bishop of Exeter. But it must be remembered that this kind of charge is brought against every leading man of the time, and that we very seldom hear more than one side. The most distinct and detailed charge, that which represents Harold as a wholesale spoiler of the church of Wells, can be refuted, not by showing that it is untrue, but by going back to the charge as brought by the original complainant, Bishop Giso. We find that Harold took nothing from the church, but simply hindered the bishopric from receiving a bequest to which there is some reason for thinking that he may have had a right as earl. On the other hand, Harold appears as the friend and protector of several ecclesiastical bodies, and above all as the founder of Waltham. Here we may remark that, when monks were all the fashion, he preferred the secular clergy. He was the true friend of the best prelate of his time, Bishop Wulfstan, and he espoused on good terms with most of the leading churchmen.

The contemporary authorities are the English Chronicle, the Latin biography of Eadward in Dr Lamb's collection (he gives a splendid paragraph on Harold), and *Historia de Worcester*, on the English side. On the Norman side are the *Bayeux Tapestry*, William of Poitiers, William of Jumièges, *Order of Amiens* (*Chronica de Bello Hastingensi*). In the next century the book *De Rebus Gestis Sancti Canuti* (Walthamstow gives Harold's picture as drawn in his own foundation). The book called *Vita Haroldi* is a mere romance, but contains one or two scraps of authentic tradition, and, like the *Historia de Worcester*, and the *Chronica de Bello Hastingensi*, generally, often gives particular facts, and especially show how the estimate of the events of the 11th century gradually changed. The French life of Eadward in the 14th century was later against Harold. Of the Scandinavian writers, *Nexo Grammaticus* is violent against him, while the biography of Olaf Trygvasson counts him for a saint. All the statements are brought together and examined in Freeman's *History of the Norman Conquest*, vols. i. and ii. The opposite pictures of the earlier writers, Thierry and Pagan, are also worth comparing. (E. A. F.)

HAARON AL RASCHID, more properly Harun er Rashid, "Aaron the Orthodox," was the fifth of the 'Abbaside caliphs of Bagdad. His full name was Harun 'ibn Mohammed ibn Abdallah ibn Mohammed ibn Ali 'ibn 'Abdallah ibn Abbas. He was born at Ray the last day of Dhu'l Heggah, 145 A.H. (20th March 763 A.D.) according to some accounts, and according to others 1st Moharrem 149 A.H. (18th Feb 766 A.D.). Harun al Raschid was twenty-two years old when he ascended the throne. His biographers unanimously speak of him as "the most accomplished, eloquent, and generous of the caliphs," but, though his name is a household word, and few figures stand out more grandly prominent in the history of their times, little is really popularly known about his private life and personal history.

Raschid owed his own succession to the throne entirely to the prudence and sagacity of Yahya 'bn Khalid 'bn Barmek, his secretary,¹ whom, on his accession, he appointed his lieutenant and greatest viceroy. Yahya, upon whom the whole responsibility of the government really devolved, performed his duties with the most consummate ability and judgment. He fortified the frontiers, and repaired all the deficiencies in the administration of the empire. He filled the treasury, made the provinces flourishing and prosperous by encouraging trade and securing the public safety, and in a word brought the caliphate up to the highest pitch of prosperity and glory. He personally superintended and organized the whole system of government. As a minister he was eloquent, wise, accomplished, and prudent, and he was moreover an able administrator, ruling with a firm hand and placing himself able to cope with any emergency that might arise. His generosity was manifest in the extreme and gained for him universal esteem. With a most affable demeanour and great moderation he combined an imposing dignity that commanded universal respect.

In 182 A. H. (798 A. D.) Al Raschid proclaimed his son 'Abdallah as his heir apparent after El Amla, his eldest son, whom he had appointed his successor when only five years old, and gave him the post of viceroy of Khorasani. It was on this occasion that he gave 'Abdallah the name of El Mamun, and conferred on him the one of Jafer, son of Yahya. The historians speak of this act of Raschid's with natural surprise, for he had seen the results of similar policy on the part of his father and of his grandfather, as well as what his brother Hadi had done in his own case.

Yahya, the prime minister, and Jafer, his son, enjoyed so fully the confidence of Haroun al Raschid that they rapidly rose to wealth and power. The great popularity and influence of the Barmek or Barmakide family, however, at length aroused the caliph's jealousy, and to make matters worse he heard that Jafer had secretly married his sister. No sooner had he been made acquainted with the facts than he caused his sister to be put to death, ordered Meardr, his slave and executioner, to bring him Jafer's head, and next murdered his two offending young nephews.

After the fall of the Barmek family the office of prime minister was exercised by Fadhl 'bn Rabi' who had been

¹ According to the Mahometan law of succession the eldest brother or male relative of the reigning monarch is the heir apparent to the throne, and almost all Muslim princes have endeavored to set aside the claims of their relatives in favour of their own children. El Hadi, Haroun's brother, was no exception to the rule, and conceived the idea of stripping Haroun of his rights and proclaiming his own son Y'zid as his successor. Yahya was then Haroun's secretary, and expected to exercise the important office of viceroy if ever his master should mount the throne. Hadi saw that his first step must be to conciliate Yahya, so he therefore took him apart, and having given him a present of 20,000 dinars began to broach the subject nearest his heart. Yahya, however, brought a very strong argument to bear upon the point. "If you do so, Prince of the Faithful," said he, "you will set your subjects an example of breaking an oath and of disregarding a contract, and other people will be bold enough to do the same. But if you leave your brother Haroun in possession of his title of heir apparent, appoint your son Jafer as next in succession to him, it will be much more likely to secure his ultimate accession to the throne." Hadi allowed the matter to rest for some time, but at length paternal affection got the better of him, and he again summoned Yahya to his presence and consulted him, and Yahya urged that if the caliph should die while Jafer was yet a child the chiefs of the imperial family would never recognize the validity of his succession. Hadi having acknowledged the truth of this, Yahya continued, "Remember that this project, in order to better to arrive at the consummation of your wishes, even if your father El Mehdi had not appointed Haroun to succeed you it would be policy on your part to do so, inasmuch as that is the only way to secure the continuance of the caliphate in the family of the Beni Hashem." Raschid ever afterwards acknowledged this as the greatest obligation which he owed to Yahya.

chamberlain to Haroun himself, and to his predecessor Mensur, Mehdi, and Hadi. He held the office of vizier until the death of Haroun al Raschid himself, which occurred at Tus, the birthplace of the celebrated Persian epic poet Firdousi. Al Raschid had set out for Khorasani to put down the insurrection of Rafi' 'bn Leeth 'bn Nasr 'bn Sayyar, who had revolted against his authority, made himself master of Samarcand, and killed the governor of that province. The rising had assumed such alarming proportions that Al Raschid determined to march in person against the rebels. He had not, however, got farther than Tus when he was surprised by death in 193 A. H. (809-10 A. D.).

The reign of Al Raschid was one of the most brilliant in the annals of the caliphate, and the limits of the empire were then more widely extended than at any other period. The greater part of the Eastern world submitted to his laws, and paid tribute into his treasury. Egypt itself was only a province under his sway, and its ruler an officer appointed by himself. No caliph ever gathered round him so great a number of learned men, poets, jurists, grammarians, cadis, and scribes, to say nothing of the wit and musicians who enjoyed his patronage. Haroun himself was an accomplished scholar and an excellent poet. He was well versed in history, tradition, and poetry, which he could always quote on appropriate occasions. His refined and exquisite taste and unending disquisitions, and his dignified demeanour made him an object of profound respect to high and low.

Haroun al Raschid is best known to Western readers as the hero of many of the stories in the *Arabian Nights*, and in Arabic literature he is the central figure of numerous anecdotes and humorous stories. Of his incoherent walks through Baghdad, however, the authentic historians say nothing, and the account of his relations with Charlemagne, of which European historians speak, does not rest on a trustworthy basis. His reign is chiefly remarkable for the fact that a family belonging to the pure Persian ancestry held for so long the reins of power under a caliph whose house was that he was the only one who came of unadulterated Hashimi blood, that of the family from which the prophet of El Islam sprung.

The principal authorities on the history of this period are—1. The Arabic histories of Ibn El Athir, Ibn Khaldun, and the Turkish El Khamsa, while the best European works to consult on the subjects are Gibbon's *Decline and Fall of the Roman Empire*, Osiander's *Islam under the Caliphs of Bagdad*, and Wall's *Geschichte der Chalifen*. (H II P)

HARP, a musical instrument of the string kind, approximating to a triangular form from the strings diminishing in length as they ascend in pitch. While the instrument is of great antiquity, it is yet from northern Europe that the modern harp and its name are derived. The Greeks and Romans preferred to it the lyre in its different varieties, and a Latin writer, Ptolemaeus (vi. 8), describes it in the seventh century of our era as an instrument of the barbarian—*"Romanusque lyra, plaudat tibi barbarus harpa."* This is believed to be the earliest mention of the name, which is clearly Teutonic,—the Old High German "harapha," the Anglo-Saxon "harpe," the Old Norse "harpa." The modern French "harpe" retains the aspiate, in the Spanish and Italian "arpa" it is dropped.

For the origin of the instrument we have to look to Egypt, and the earliest delineations of it there give no indication that it had not existed long before. There are, indeed, representations in Egyptian paintings of stringed instruments of a bow-form which support the idea of the invention of the harp from the tension string of the warrior's or hunter's bow. This primitive looking instrument was played horizontally, being borne upon the performer's shoulder. Between it and the grand vertical harps in the frescos of the time of Rameses III.,

more than 3000 years old, paintings discovered by the traveller Bruce (fig. 1), there are varieties that permit us to bind the whole, from the simplest bow-form to the almost triangular harp, into one family (see fig. 2).

The Egyptian harp had no front pillar, and it, being strung with catgut, the tension and pitch must necessarily have been low. The harps above-mentioned depicted

Fig. 1.

in the tomb at Thebes, assumed from the players to be more than 6 feet high, have not many strings, the one, according to Wilkinson, having ten, the other thirteen. What the accordance was of these strings it would be to no satisfaction to follow Burney and others in trying to recover. We must be content with the knowledge that the old Egyptians possessed harps in principle like our own, the largest having pedestals upon which they bestowed a wealth of decoration, as if to show how much they prized them.

The ancient Assyrians had harps like those of Egypt in being without a front pillar, but differing from them in having the sound-board uppermost, in which we find the early use of soundholes; while the lower portion was a bar to which the strings were tied and by means of which the tuning was apparently effected. What the Hebrew harp was, whether it followed the Egyptian or the Assyrian, we do not know. That King David played upon the harp as commonly depicted is rather a modern idea. Medieval artists frequently gave King David the psaltery, a horizontal stringed instrument from which has gradually developed the modern piano.

The Assyrian, we do not know. That King David played upon the harp as commonly depicted is rather a modern idea. Fig. 2.

The earliest records that we possess of the Celtic race, whether Gaelic or Cymric, give the harp a prominent place and harpists peculiar veneration and distinction. The names for the harp are, however, quite different from the Teutonic. The Irish "clairsheach," the Highland Scotch "clarsach," the Welsh, Cornish, Breton, "telyn," "teletin," "tellen," show no etymological kinship to the other European names. The first syllable in clairsheach or clarsach is derived from the Gaelic "clair," a board or table (sound-board), while the first syllable of telyn is distinctly Old Welsh, and has a tensile meaning; thus resonance supplies the one idea, tension the other.

The literature of these Celtic harps may be most directly found in Bunting's *Ancient Music of Ireland*, Dublin, 1840; Gunn's *Historical Enquiry respecting the Performance on the Harp in the Highlands of Scotland*, Edinburgh, 1807; and R. Jones's *Musical and Poetical Memoirs of the Welsh Bards*, London, 1784. The treatises of Walker, Dailly, and others may also be consulted; but in all these authorities due care must be taken of the bias of patriotism, and the delusive aim to reconstruct much that we must be content to receive as only vaguely indicated in records and old monuments. There is, however, one early Irish monument about which there can be no mistake, the harp upon a cross belonging to the

ancient church of Ullard near Kilkenny, the date of which cannot be later than 830; the sculpture is rude, but the instrument is clearly shown by the drawing in Bunting's work to have no front pillar. This remarkable structural likeness to the old harps of Egypt and Assyria may be accidental, but permits the plausible hypothesis of Eastern descent. The oldest specimen of the beautiful form the Irish harp is now recognized by, with gracefully curved front pillar and sweep of neck (the latter known as the harmonic curve), is the famous harp in Trinity College Dublin, the possession of which has been attributed to King Brian Boroihme. From this mythic ownership Dr Petrie (see essay in Bunting) has delivered it; but he can only deduce the age upon the ground of its ornamentation and heraldry, which fix its date in the 14th century or a little later.

There is a cast of it in South Kensington Museum, accurately described in the catalogue by Mr Carl Engel. The next oldest is in the Highlands of Scotland, the *Clarsach Lunnainach*, or Lamont's Clarsach, belonging to the family of the Dalrymple, which fix its date in the 14th century or a little later. The next oldest is in the Highlands of Scotland, the *Clarsach Lunnainach*, or Lamont's Clarsach, belonging to the family of the Dalrymple, which fix its date in the 14th century or a little later.

FIG. 3.—
Irish (Dalway) Harp.

The compass of their harps to comprise

shirty notes which were tuned diatonically in the key of G, under certain circumstances transposable to C and rarely to D, the scales being the major of these keys. The harp first appeared in the coat of arms of Ireland in the reign of Henry VIII.; and some years after in a map of 1567 preserved in a volume of State Papers, we find it truly drawn according to the outlines of the national Irish instrument. References to the Highlands of Scotland are of necessity included with Ireland; and in both we find another name for the harp, viz., "crut." Bunting particularly mentions the "cinnard crut" (harp with a high head) and the "erom crut" (the curved harp). In the *Ossianic MSS.* of the Dean of Lismore (1613) the word "crut" occurs several times, and in *Neill MacAlpine's Gaelic Dictionary* (1839) which gives the dialect of Inlay, closely related to that of Ulster, the word "crut" is rendered "harp." In Irish of the 6th and 6th centuries (Zenzli) "cithara" is always followed by "crut." True to the old Welsh "crut" is "chrotha Britannica" has been too readily accepted as meaning the half-fiddle half-harp which also bears the name of "crut" or "crowd." An old Welsh harp, not tripple stringed, exists, which bears a great resemblance to the Irish harp in neck, sound-board, and soundholes. The inference is fair that this was the form, although dimensions may have materially differed, of the Irish "erom crut," while the tripple string harp with its elevated neck might be the form of the "cinnard crut." But this does not imply derivation of the harp of Wales from that of Ireland or the reverse. There is really no good historical evidence, and there may have been a common or distinct origin on which etymology only can throw light. The Welsh like the Irish harp was often an hereditary instrument to be preserved with great care and veneration, and was the property of the family, who were alike the poets, musicians, and historians. A slave was not allowed to touch a harp, and it was exempted by the Welsh laws from seizure for debt. The old Welsh harp appears to have been at one time strung with horsehair, and by the Elizabethan laws the pupil spent his noviciate of three years in the practice of a harp with that stringing. The comparatively modern Welsh tripple harp (fig. 4) is strung with gut. It has a rising neck as before stated, and three rows of strings; the outer rows tuned diatonic, the centre one chromatic for the sharps and flats, Jones gives it 96 strings and a compass of 5 octaves and was not, from violoncello

FIG. 4.—Welsh
Tripple Harp.

As in all Celtic harps, the left is the treble hand, and in the middle harp there are 27 strings on this side, the right or bass hand having 17, and the middle or chromatic row 31.

Turning to the modern harp, the first pattern of it is discovered in German and Anglo-Saxon illuminated MSS as far back as the 9th century. A diatonic instrument, it must have been common throughout Europe, as Ottaviani, Fra Angelico, and other famous Italian painters depict it over and over again in their masterpieces. No accidental semitones were possible with this instrument, unless the strings were shortened by the player's finger. This lasted until the 17th century, when a Tyroler maker adapted hooks (perhaps suggested by the fretted or banded clavichord) that, sewed into the neck, could be turned downwards to fix the desired semitones at pleasure. At first, sometimes about 1720, Hochbrucker, a Bavarian, invented pedals that, acting through the pedestal of the instrument, governed by mechanism the stopping, and thus left the player's hands free, an indisputable advantage, and it became possible at once to play in no less than eight or nine scales. By a succession of improvements, in which two Frenchmen named Cousineau took an important part, the various defects inherent in Hochbrucker's plan became ameliorated. The pedals were doubled, and the tuning of the instrument being changed from the key of E♭ to C, it became possible to play in fifteen keys, thus exceeding the power of the keyboard instruments, over which the harp has another important advantage in the simplicity of the fingering which is the same for every key.

It is to Sebastian Eard we owe the perfecting of the pedal harp (Fig. 5), a triumph he gained in Paris by university studies begun when he adopted a "fork" mechanism in 1780 and ended in 1810 when he had attained complete success. The mechanical perfection of Eard's apparatus must be seen to be appreciated. The pedals give the extent of movement the disks perform from which the studs project that stop the strings, as it may be required to raise the string in pitch a half tone or a whole tone. Eard's merit was not confined to this improvement only, he modified the situation of the comb that controls the mechanism, and constructed the sound-body of the instrument upon a modern principle more advantageous to the tone.

Notwithstanding these improvements and the great beauty of tone the harp possesses, the domestic use of it has for years past been declining. The great cost of a good harp, and the trouble to many amateurs of tuning, may have led to the supplanting of the harp by the more convenient and useful pianoforte. With this comes naturally a diminution in the number of solo-players on the instrument. Were it not for the increasing use of the harp in the orchestra, the color of its tone having attracted the masters of instrumentation, so that the great scores of Meyerbeer and Gounod, of Berlioz, Liszt, and Wagner are not complete without it, we should perhaps know little more of the harp than of the dulcimer, in spite of the efforts of distinguished virtuosi whose devotion to their instrument maintains its technique on an equality with that of any other, even the most in public favour.

See, in addition to the works already referred to, Engel's *Manual Instruments*, in the *Siach Encyclopædia Musæus*, 1874, and the articles "Harp," in Rees's *Cyclopædia*, written by D. Burney, in Stainer and Barrett's *Dictionary of Musical Terms*, 1876, and in Grove's *Dictionary of Music and Musicians*, 1879. (A. J. H.)

HARPER'S FERRY, a post village of Jefferson county, West Virginia, United States, is grandly situated at the foot

of Bolivar heights and at the confluence of the Shenandoah and Potomac rivers, where they intersect the Blue Ridge, 15 miles N.W. of Washington. It is the junction point of the Baltimore and Ohio and the Winchester and Potomac railways, and the Ohio and Chesapeake canal passes along the Maryland side of the Potomac river. The village since the civil war has been in a decaying condition. It is the seat of Storer college, for students of colour. Previous to the war Harper's Ferry contained an extensive arsenal and armory, and during the war it was the scene of several exploits which have given it a name in history. On the 16th October 1859 it was seized by John Brown, the celebrated abolitionist, and a small handful of followers, but as he was unsupported by a rising of the slaves he was overpowered on the morning of the 18th and taken prisoner. On the 18th April 1861 it was captured by the Confederates, who on evacuating it in the following June destroyed the arsenal and armory and the bridge across the Potomac. The village was afterwards held by a Union garrison of 12,000 men, who, however, on the 15th September 1862, after a brave resistance of several days, surrendered to a strong Confederate force under Jackson and A. P. Hill. After the battle of Antietam, on the 17th of the same month, it was recaptured by the army of the Potomac under General McClellan, who left a strong garrison in the place. In June 1863 it was again handed over to the Confederates on their march to Pennsylvania. After the defeat at Gettysburg, the town again fell into the hands of the Federal troops, who held it until the demonstration against Washington in July 1864. After the battle of Monocacy on July 9th it was occupied by the United States forces, and held by them until the end of the war. The most flourishing part of the town was nearly destroyed by a flood in the Shenandoah, October 1878. The population is about 3000.

HARPIES, or HARPYÆ, a word from the root seen in *ἀρπάζω*, to snatch, are in Homer merely the embodiment of the rapacious power of violent winds. When a man has disappeared in a sudden and inexplicable fashion, it is said that the Harpies have carried him off, and the words *ἀρπάζω* and *δελία* are used indifferently (*Od.* xiv 371 with 737, and *xx* 68 with 77) to indicate the agent in his sudden disappearance. But *Od.* *xx* 63-5 shows that the winds were conceived as carrying the man away to the banks of Oceanus, in other words, to the sky. So it is said (*Il.* *xx*, 208, *Schol.* *Il.* *xx* 214) that a *θάρψας δελία* carried off Ganymede to heaven. There can be no doubt that the wind was by the primitive Indo-Germanic people considered to be the agent that carried off the souls of the dead to dwell with their fathers in heaven, and that this idea appears in the *Odyssey* (also *Il.* *vi* 315) in a more fanciful form. As messengers of Zeus the Harpies are called *ἄδω δαίμονες* (*Ap.* *Rh.* i 269). In some accounts a Harpy is said to have been by Poseidon the mother of the horse Arion, and another form of the same name appears in *Il.* xvi 148, where the harpy Podage, grazing in a meadow by the stream of Oceanus, bears to Zephyrus (the fruitful generative wind) the two horses of Achilles. This myth, which occurs in numberless forms, has been explained in article *GOOZONS*, from which it is clear that ultimately Harpy is another epithet, like *Gorgo* and *Erynys*, of the swift, sudden, violent thunder-storm of a southern country. It is therefore with good ground that the three forms are compared by *Æschylus* (*Eum.* 48). The function of snatching away mortals to the other world leads up to the duty which the Greeks came to assign to the Erinyes of punishing and punishing certain kinds of offenders (see *FURIES*). In *Od.* *xx* 68 *sg.* it is related that the orphan daughters of Pandarus grew up under the care of the gods, but when Aphrodite went to Olympus to beg to perfect their life by a marriage, the Harpies carried them off and

FIG 5.—Modern
Pedal Harp

delivered them to the Erinyes. In these two daughters, one of whom is the nightingale (*Od.* x. 518), and the other probably the swallow (*v. Sonne in Kuhn's Zeitschrift*, x., 121), we recognize the spring growing up in beauty till it is suddenly snatched away from the earth by the storms of autumn. Hesiod (*Theog.*, 267) says that the Harpies, Aello and Ocypete, winged goddesses with beautiful locks, are the daughters of Thanos and Electra. Other accounts make them children of Poseidon or of Phineus, always the son in some form; while a third, Celeno, is often added to their number. As we come down later in literature, a more hateful and repulsive character attaches to the Harpies. This is especially seen in the myth of the blind king Phineus, the sun-god in the dark winter months, tormented by the Harpies, where the transforming fancy of the poets can be traced more and more. Hesiod related (*Strabo*, vii. 463) that the Harpies carried off Phineus to the land of the Glastophagi, a mythic people, who represent like the Hyperboreans or the Phaeacians the race of the dead, the Pitris or Mnæes. The myth was incorporated as an episode in the tale of the Argonauts, and is then imitated by Virgil with still more nauseous details (*Æn.* iii. 219). On the so-called Harpy monument from Lycia, now in the British Museum, they appear as winged figures, the body like that of a bird with the head and bust of a woman. They are carrying off small figures, probably departed souls.

HARPOCRATES, originally an Egyptian deity, was adopted by the Greeks, and became in later times an object of worship both to Greeks and Romans. In Egypt Harpa-khrati, Horus the child, was one of the forms of Horus, the sun-god, the child of Osiris (see *Ermyr*, vol. vii. p. 1717). Hence Herodotus (ii. 144) considers him the same as the Greek Apollo. He was said by the Greeks to have been born with his finger on his lips, and is thus represented in statues. As the god of silence he became a favourite deity among the later mystic schools of philosophy. Festivals with certain mysterious rites were celebrated in his honour.

HARPY, a large diurnal bird of prey, so named after the mythological monster of the classical poets,—the

to Brazil. Though known for more than two centuries, its habits have come very little under the notice of naturalists, and what is said of them by the older writers must be received with some suspicion. A cursory inspection of the bird, which is not unfrequently brought alive to Europe, its size, and its enormous bill and talons, at once suggest the vast powers of destruction imputed to it, and are enough to account for the stories told of its ravages on mammals,—aloes, fawns, poodles, and spider-monkeys. It has even been asserted to attack the human race. How much of this is fabulous there seems no means at present of determining, but some of the statements are made by venacious travellers—D'Orbigny and Tschudi. It is not uncommon in the forests of the isthmus of Panama, and Mr. Salvin says (*Proc. Zool. Society*, 1864, p. 368) that its flight is slow and heavy. Indeed its Owl-like visage, its short wings and soft plumage, do not indicate a bird of very active habits, but the weapons of offence with which, as above stated, it is armed, show that it must be able to cope with vigorous prey. Its appearance is sufficiently striking—the head and lower parts, except a pectoral band, white, the former adorned with an erectile crest, the upper parts dark grey banded with black, the wings dusky, and the tail barred; but the huge bill and powerful scouletated legs must of all impress the beholder. The precise affinities of the Harpy cannot be said to have been determined. By some authors it is referred to the Eagles, by others to the Buzzards, and by others again to the Hawks; but possibly the first of these alliances is the most likely to be true. (A. N.)

HARRIER. See DOO.

HARRIER, or HUN-HARRIER, name given to certain birds of prey which were formerly very abundant in parts of the British Islands, from their habit of harrying poultry. The first of these names has now become used in a generic

Harpy.

Thrausastus harpyia of modern ornithologists,—an inhabitant of the warmer parts of America from Southern Mexico

Hen-Harrier (Male and Female).

sense for all the species ranked under the genus *Circus* of Lacépède, and the second confined to the particular species which is the *Falco cyaneus* of Linnaeus and the *Circus cyaneus* of modern ornithologists.

On the wing Harriers have much resemblance to Buzzards, using the same flapping stroke of the pinions, and wheeling or sailing aloft as they fly. One European species indeed, *C. ceruginosus*, though called in books the Marsh-Harrier, is far more commonly known in England and Ireland as the Moor-Buzzard. But Harriers are not, like Buzzards, arboreal in their habits, and always affect open country, generally, though not invariably, preferring marshy or swampy districts for markets and from form a great part of their ordinary food. On the ground their carriage is utterly unlike that of a Buzzard, and their long wings and legs

render it easy to distinguish the two groups when taken in the hand. All the species also have a more or less well-developed ruff or fall of small, thickest feathers surrounding the lower part of the head, nearly like that seen in Owls, and accordingly many systematists consider that the genus *Otus*, though undoubtedly belonging to the *Falconidae*, connects that Family with the *Strigidae*. No osteological affinity, however, can be established between the *Harrises* and any section of the Owls, and the superficial resemblance will have to be explained in some other way. *Harrises* are found almost all over the world,¹ and fifteen species are recognised by Mr Sharpe (*Cat Birds Brit Museum*, i, pp 50-73). In most if not all the *Harrises* the sexes differ greatly in colour, so much so that for a long while the males and females of one of the commonest and best known, the *O. cyaneus* above mentioned, was thought to be distinct species, and was or still are called in various European languages by different names. The error was maintained with the greater persistency since the young males, far more abundant than the adults, wear much the same plumage as their mother, and it was not until after Montagu's observations were published at the beginning of the present century that the "Ringtail," as she was called (the *Fulco pygmaeus* of Linnaeus), was generally admitted to be the female of the "Hen Harrier." But this was not Montagu's only good service as regards this genus. He proved the hitherto unexpected existence of a second species,² subject to the same diversity of plumage. This was called by him the Ash coloured Falcon, but it now generally bears his name, and is known as Montagu's Harrier, *O. cinereus*. In habits it is very similar to the Hen Harrier, but it has longer wings, and its range is not so northerly, for while the Hen Harrier extends to Lapland, Montagu's is but very rare in Scotland, though in the south of England it is the most common species. *Harrises* indeed in the British Islands are rapidly becoming things of the past. Their nests are easily found, and the birds when nesting are easily destroyed. In the south-east of Europe, including also to the Cape of Good Hope and to India, there is a fourth species, the *O. nesiotes* of some writers, the *O. pallidus* of others. In North America *O. cyaneus* is represented by a kindred form, *O. hudsonius*, usually regarded as a good species, the adult male of which is always to be recognized by its rufous markings beneath, in which character it rather resembles *O. cinereus*, but it has not the long wings of that species. South America has in *O. cinereus* another representative form, while China, India, and Australia possess more of this type. Thus there is a section in which the males have a strongly contrasted black and grey plumage, and finally there is a group of large forms allied to the European *O. an cyaneus*, wherein a grey dress is less often attained, of which the South African *O. carolinus* and the New Zealand *O. gouldi* are examples. (A N)

HARRINGTON, JAMES (1611-1677), a distinguished writer on the philosophy of government, was sprung from an old family in Rutlandshire, and was born in January 1611. He received a careful education, and in his eighteenth year entered Trinity College, Oxford, as a gentleman commoner. One of his tutors was the famous Chillingworth. At the close of his university career he set out to travel on the Continent, and proceeded first to Holland, where he spent several years. He served some time in the Dutch army, and enjoyed the friendship both of the prince

of Orange and of the queen of Bohemia. After visiting France and Italy, he returned to England and lived in retirement till 1646, when he was named one of the gentlemen of the bed-chamber to Charles I, who was at that time being conveyed south from Newcastle as prisoner of the parliament. Though republican in his ideas, Harrington secured the confidence and respect of the king, who showed strong personal regard for him. On the removal of Charles to the Isle of Wight, Harrington was prevented from accompanying him, and was for a short time put in confinement because he would not swear to refuse assistance to the king should he attempt to escape. His feelings of respect led him also to accompany Charles to the scaffold in the following year.

After Charles's death Harrington once more withdrew into private life and devoted his time to the composition of his work on the theory of the state, afterwards published under the title of *Oceana*. The nature of his views was well known, and, as they pleased neither republicans nor royalists, the work was naturally regarded with some suspicion. By order of Cromwell the *Oceana* was seized when passing through the press. Harrington, however, managed to secure the favour of the Protector's favourite daughter, Miss Claypole, the work was restored to him, and appeared in 1656, dedicated to Cromwell. The views embodied in *Oceana*, particularly that bearing on the vote by ballot and rotation of magistrates and legislators, Harrington and others who formed a club called the "Dio" endeavoured to push practically, but with no success. In December 1661, by order of Charles II, Harrington was arrested on a charge of conspiracy, and though there seem to have been no sufficient grounds for the accusation, he was thrown into prison. Despite his repeated request no public trial could be obtained, and when at length he endeavoured to protect himself by claiming the right of *habeas corpus*, he was secretly removed to a small island off Plymouth. There his health completely gave way, and his mind appeared to be affected. By careful treatment he was restored to bodily vigour, but it is supposed that his mind never recovered its tone. After his release he married,—at what date does not seem to be precisely known. He died September 11, 1677.

Harrington's books consist of the *Oceana*, and of papers, pamphlets, aphorisms, even treatises, in support and defence of the *Oceana*. The *Oceana* is not a philosophical romance, it is a hard, prolix, and in many respects heavy exposition of a new method for constituting civil society. The details are elaborated with infinite care, even the salaries of officials being computed, but the important or leading ideas in the book are two in number, with two practical precepts following from them. The first is that the determining element of power in a state is property generally, property in land in particular, the second is that the executive power ought not to be vested for any considerable length of time in the hands of the same men or class of men. As a practical corollary to his first proposition Harrington recommends an agrarian law, limiting the portion of land held to that yielding a revenue of £2000, and consequently insisting on particular modes of distributing landed property. As a practical maxim following from the second he lays down the rule of rotation by ballot. A third part of the executive, senate, or whatever it might be, are voted out by ballot every year (not being capable of being elected again for three years). Harrington explains very carefully how the state and its governing parts are to be constituted by his scheme, and *Oceana*, undoubtedly contains many valuable ideas. As a book, however, it is unfortunately dull.

The *Works* were edited by Toland in 1706, Toland's edition, with additions by Bury, appeared in 1747, and again in 1771.

HARRINGTON, SIR JOHN See HARRINGTON

¹ The distribution of the different species is rather curious, while the range of some is exceedingly wide,—one, *O. maculosa*, seems to be limited to the island of Reunion (Bourbon).

² A singular mistake, which has lately been productive of further error, was made by Albin, who drew his figure (*Hist. Birds*, n, pl. 5) from a specimen of one species, and coloured it from a specimen of the other.

HARRIOT, or HARRIOTT, THOMAS (1560–1621), an English mathematician and astronomer, was born at Oxford in 1560. After studying at St Mary's Hall, Oxford, where he took his bachelor's degree in 1579, he became tutor to Sir Walter Raleigh, who in 1585 appointed him to the office of geographer to the second expedition to Virginia. Harriot published an account of this expedition in 1588, and the work was afterwards reprinted in Hakluyt's *Voyages*. On his return to England after an absence of two years, he resumed his mathematical studies with zeal and success, and having made the acquaintance of Henry Percy, earl of Northumberland, distinguished for his patronage of men of science, he received from him a yearly pension of £120. He died at London 2d July 1621, after having suffered much from a cancer in the lip, occasioned in it is supposed by a habit he had contracted of holding in his mouth instruments of brass often charged with verdigris. A manuscript of Harriot's entitled "Lphemeris Chyrometria" is preserved in Sion College, and his *Artis Analyticae Praxis ad Aequationes Algebraicas resolvendas* was published at London in 1631. An account of his contributions to the science of algebra will be found in the article ALGEBRA, vol. i. p. 514, and Wallis's *History of Algebra* (1686) may also be consulted. From some papers of Harriot's discovered in 1784 it would appear that he had either procured a telescope from Holland, or divined the construction of that instrument, and that he conceived in point of time with Galileo in discovering the spots on the sun's disk.

HARRIS, JAMES (1709–1780), a distinguished English writer on the subject of grammar, was born at Salisbury on the 20th of July 1709. He received his early education at Salisbury, whence he was removed to Oxford at the age of sixteen, and, having passed the usual number of years as a gentleman commoner at Wadham College, he was entered at Lincoln's Inn as a student of law, though not intended for the bar. When he had attained his twenty-fourth year his father died, and this event, having at once freed him from all control, and placed him in the possession of an independent fortune, enabled him to exchange the study of law for other pursuits more congenial to his taste. The decided bent of his mind had always been towards the Greek and Latin classics, and to the study of these he now applied himself with unremitting assiduity during a period of fourteen or fifteen years. The first fruit of this lengthened course of application was a volume which he published in 1744, containing three treatises—one on art, another on music, painting, and poetry, and a third on happiness. In 1751 appeared the work by which he is best known, *Hermes*, a philosophical inquiry concerning universal grammar. Although *Hermes* had considerable reputation in its day as a treatise on grammar, it must now be regarded as antiquated, and even as erroneous in conception. It is not so much a work on grammar as an attempt to force upon grammatical forms a strictly logical significance, to discover the groundwork of all grammars by analysing the thoughts to be expressed in words. This method, as we now recognize, is incapable of throwing light upon the oral structure and growth of language and grammatical forms. In 1775 Harris published his *Philosophical Arrangements*, part of a larger work which he had meditated, but did not complete, on the peripatetic logic. It is in fact a commentary on Aristotle's categories, and an attempt to discuss problems of more recent philosophy by the Aristotelian notions. The *Philosophical Inquiry* is a pleasantly written but slight work on the principles of literary criticism and style. It is the least pedantic of all his works. Harris died in December 1780. His works were collected and published in 3 vols., 1801, by his son, Lord Malmesbury, who prefixed a brief biography.

HARRIS, JOHN, D.D. (c. 1687–1719), an English writer, best known as the editor of the *Lexicon Technicum*, which ranks as the earliest of the long line of English encyclopedias, and as the compiler of the *Collection of Voyages and Travels*, which passes under his name. He was educated at St John's College, Cambridge, where he took his B.A. degree in 1687, and proceeded M.A. in 1690. Having entered the church, he was soon presented to the rectory of Winchelsea in Sussex, and as early as 1698 he was in sufficient repute as a learned divine to be entrusted with the delivery of the seventh series of the Boyle lectures—*Atheistical Objections against the Being of God and His Attributes fairly considered and fully refuted*. Between 1702 and 1704 we find him lecturing on mathematics on the foundation of Charles Cox, and advertising himself as a mathematical tutor at Amen Corner. The friendship of Sir William Cowper, afterwards lord chancellor, soon after raised him to a much higher position. Besides receiving the office of private chaplain to Sir William, he was presented in 1708 with a prebend in Rochester Cathedral, and appointed to the rectory of the united parishes of St Mildred, Bread Street, and St Margaret Moses. In this position he showed himself an ardent supporter of the Government, and got into a bitter quarrel with the Rev. Charles Humphreys, who afterwards was chaplain to Dr Sacheverell. Harris was one of the early members of the Royal Society, and for a time acted as vice-president. Besides his contributions to the society's *Transactions*, and the two important works by which he is best remembered, he published a number of treatises on mathematics and occasional sermons, and at his death on September 7, 1719, he was busy completing an elaborate *History of Kent*, of which the first volume had just left the press. He is said to have died in poverty brought on by his own bad management of his affairs. There is only one good account of his life, that by Nichols in the *Literary Anecdotes*, vol. ix., and this even, owing to scarcity of materials, is strangely defective.

HARRIS, JOHN (1802–1886), divine and theologian, was born at Upton, in Devonshire, March 8, 1802. At the age of fifteen he joined the Independent Church, and began to preach to the inmates of the neighbourhood as a member of the Bristol Itinerant Society. After studying at the Independent college at Hoxton he was in 1827 ordained pastor of a small congregation at Epsom. There in 1836 he wrote his essay, *Mannism, or Covenantness the Sin of the Christian Church*, which won a prize of 100 guineas offered by Dr Conquest, and brought its author into notice, thirty thousand copies being sold within a few years. In 1838 he received the degree of doctor of divinity from Brown University, America, and was appointed president and professor of theology in Chestnut college, and in 1850, when the Independent colleges at Highbury, Homenet, and Coward, near London, were united, Dr Harris was elected principal of the New College thus formed. He died December 21, 1886.

Besides *Mannism*, he wrote the *Great Teacher* (1835), two prize essays, *St Clement* (1837) and *The Great Commission* (1842), and *Contributions to Theological Science* (1843), *From Birth to Death* (1847), *Adam Primordial* (1848), and *Put to sleep* (1855), from the beginning of a series, intended to illustrate the history of man from a theological point of view, but interrupted by his death.

HARRIS, SIR WILLIAM SNOW (1791–1867), a distinguished physician, was descended from an old family of Plymouth solicitors, and was born there 1st April 1791. He received his early education at the Plymouth grammar-school, and completed a course of medical studies at the university of Edinburgh, after which he established himself as a general medical practitioner in Plymouth. On his marriage in 1824 he resolved to abandon his profession on account of its duties interfering too much with his favourite

study of electricity. As early as 1820 he had invented a new method of arranging the lightning conductors of ships, the peculiarity of which was that the metal was permanently fixed in the masts and extended throughout the hull, but it was only with great difficulty, and not till nearly thirty years after wards, that his invention was adopted by the Government for the royal navy. In 1826 he read a paper before the Royal Society "On the Relative Powers of various Metallic Substances as Conductors of Electricity," which led to his being elected a member of the society in 1831. Subsequently, in 1834, 1836, and 1839, he read before the society several valuable papers on the elementary laws of electricity, and he also communicated to the Royal Society of Edinburgh various interesting accounts of his experiments and discoveries in the same field of inquiry. In 1835 he received the Copley gold medal from the Royal Society for his papers on the "Laws of Electricity by High Tension," and in 1839 he was chosen to deliver the Bakerian Lecture. Meanwhile, although a Government commissioner had recommended the general adoption of his conductors in the royal navy, and the Government had granted him an annuity of £300 "in consideration of services in the cultivation of science," the naval authorities continued to offer various objections to his invention to aid in its moving these he in 1843 published his work on *Thunder storms*, and also about the same time contributed a number of papers to the *Naturalist* to illustrate the damage by lightning. His system was actually adopted in the Russian navy before he succeeded in removing the prejudices against it in England, and in 1845 the emperor of Russia in acknowledgment of his services presented him with a valuable ring and a superb vase. At length, every doubt as to the efficiency of his system having been removed, he received in 1847 the honour of knighthood, and subsequently a grant of £5000. After succeeding in introducing his invention into general use Harris resumed his labours in the field of original research, but as he failed to realize the advances that had been made by the new school of science his application resulted in no discoveries of much value. His manuals of *Electricity*, *Galvanism*, and *Magnetism*, contributed to Woele's rudimentary series, were however written with great clearness, and passed through several editions. He died 22d January 1867, while having in preparation a *Treatise on Frictional Electricity*, which was published posthumously in the same year, with a memoir of the author by Charles Tomlinson, F.R.S.

HARRISBURG, a city of the United States, capital of Dauphin county and of the State of Pennsylvania, is beautifully situated on the east bank of the Susquehanna river, on the Pennsylvania canal, and at the junction of several railways, 129 miles by rail N. of Washington and 105 W. by N. of Philadelphia. The river, which is here a mile in width, is crossed by two bridges, one of which is for the use of the railways. Two other bridges of great beauty and strength span the river in view of the State-house. The State buildings, dating from 1819, occupy an eminence in the centre of the busiest portion of the city, and consist of the State capitol, 180 feet long by 80 feet wide, with a circular portico in front supported by six Ionic columns and surmounted by a dome, and, on two sides of the capitol, smaller buildings uniform in design, containing the executive chamber, the State treasury, and various other offices. The capitol park contains a monument to those who died in the Mexican war. Among the other public buildings are the county court house, the State arsenal, the county prison, and the opera house. Harrisburg is a bishop's see of the Roman Catholic Church. It is well provided with academies and schools, and possesses about 80 churches, several of which are costly and ornamental edifices. It is also the seat of

the State library of over 40,000 volumes. Among the benevolent institutions are the city hospital, the home for the friendless, and the State lunatic hospital. An abundant water supply is obtained from the river. Coal and iron are largely wrought in the neighbourhood, and the great facilities of communication both by canal and railway have enabled the city to become one of the centres of the iron trade. It possesses large iron-foundries, manufacturing of steel, machines, boilers, engines, carriages, nails, files, galvanised iron, blooms, scrap, and shoes, rolling-mills, saw and planing mills, flour-mills, cotton-mills, potteries, tanneries, and breweries. The inhabitants in 1860 numbered 13,405, and in 1870, 23,104. The population of the city proper for 1880 is estimated at 31,700, and that of the suburbs at 4900, making a total of 36 600.

Harrisburg received its name from John Harris, an Englishman who settled on the site of the town in 1726, and whose son established a ferry over the Susquehanna in 1765. The town was founded in 1765 under the name of Harrisburg, which was afterwards changed to Lousiburg, in 1791 it was incorporated under its present name, in 1812 it became the capital of the State, and in 1860 it was made a city.

HARRISON, JOHN (1693-1776), an eminent mechanic, was the son of a carpenter, and was born at Faubly, near Pontefract, in Yorkshire, in the year 1693. Thence his father and family removed in 1700 to Hallow, in Lancashire. Young Harrison at first learned his father's trade, and worked at it for several years, at the same time occasionally making a little money by land measuring and surveying. The strong bent of his mind, however, was towards mechanical pursuits, and this showed itself especially in endeavours to improve the construction of clocks and watches so as to render them more accurate measures of time. He soon learned that, to enable a clock to keep accurate time, the pendulum must be so constructed as to preserve the distance between the point of suspension and centre of oscillation invariable, notwithstanding the expansion and contraction of the rod caused by changes of temperature. To accomplish this Harrison devised, in 1726, his ingenious "gridiron pendulum," which consists in having the bob suspended by a series of parallel rods, alternately of steel and brass, so arranged that the downward expansion of the steel rods from change of temperature is exactly compensated for by the upward expansion of the brass rods. This principle of compensation, modified to suit particular cases, is now applied to all good watches and chronometers. Another ingenious improvement in clockmaking devised by Harrison was his recoil escapement, which obviated the necessity of keeping the pallets well oiled. He was led to invent this, as he himself tells us, by having on one occasion had to go a long distance to set right a turret clock which had stopped simply from want of oil on the pallets. This escapement, although answering admirably the intended purpose, is rather too delicate to be adopted in ordinary practice. Harrison was also the first to employ the commonly used and effective form of "going tatchet," which is a spring arrangement for keeping the watches going at its usual rate during the interval of being wound up.

In Harrison's time the Government of the country had become fully alive to the necessity of determining more accurately the longitude at sea. For this purpose they passed an Act in 1714 offering rewards of £10,000, £15,000, and £20,000 to any who should construct chronometers that would determine the longitude within 60, 40, and 30 miles respectively. Harrison applied himself vigorously to the task, and in 1735 went to the Board of Longitude with a watch which he also showed to Halley, Graham, and others. Through their influence he was allowed to proceed in a king's ship to Lisbon to test

it, and the result was so satisfactory that the commissioners gave him £2500 to carry out further improvements. Harrison worked at the subject with the utmost perseverance, and, after making several watches, went up to London in 1761 with one which he considered very perfect. His son William was sent on a voyage to Jamaica to test it, and, on his return to Portsmouth in 1762, the watch was found to have lost only 1 minute 54½ seconds. This was surprisingly accurate, as it determined the longitude within 18 miles, and Harrison claimed the full reward of £20,000. After some further trials £10,000 of it was paid to him in 1765, and the remainder in 1767, after he had written such a description of his instrument as would enable other artists to copy it. Harrison died in 1776, at the age of eighty-two. His want of early education was felt by him greatly throughout life. He was unfortunately never able to express his ideas clearly in writing, although in conversation he could give a very precise and exact account of his many intricate mechanical contrivances. He wrote a book entitled *Description concerning such Mechanism as will afford a New or True Measurement of Time*.

HARRISON, WILLIAM HENRY (1773-1841), ninth president of the United States, third son of Governor Benjamin Harrison, was born at Berkeley, Charles county, Virginia, February 9, 1773. In 1792 he joined the army with the commission of ensign, and in the following year he became lieutenant and acted as aide de camp to Wayne in his expedition against the Western Indians. He was promoted to a captaincy in 1795, but resigned in 1797 on being appointed secretary of the North-West Territory. In 1799 he was chosen to represent that territory in congress, and after its dissolution in 1801 he became governor of the new territory of Indiana and superintendent of negotiations with the Indians, over whom, on the breaking out of hostilities in 1811, he gained the important victory of Tippecanoe. In 1813 as major general and commander of the north western army he defeated the British forces at the battle of the Thames. In 1814 he concluded a treaty with the North-Western Indians, and in the same year he resigned his commission. He was elected in 1816 member of congress for Cincinnati, in 1819 member of the State senate of Ohio, in 1824 United States senator, and in 1828 minister to Colombia, an office which he held for less than a year, when he retired for a time into private life. By the urgent request of the Whigs he was induced in 1836 to stand for the presidency of the United States, and though unsuccessful, he at the next election in 1840 defeated the same candidate Van Buren by an overwhelming majority, after a canvass memorable for the extraordinary enthusiasm it awakened, and historically important for its introduction of new political methods—many of the most characteristic features of Western elections having then origin in this "Harrison campaign." He was severely stricken, however, to enter upon the discharge of his duties as president, dying April 4, 1841, about a month after his inauguration. Harrison published at Cincinnati in 1838 a small treatise on the Indians entitled *A Discourse on the Aborigines of the Ohio Valley*.

HARROGATE, a town and watering-place in the West Riding of Yorkshire, England, is beautifully situated on a fine plateau near the River Nidd, 18 miles W of York. It is indebted for its rise and importance to its medicinal springs, and is now the principal inland watering-place in the north of England. It consists of two scattered townships, Low Harrogate and High Harrogate, which have gradually been connected by a continuous range of handsome houses and villas. A common of 200 acres, which is secured by act of parliament from ever being built upon, stretches in front of the main line of houses, and on this account Harrogate, notwithstanding its rapid

increase, has retained all its rural charm. As the town is equidistant from the east and west coasts, its air is supposed to possess certain special qualities, and there is the further advantage of a choice between the more bracing atmosphere of High Harrogate and the sheltered and warm climate of the low town. The waters are calcareous, sulphurous, and saline, and some of the springs possess all these qualities to a greater or less extent. The principal chalybeate springs are the Towitt well, called by Dr Dought, who wrote the first account of it, the "English Spa," discovered by Captain William Slingby of Bolton Hall about the year 1570, the Royal Chalybeate Spa, more commonly known as John's Well, discovered in 1631 by Dr Stanhope of York, and provided with a neat octagonal building erected in 1842, Muspiatt's chalybeate or chloride of iron spring discovered in 1819, but first properly analysed by Dr Sheridan Muspiatt in 1867, and the Stanbeck springs midway between High Harrogate and Knaresborough. The principal sulphur springs are the old sulphur well in the centre of Low Harrogate, discovered about the year 1686, the Montpelier springs, the principal well of which was discovered in 1822, situated in the grounds of the Crown Hotel and surmounted by a handsome building in the Chinese style containing pump room, baths, and reading room, and the Harlow Cai springs, situated in a wooded glen about a mile west from Low Harrogate. Nest Harlow Cai is Harlow observatory, a square tower 100 feet in height, standing on elevated ground and commanding a very extensive view. A saline spring situated in Low Harrogate was discovered in 1783. Besides the hotels and churches, the principal public buildings are the High Harrogate college, a boarding school for young gentlemen; the new Victoria baths, erected in 1871 at a cost of £20,000, the Bath hospital for poor patients, founded in 1824, and the Rogers almshouses, founded in 1869. About a mile to the south-east of Harrogate the Cymple valley is spanned by a railway viaduct 1850 feet in length. The population of the town in 1861 was 4737, and in 1871 6843.

HARROW-ON-THE-HILL, a village of Middlesex, England, 10 miles N W of London, derives the latter part of its name from its position on a hill which rises from the surrounding plain to the height of about 200 feet. On the summit, and forming a conspicuous landmark, is the church of St Mary, said to have been founded by Lanfranc, archbishop of Canterbury, in the reign of William I, but of the original building very little is now left. Harrow is chiefly celebrated for its school, founded in 1871 by John Lyon, a yeoman of the neighbouring village of Preston who had yearly during his life set aside 20 marks for the education of poor children of Harrow. Though the charter was granted by Queen Elizabeth in 1571, and the statutes drawn up by the founder in 1590, two years before his death, it was not till 1611 that the first building was opened for scholars. Lyon originally settled about two-thirds of his property on the school, leaving the remainder for the maintenance of the highway between London and Harrow, but in the course of time the values of the respective endowments have changed, and while the road commissioners receive about £3600, the school's share is only about £1600. In 1660 the headmaster, taking advantage of a concession in Lyon's statutes, began to receive "foreigners," i.e., boys from other parishes, who were to pay for their education. From that time the property of the school may be dated. In 1809 the parishioners of Harrow appealed to the Court of Chancery against the manner in which the school was conducted, but the decision, while it recognized their privileges, confirmed the right of admission to foreigners. At present foundationers receive their education at a slightly

cheaper rate than foreigners; there are none who are taught gratis. The government of the school was originally vested in six persons of standing in the parish, who had the power of filling vacancies in their number by election among themselves; but under the Public Schools Act of 1868 the governing body now consists of the surviving members of the old board, besides six new members who are elected respectively by the Lord Chancellor, the universities of Oxford, Cambridge, and London, the Royal Society, and the assistant masters of the school. There is a considerable number of scholarships in connexion with the school to both the great English universities, some to special colleges, others to colleges in the choice of the holders. The general mode of instruction and discipline is modelled on that of Eton, where most of the former headmasters of Harrow were educated. Originally an exclusively classical school, mathematics became in 1837 a compulsory study at Harrow; modern languages, compulsory on the upper forms only since 1851, were extended to the whole school in 1855; while English history and literature began to be more especially studied about 1869. Science, music, and drawing are now also taught. Among the famous men who have been educated here may be mentioned Bruce, the Abyssinian traveller, Sir William Jones, the Orientalist, Dr Parr, who was born at Harrow, Admiral Rodney, Sheridan, Byron, Peel, Theodore Hook, Lord Palmerston, Lord Herbert of Lea, the earl of Shaftesbury, and Archbishop Trench. Comparatively little change was made in the school buildings till 1819, when the new portion was begun; but since that time improvements and additions have steadily increased. In 1839 a school-chapel was consecrated; but this has been gradually replaced by a handsomer edifice completed in 1857. The Vaughan library was built in 1861-63, and a hospital for the boys in 1865. A new speech room, a gymnasium, and laboratories have been erected out of the Lyon Tercentenary Fund, subscribed since 1871. The population of the parish in 1871 was 5537, and of the local board district 4997.

HARRY, BLIND, or HENRY THE MESSENGER, author of a poem in twelve books, entitled *The Acts and Deeds of the Valiant and valiantest champion, Sir William Wallace, Knight of Ilkerton*. All that is known of Henry's personal history is contained in the following quotation from Major:—"Henry, who was blind from his birth, composed in the time of my youth the whole book of William Wallace, and embodied all the traditions about him in the ordinary measure, in which he was well skilled. By the recitation of these in the presence of the great, he procured, as indeed he deserved, food and clothing." Major was born about 1469, and the only MS. copy of Henry's works is that in the Advocates' Library, Edinburgh, dated 1488. It was first printed at Edinburgh in 1670. In his *Lives of Scottish Worthies*, P. F. Tytler claims for it a certain historical worth, as "the work of an ignorant man, who was yet in possession of valuable and authentic materials." On account of its glorification of the national hero it has enjoyed a long popularity among the Scottish peasantry, but it possesses no poetical merit except a certain rude fire and energy, and as a literary production its place must be reckoned a very humble one.

HARTE-BEEST (*Alecephus caama*), a species of antelope, occurring in considerable numbers throughout southern and central Africa. It stands nearly 5 feet high at the shoulders, and is somewhat ungainly in form owing to the disproportionate development of its fore and hind quarters—a difference which gives to the posterior limbs when in motion an appearance of weakness. The head is long and narrow, and is crowned in both sexes by a pair of nearly cylindrical horns, ringed throughout their lower half

and smooth above. The hair of this species is short, soft, and recumbent, and is of a brownish-yellow colour above and nearly white beneath, the colour, however, being to some extent dependent on age and sex and on the season of the year. The harte-beest is gregarious, living in herds of from five to ten individuals, and frequenting tracts of uninhabited wilderness, or the light brush forest in the neighbourhood of rivers. It is exceedingly wary, and consequently difficult of approach, and when suddenly come upon, the entire herd, according to Sir Andrew Smith, scampers off in the train of a leader,—the herd being rarely seen, when in flight, otherwise than in a string, one treading on the footsteps of another. Of a mild and gentle disposition, the harte-beest seeks safety, whenever it can, in flight; when at bay, however, it does not hesitate to turn upon its pursuers and to make use of its powerful horns as weapons of offence. During the heat of the day it is said to rest

Harte-beest.

leaning against the trunks of trees, when the colour of its body so harmonizes with that of the bark as frequently to enable it to elude observation. Dr Schweinfurth, who had frequent opportunity of observing these animals in central Africa, describes a curious and as yet unexplained habit of which he was himself a witness. Having approached nearer to a herd of harte-beests than usual without attracting their attention, he observed them running in couples like the horses in a circus, "going round and round a clump of trees, whilst the others stood in groups of three or four intently watching them. After a time these in turn took their place, and, two at a time, ran their own circuit in a similar fashion." He conjectures that the performance had probably some connexion with pairing time. The flesh of this species is considered superior to that of any other South African antelope, the eland alone excepted.

HARTFORD, a city in the United States of North America, in 41° 45' 50" N. lat. 72° 40' 45" W. long., is the eastern portion of the town of the same name, the county seat of Hartford county, and the capital of the State of Connecticut. It is situated on the west bank of the Connecticut river, 60 miles from Long Island Sound, at the head of steamboat and sloop navigation, and 100 miles N.E. of New York and 95 W.S.W. of Boston by rail. An important centre of railway communication, it has a regular line of steamboats and packets, besides some 200 sailing craft engaged in the coasting trade. The river is usually closed from the middle of December to the

nam, the town-hall, the exchange, in the Gothic style, erected in 1875 at a cost of £10,000, the mechanics institute, and the theatre. A Government school of art was established in 1871. The manufactures of the two towns are very much alike: they possess, now works, puddling furnaces, brass and iron foundries, engine and boiler works, sawmills, cement works, tile works, and breweries. With the addition of the new docks, completed in 1879, the dock area between the towns is 86 acres, besides which there are ponds with an area of about 80 acres. Considerable difficulty has been found in maintaining a sufficient depth of water at the harbour bar of Hartlepool, and although the use of a powerful dredge has been so far effectual, it is probable that the only adequate remedy will be the extension of the breakwaters. A large lighthouse for guiding the entrance of vessels, was erected in 1846-47 at a cost of nearly £6000. In the shipping returns Hartlepool and West Hartlepool are classed together as one port, in 1878 the number of vessels that entered the port, including those in ballast, was 4640, with a tonnage of 885,762, the number that cleared 4602, with a tonnage of 902,370. For the five years ending 1878 the average number of vessels that entered was 5371, with a tonnage of 975,039, while 6417 cleared, with a tonnage of 1,005,710. The principal exports are coal, coke, machines, and cotton, linen and woollen goods, and the principal imports, timber, cattle, corn, provisions, and wool. The fisheries are considerable. The town is much visited in summer for sea-bathing. Several caverns, which may be explored for nearly fifty yards, have been excavated by the sea out of the rocks on the shore of the peninsula. The parliamentary borough of the Hartlepoles has an area of 7287 acres, and besides Hartlepool includes Staunton (in which parish West Hartlepool is situated), Seaton Creek, and Throston. Its population in 1861 was 27,476, and in 1871, 38,203. The population of the municipal borough of Hartlepool in 1861 was 12,218, and in 1871, 13,166, and the population of Staunton in 1861 was 13,601, and in 1871, 23,166.

The name Hartlepool means the pool or lake of Hart. The town grew up round a monastery which had St Hilda as its abbess, and the harbour was of some consequence as early as 1173. In the 14th century Hartlepool belonged to the Bishops of Durham in Scotland, the progenitors of the royal family of that name. The town was erected into a borough about 1200. After Baco ascended the Scottish throne his English possessions were forfeited, and Hartlepool was granted to the monks. It suffered severely from the Scots in 1544, and again in 1558 after the battle of Flodden. During the great northern rebellion in the reign of Elizabeth it was used by the insurgents. In 1644 it was taken by the Scottish army, and its removal in the previous year had laid it in ruins. West Hartlepool was founded in 1844 by Mr R. W. Jackson, the first M.P. for the borough of the Hartlepoles. Its first dock was constructed in 1847, after which it increased with great rapidity.

HARTLEY, DAVID (1705-1757), who may justly be called the founder of the English Association school of psychologists, was born on the 30th August 1705. His father, who was vicar of Ainslie in Yorkshire, wished him to enter the church, and with this view he was sent at the age of fifteen to Jesus College, Cambridge, where he studied under Saunders on the mathematician, and distinguished himself so much that he was elected a fellow of his college. But his university career so far modified his opinions that, feeling himself no longer able conscientiously to sign the Thirty-nine Articles, he abandoned his first intention and devoted himself to the study of medicine. He, however, remained in the communion of the English Church, living on intimate terms with the most distinguished churchmen of his day, among whom may be named Joseph Butler, Warburton, Law, Hoadley, and the poet Young. Indeed he asserted it to be a duty to obey ecclesiastical as well as civil authorities. The doctrine to which he most strongly

objected was that of eternal punishment. His keen interest in theology is proved by the fact that he devoted a large part of his *Observations* to that subject, the objective side of which he treated upon orthodox lines. The life of Hartley was the useful life of a benevolent and studious physician. He practised at Newark, Bury St Edmunds, London, and lastly at Bath, where he died on the 28th August 1757, within two days of his fifty-second birthday. It was at the age of twenty-five that he commenced the series of essays that was to make up his *Observations on Man*, essays that were to subject the mind to the praise of his *Frame, his Duty, and his Expectations*. The praise of originality cannot be denied him. It is noteworthy, however, that very nearly at the same time with the publication of Hartley's *Observations* (1749), two works appeared in French expounding theories essentially similar to his—Condillac's *Traité sur l'Origine des Connoissances humaines* (1746) and the *Parité Analytique de l'Âme* by Charles Bounet of Geneva, whose coincidence with Hartley in the most distinctive features of his philosophy is extremely remarkable. But Hartley's own account of the matter is so straightforward as to command immediate assent. His physical theory, he tells us, was drawn from certain speculations as to nervous action, which Newton had published in his *Principia*. His psychological theory was suggested by an *Essay on the Fundamental Principle of Taste or Morality* (written by a clergyman named Gray, and prefixed by Law to his translation of Archbishop King's Latin work on the *Origin of Evil*), the chief object of which was to show that sympathy and conscience are developments by means of association from the selfish feelings. It is justly to Hartley's credit that he so frankly owned his obligations to a work so far inferior to his own in completeness and tone of thought.

The outlines of Hartley's theory are as follow. With Locke he asserted that the mind is a blank, and is formed by a growth from simple sensations, those states of consciousness which appear most remote from sensation come into being. And the one law of growth of which Hartley took account was the law of contiguity, synchronism and succession. By this law he sought to explain, not only the phenomena of memory, which others had similarly explained before him, but also the phenomena of emotion, of reasoning, and of voluntary and involuntary action.

By his physical theory Hartley gave the first strong impulse to the modern study of the intimate connexion of physiological and psychical facts which is proved so fruitful, though his physical theory in itself is inadequate, and has not been fully adopted. He held that sensation is the issue of a vibration, that the particles of the medullary substance of the nerves, to account for which he pointed, with Newton, a thin elastic ether, rise in the interstices of solid bodies and in those close neighbourhood, and denser as it recedes from them. Pleasant is the issue of small vibrations, pain of vibrations so violent as to break the continuity of the nerves. These vibrations leave behind them in the mind a tendency to further vibrations or "vibrations." This memory is accounted for. The course of reminiscences and of the thoughts generally, when not immediately dependent upon external sensation, is accounted for on the ground that these are always vibrations in the brain on account of its heat and the pulsation of its arteries. What these vibrations shall be is determined by the nature of each man's past experience, and by the influence of the circumstances of the moment, which causes now one new rather tendency to follow than the other. Sensations which are associated together become each associated with the ideas corresponding to the others, and the ideas corresponding to the associated sensations become associated together, sometimes so intimately that they form what appears to be a new simple idea, not without careful analysis resolvable into its component parts.

Starting, like the modern Associationists, from a detailed account of the phenomena of the senses, Hartley tries to show how, by the slow laws, all the emotions, which he analyses with scientific skill, may be explained. Locke's incomplete phrase "association of ideas" is employed throughout, "ideas" being taken as including every mental state but sensation. He emphatically asserts the existence of pure disinterested sentiment, while declaring it to be a growth from the self-regarding feelings. Voluntary action is explained as the result of a firm connexion between a motion and a sensation or "idea," and, on the physical side, between an "ideal" and a motory vibration. Therefore in the Freewill con-

theory Hartley took his place as a Determinist. It is singular that, as he tells us, it was only with reluctance, and when his speculations were nearly complete, that he came to a conclusion on this subject in accordance with his theory.

Hartley's theory of reasoning is forced into agreement with the rest of his system. He declares that "assent and dissent, what we call their pleasure and pain, nature may be, must come under the notion of ideas, being only those very complex internal feelings which adhere by association to such clusters of words as are called propositions. And thus a mathematical proposition is nothing more than a group of ideas united by association," this group of ideas including not only the sum of the ideas belonging to the terms of the proposition, but also those which belong to equality, consequence, and truth."

The remaining half of the *Observations* is devoted to discussion of theological questions, to practical ethics, and does not call for detailed notice. While emphatically asserting his faith in supernatural religion, in the psychological part of his work he treats, not only of conscience, but also the religious emotions entirely as developments from sensation, in the same sense as the pleasures of imagination.

Clarity, freedom from redundancy, and a severe simplicity and brevity are the best characteristics of his style. "No book," writes Sir James Mackintosh, "perhaps exists in which, with so few of the common ailments, comes at last so much to please by the picture it presents of the writer's character. Whoever has read a careful paragraph on the work must be unfortunate if he does not see, feel, and own that the writer was a great philosopher and a good man." (T. M. W.)

HARTLIB, SAMUEL (c. 1600-1669) was born towards the beginning of the 17th century at Elbing in Prussia, his father being a refugee from Poland. His mother was English. About 1628 Hartlib came to England, where he carried on a mercantile agency, and at the same time found leisure to enter with interest into the public questions of the day. An enthusiastic admirer of Comenius, he published in 1637 his *Conatus Comenianus cum Præfatione*, and in 1639 *Comenii Panoptheus Pro Divinis et Dialecticis Dissertationibus*. In 1641 appeared his *Relation of that which hath been lately attempted in poems, poetical, peace among Protestants, and A Discourse of Massey's*, containing his ideas of what a model state should be. During the civil war Hartlib occupied himself with the peaceful study of agriculture, printing at his own expense several treatises by others on the subject. In 1650 he issued the *Discourse of Flanders Husbandry* by Sir Richard Weston, and in 1651 his *Legacy, or an Enlargement of the Discourse of Husbandry used in Brabant and Flanders*, by Robert Child (see *AGRICULTURE*, vol. 1, p. 397). For his various labours Hartlib received from Cromwell a pension of £100, afterwards increased to £300, as he had spent all his fortune on his experiments. He planned a school for the sons of gentlemen, to be conducted on new principles, and this probably was the occasion of his friend Milton's *Treatise on Education*, addressed to him in 1644, and of Sir William Petty's *Two Letters* on the same subject, in 1647 and 1648. His own literary labours were mostly confined to prefaces and short essays. Dylho, a contemporary, says that Ad. Speed, while engaged on his *Improvements in Husbandry*, was lodged and entertained by Samuel Hartlib. At the Restoration Hartlib lost his pension, which had already fallen into arrears, he petitioned parliament for a new grant of it, but what success he met with is unknown, as his latter years and death are wrapped in obscurity. 1662 has been assigned as the probable year of his death, as the latest of his extant letters bears that date.

His other publications are the following:—*Considerations tending to England's Reformation in Church and State*, 1647; *Translation of Mr. John Duns*, 1650; *Tunser's Doubting Conscience Reformed*, 1655; *A true and ready way to learn the Latin Tongue*, 1656; *The Reformed Commonwealth of Israel*, and *The Rightmost Virginian Governor*, 1655, and *The Oriental Expedition*, 1659. See *Biographical Memoirs of Samuel Hartlib*, by H. Drake, 1866; *Comenius's Magistrate*, January 1802; *Watson's Milton*, Harte's *Agicultural Essays*, Donaldson's *Agriculture of Biography*, and *Messers's Milton*.

HARTMANN, MORITZ (1821-1873), a German poet and novelist, was born of Jewish parents at Dachschnik in Bohemia, October 15, 1821. He studied at Prague and Vienna, and after a tour in Italy, Switzerland, and South Germany became a teacher in Vienna. He left Austria, however, in 1844, in order to publish without danger a volume of patriotic poems entitled *Ketich und Salvator*, which appeared at Leipzig in 1845, and in which he gave expression to somewhat radical sentiments as regards both church and state, in language full of the fire of youthful passion and tinged with considerable poetic fancy. After residing for some years in Belgium and France, he came to Leipzig, where in 1847 he published *Neuer Gedichte*. On his venturing towards the close of this year to return to Austria he suffered short imprisonment, from which he was freed by the revolution of the following March. In the same year he was chosen to represent the district of Leutnitz in the Frankfurt parliament, where he took his seat on the extreme left. In October he accompanied Blum and Frobelt to Vienna, but he made his escape before the execution of Blum, and took part in the deliberations of the "Rump Parliament" at Stuttgart. In 1849 he published the *Reinhold oder des Pfaffen Meinungen*, a satirical political poem in the style of the old chronicles. After the dissolution of the "Rump Parliament," he went to Switzerland, then to England and Ireland, and in 1850 to Paris, where, besides other literary engagements, he held that of correspondent to the *Kölnische Zeitung*. On the outbreak of the Russian war he became correspondent of the same paper in the Crimea, where he remained eighteen months. After several years' residence at Paris he settled in 1860 at Ghent, where he delivered courses of lectures on German literature and history in some of the principal academies. In 1863 he removed to Stuttgart to edit the *Freya*, and in 1868 he undertook the editorship at Vienna of the *Neue Presse*. He died at Oberdöbling near Vienna, May 13, 1873. Hartmann published several volumes of poems in addition to those already mentioned, and besides his spirited accounts of his travels and adventures he is the author of various novels of more than average merit. A series of tales (*Novellen*, 3 vols.) appeared in 1863, and a second series (*Nach Natur*, 3 vols.) in 1868. His collected works were published at Stuttgart in 10 vols., 1878-79, and a selection of his poems at the same place in 1871.

HARTMANN VON AUE, a Middle High German poet, was born about 1170. He was of knightly rank, and held a fief at Aue, which was probably on the upper Neckar. He seems to have been educated in a monastery, and was able to read and write. Among his accomplishments was a knowledge of French, and as he took part in the third crusade he must be considered to have passed under the influence which were in his time most favorable to poetic impulse. Although his lyrics are not without merit he excels chiefly in narrative poetry, and the best known of his narrative poems, which were also one of the earliest, is *Der arme Heinrich* ("Poor Henry"). Some of the incidents of this tale are exceedingly repulsive, but others are marked by delicate grace and pathos. Two other tales, *Erce* and *Iwein*, the former written before 1197 and the latter before 1204, treat of the Arthurian legend, and are based upon French poems by Chrétien de Troyes. The story of each is clearly conceived, and the diction is fresh, harmonious, and animated. Hartmann has neither the exquisite finish and charm of Gottfried of Strasburg, nor the soaring imagination of Wolfram von Eschenbach, but he stands next to these supreme medieval writers in the power of giving artistic shape to strong feeling. He is mentioned as alive in 1207 by Gottfried of Strasburg, but in 1220 his death is deplored by Heinrich von dem Türlin in the *Krone*.

Each of his works has found a special editor, and a complete edition of his writings has been issued by E. Bach in the *Bibliotheca (Brevier der Mittelalters)*. See L. Schmidt, *Stand, Mensch, und Geschlecht des Mittelalters*, Harlemons (1871)

HAARTSIORN, SPIRITS, of a name signifying originally the ammoniacal liquor obtained by the distillation of hoim shavings, afterwards applied to the partially purified similar products of the action of heat on nitrogenous animal matters generally, and now popularly used to designate solution of ammonia. See *AMMONIA*, vol. 1 p. 741, and *CHAMBERLAIN*, vol. v p. 509

HARUN ER RASHID See *HAROUN AL RASCHID*
HARUSPICES (initially called observers, of *Sit held*, Gr. *χρηστί*), a class of soothsayers in Rome. Their art consisted especially in deducing from the appearance presented by the entrails of the slain victim the will of the gods. They also interpreted all portents or unusual phenomena of nature, especially thunder and lightning, and prescribed the expiatory ceremonies after such events. To please the god, the victim must be without spot or blemish, and the practice of observing whether the entrails presented any abnormal appearance, and thence deducing the will of heaven, was also very important in Greek religion. This art, however, appears not to have been, as some other modes of ascertaining the will of the gods undoubtedly were, of genuine Aryan growth. It is foreign to the Homeric poems, and must have been introduced into Greece after their composition. In like manner, as the Romans themselves believed, the art was not indigenous in Rome, but derived from Etruria. The *Haruspices* were said to have learned it from a being named Tages, grandson of Jupiter, who had suddenly sprung from the ground near Taurina. The art was practised in Rome chiefly by Etruscans, seldom by native-born Romans who had studied in the priestly schools of Etruria. Though it was of great importance under the early republic, it never became a part of the state religion. In this respect the haruspices ranked lower than the augurs, the latter were a more ancient and purely Roman institution, and were a most important element in the political organization of the city. In later times the art fell into disrepute, and the saying of Cato the censor is well known, that he wondered one haruspex could look another in the face without laughing (*Cic. De Div.*, ii. 24). Under the empire, however, we hear of a regular college of sixty haruspices, and Claudius is said to have tried to restore the art and put it under the control of the pontifices.

HARVARD COLLEGE, the earliest institution of learning in the United States and on the continent of North America. The record gives its origin thus: The English colonists on Massachusetts Bay, settling at what is now Boston in 1630, began a plantation the next year three miles up Charles River, which they called "New Towne." The colony count of September 1636 "agreed to give £400," which exactly doubled the public tax for the year, "towards a school of collidge, whereof £200 to be paid the next year, and £200 when the work is finished, and the next count to appoint whence and what building." In November 1637 "the Collidge is ordered to be at New Towne," the name of which had been changed to Cambridge, and a committee was appointed "to take order" for it. In March 1638-39 "it is ordered that the collidge agreed upon formerly to be built at Cambridge shalbee called Harvard Collidge." The reason was that the Rev. John Harvard, B.A. 1632, and M.A. 1635, of Emmanuel College, Cambridge, England, dying in Charlestown, Massachusetts, September 14, 1638, by will left half his estate, about £800, and his library, to the widelness summary. The college charter of 1650 declared the object to be "the

education of the English and Indian youth of this country in knowledge and godliness." The first brick edifice on the college grounds, having rooms for twenty of the aborigines, was called "the Indian college." In it was printed the apostle Eliot's translation of the Bible into the language of the natives, with primers, grammars, tracts, &c. Several of the natives were members of the college, only one graduated from it. By generous aid received from abroad for this special object, the college was greatly helped in its infancy.

Thus from the beginning private munificence rather than the public treasury fostered and sustained the college, and with steadily increasing preponderance all through its history have its supplies and endowments come from the generosity of individuals. Giants from the colony, province, and State, of small sums for alliances and incidental purposes, made annually or at intervals, wholly ceased more than sixty years ago. With scarce an exception all the present invested funds of the college and of its professional schools, amounting to \$3,615,538 87, with the halls, library, and apparatus, are the benefactions of its friends.

The charter constitutes as a corporation a president, treasurer, and five fellows, who initiate all measures concerning the college, hold its funds, and have the nomination for filling vacancies in their own body, as also of all the officers for instruction and for the internal government of the institution in all its departments, subject, however, to the advice and approval and final action of a board of overseers. The State, claiming as founder and patron, till quite recently regarded the college as a State institution, over which it should exercise a direct control through the legislature and the executive, by its authority in the membership and the election of the whole or a part of the board of overseers. Various modifications made from time to time in the composition or method of choice of the members of this board not relieving the controversies and embarrasments incident to legislative action, which proved prejudicial to the best interests of the college, its organic connexion with the State by this was severed by statute in 1866. The board of overseers as now constituted is composed of thirty of the alumni, besides the president and the treasurer, elected by the ballots of the alumni on commencement day at the college, in sections of five, serving a term of six years. With its complement of professional schools of law, medicine, theology, science, and many special departments of the latter, more than any other institution in America, and with but a few gaps yet to be filled in its completeness of method and equipment to bring it to comparison with foreign institutions of learning, Harvard College may claim to be in the most comprehensive sense of the term a university, a title which is, indeed, assumed, and generally applied to it. Recent changes in the course of study in the college have allowed a wide range for elective studies to undergraduates, the proportions being, one-fourth obligatory, three-fourths elective. In the professional schools most of the studies are obligatory. The number of bound volumes in the library and schools is 232,200. The number of halls owned and occupied for college uses is twenty-nine of brick or stone, including ten for students' chambers. The whole number of professors, instructors, &c., in all departments, is 135, of librarians, proctors, and other officers in the service of the college, 23. The number of the alumni of the college proper about 9600, the number in all departments about 14,000.

HARVEST-BUG, a name erroneously applied to the hexaped larval condition of a mite, not one of the *Insecta*, but belonging to the division *Acaridea* of the class *Arachnida*. It is very small, of a brick-red colour, and swarms both among wild vegetation and cultivated plants, espec-

ally near the sea, attaching itself, however, on the first opportunity to the bodies of human beings, hairs, dogs, cats, and other mammals, and even insects. On touching the skin, it rapidly burrows deeply into it, causing a painful itching, followed by a swelling of irritation and severe itching with the individuals attacked, and enduring for several days. It is usually at the end of July or in August that these mites make their appearance, and the frequency with which they attach themselves to the lower extremities of people walking in fields at harvest time has given rise to their trivial name. The effect of their subcutaneous presence varies in different people, as above mentioned, in some it assumes so irritating painful an aspect as to originate a disease called autumnal erythema. Such severity of symptoms is generally found in warmer climates than that of Great Britain, the mite however is plentiful, and causes much annoyance, in Scotland. Extraction with a fine needle, under a magnifying power, is the best way to get rid of the pests, but the application of a solution of carbolic acid, benzine, sulphur ointment, or any other powerful and easily diffused insecticide agent will usually soon destroy them.

The scientific name of this creature is *Lepus* (*Lepus* or *Tetranyx* does not) and, in France it has received a very common name, that of "rouget" being the best known. It has been placed in different genera by modern authors, who have hitherto considered it as a fully developed form, of somewhat doubtful affinities. The old naturalists began to suspect its correct status as an imperfect *Acaris*, but it has been reserved for the French naturalist, M. P. Magnan, to prove from actual observation the fact that it is only the larva of a well known mite, *Trombidium holosericeum*. As a bright small species often found in spring and early summer in gardens and fields. This distinguished biologist has in his manner put beyond doubt the identity of various other members of the *Acaridae*, hitherto disconnected. In April he found both sexes of the perfect mite, but at the end of May and in June only gravid females occurred. These in June and July deposited their eggs, from which was hatched the creature hitherto known as *Acarus* (*Lepus*) *aculeatus*. As a result this has implanted its mandibles into the skin of the individual attacked, its abdomen dilates perceptibly, finally becoming about five times as large as on leaving the egg, though the cephalothorax and limbs remain unchanged. It hibernates in an ootheca, or pupa, and after hibernation, during which the nutritive fluids imbedded in the preadult stage are assimilated, the adult stage of a purely phytophagous *Trombidium*, capable of reproduction, is revealed.

There seems every reason to believe that the skin irritation caused in Mexico by a supposed insect, called *Thalassius* or *Thalassius* *hirsutus* by the Indians, is really produced by this or a closely allied mite. Similar complaints are frequently caused by mites in Bituri, Martineque, Honduras, &c., and the symptoms are naturally aggravated in such tropical localities.

As a result, with figures, of all the stages of *Trombidium holosericeum* and the allied *T. fulgidum* (of which the octopod *T. phalangis*, parasitic upon very long-legged spiders, is the nymph or pupa) will be found in the *Annales des Sciences Naturelles*, June 1866, in (1876).

HARVEY, GABRIEL (1846–1890), an English writer of the Elizabethan period, was the eldest son of a rope maker at Saffron Walden, and received his education at Christ's College and Pembroke Hall, Cambridge, where we find him about 1576–78 lecturing on rhetoric. Immediately afterwards he appears to have been sent abroad by his patron the earl of Leicester, to whom he refers in his *Gratulationum Waldensium libri quatuor* (Lond., 1578), a collection of pieces in honour of the queen's visit to Audley End, near his native town. In 1585 he became doctor of laws. Though Harvey expresses a desire to be "epitaphed the inventor of the English Iliocretter," his name, familiar enough to his more learned contemporaries, would probably have been well nigh forgotten had it not been for his friendship with Spenser and his hostilities with Greene and Nash. To the student of Spenser he is familiar as one of the poet's principal correspondents, and as the Hobbinol who wrote the poem prefixed to the "Faerie Queene." His quarrel with Greene and Nash was begun by Greene allud-

ing in his *Quip for an Upstart Courtier* (1592) to the fact that Harvey was the son of a rope maker, and after Greene's death it raged with even increasing violence until the archbishop of Canterbury issued an order for the seizure of all works written by either of the combatants.

HARVEY's extant publications, which contain many more matters of interest to the student of literature, are—*Quercus*, London, 1577; *Revelation*, *vel chronica de non Oritus de Nativitate*, 1578; *De Revolutionibus*, 1577; *Amoribus ad Amorem*, 1578; *Amoribus*, 1578, in honour of the scholar Sir Thomas Smith, *Poetae Latini et Graeci*, 1578, especially touching Robert Greene and other poets by him named, 1578; *Super Gregorio*, on a new *Prophetia* of the *Old Testament*, 1578, but unexecuted; by Mr Collier, 1608, *A new Letter of Notable Contents*, 1598; *The Trimming of Thomas Nash, Gentleman*, by the highly titled Don *Alonso de Mendoza*, 1597, inserted in *The Book of Colchester's Abbeys*, Lond., 1871; *Sir Walter's History of English Poetry*, Hazlitt's edition, and J. P. Collier's *Bibliographical and Critical Account of the Lives of Poets in the English Language*, Lond., 1866, under "Harvey," "Nash," and "Greene."

HARVEY, SIR GEORGE (1808–1876), a Scottish painter and president of the Royal Scottish Academy, was the son of a watchmaker, and was born at St Ninians, near Stirling, in February 1806. Soon after his birth his parents removed to Stirling, where George was apprenticed to a bookseller. His love for art having, however, become very decided, he in his eighteenth year entered the Trustees' Academy at Edinburgh. Here he so distinguished himself that in 1826 he was invited by the Scottish artists, who had resolved to found a Scottish academy, to join it as an associate. Indeed it was chiefly to the zeal and judgment of Harvey and of two others that owed its early success Harvey's first picture, *Valley School*, was exhibited in 1826 at the Edinburgh Institution, and from the time of the opening of the Academy in the following year he continued annually to enrich its exhibitions by a succession of pictures which, although they never obtained much fame beyond the limits of Scotland, appealed with such effect to Scottish sentiment as to win for him in his native land an unrivalled popularity. His best known pictures are those depicting historical episodes in religious history from a puritan or evangelical point of view, such as *Covenanters Preaching*, *Covenanters' Communion*, *John Bunyan and his Blind Daughter*, *Sabbath Evening*, and the *Quitting of the Manse*. He was, however, equally successful in subjects not directly religious, and The Bowlers, A Highland Funeral, The Curriers, A School Strain, and Children Blowing Bubbles in the Churchyard of Greyfriars, Edinburgh, manifest the same close observation of character, artistic conception, and conscientious elaboration of details. In *The Night Mail* and *Dawn Revealing the New World* to Columbus the aspects of nature are made use of in different ways, but with equal happiness, to lend impressiveness and solemnity to human concerns. It was chiefly in his later years that he devoted his attention to landscape, the branch of art in which on the whole he was most successful, and there perhaps in suggesting the deep calm and the sweet and varied charm which broods among the hills when nature is at rest. He also devoted some attention to portraiture, among his works in this branch of art being a portrait of Professor Wilson, now at the Philosophical Institution, Edinburgh. In 1829 he was elected a fellow of the Royal Scottish Academy, and in 1864 he succeeded Sir J. W. Gordon as president. He received the honour of knighthood in 1867. His death took place at Edinburgh, January 22, 1876.

Sir George Harvey was the author of a paper on the "Colour of the Atmosphere," read before the Edinburgh Royal Society, and afterwards published with illustrations in *Good Words*, and in 1870 he published a small volume entitled *Notes of the Forty Years of the Royal Scottish Academy*. *Selections from the Works of Sir George Harvey, F.R.S.A.*, described by the Rev. A. L. Sampson, F.R.S.E., and photographed by Thomas Agnew, appeared at Edinburgh in 1869.

HARVEY, WILLIAM (1578-1657), the discoverer of the circulation of the blood, was the eldest son of Thomas Harvey, a prosperous Kentish yeoman, and was born at Folkestone on April 1, 1578. After passing through the grammar school of Canterbury, on the 31st of May 1593, having just entered his sixteenth year, he became a pensioner of Corpus College, Cambridge, at nineteen he took his B.A. degree, and soon after, having chosen the profession of medicine, he went to study at Padua under Fabricius and Caserius (see *ANATOMY*, vol. 1 pp. 809, 810). At the age of twenty-four Harvey became doctor of medicine, April 1602. Returning to England in the first year of James I., he settled in London, and some years later he married the daughter of Dr. Lanclot Down, who had been physician to Queen Elizabeth. In the same year Harvey became a candidate of the Royal College of Physicians, and was duly admitted a fellow (June 1607). In 1609 he obtained the reversion of the post of physician to St Bartholomew's Hospital. His application was supported by the king himself and by Dr Atkins, the president of the college. On the death of Dr Wilkinson in the course of the same year he succeeded to the post. He was thence censor of the college, and in 1615 was appointed Lecturer in anatomy. In the following year—the year of Shakespeare's death—he began his course of lectures, and first brought forward his views upon the movements of the heart and blood.¹ Meantime his practice increased, and he had the lord chancellor, Francis Bacon, and the earl of Arundel among his patients. In 1618 he was appointed physician extraordinary to James I., and on the next vacancy physician in ordinary to his successor. In 1623, the year of the publication of the *Exercitatio Anatomica de Motu Cordis et Sanguinis*, he was elected treasurer of the College of Physicians, but at the end of the following year he resigned the office, in order, by command of Charles I., to accompany the young duke of Lennox (James Stuart, afterwards duke of Richmond) on his travels. He appears to have visited Italy, and returned in 1632. From that date he accompanied the earl of Arundel on his embassy to the emperor. He was eager in collecting objects of natural history, sometimes causing the earl anxiety for his safety by his excursions in a country infested by robbers after the Thirty Years' War. In a letter written on this journey, he says—"By the way we could scarce see a dog, crow, kite, raven, or any bird, or anything to anatomize, only some few miserable people, the reliques of the war and the plague, whom famine had made anatomies before I came." Having returned to his practice in London at the close of the year 1636, he accompanied Charles I. in one of his journeys to Scotland (1639 or 1641). While at Edinburgh he visited the Baw Rock, he minutely describes its abundant population of sea-fowl in his treatise *De Generatione*, and incidentally speaks of the then credited account of the solar goose growing on trees as a fable. He was in attendance on the king at the battle of Edgehill (October 1642), where he withdrew under a hedge with the prince of Wales and the duke of York (then boys of twelve and ten years old), "and I took out of my pocket a book and read. But he did not read very long before a bullet of a great gun grazed on the ground near him, which made him remove his station," as he afterwards told Aubrey. After the indecisive battle, Harvey followed Charles I. to Oxford, "while," writes the same gossiping narrator, "I first saw him, but was then too young to be acquainted with so great a doctor. I remember he came several times to our college (Trinity) to George Bathurst, B.D., who had a hen

to hatch eggs in his chamber, which they opened daily to see the progress and way of generation." In Oxford he remained three years, and there was some chance of his being superseded in his office at St Bartholomew's Hospital, "because he hath withdrawn himself from his charge, and is retired to the party in arms against the Parliament." It was no doubt at this time that his lodgings at Whitehall were searched, and not only the furniture seized but also invaluable manuscripts and anatomical preparations.²

While with the king at Oxford he was made warden of Merton College, but a year later, in 1647, that city surrendered to Fairfax and Harvey returned to London. He was now sixty-eight years old, and, having resigned his appointments and relinquished the cares of practice, lived in learned retirement with one or other of his brothers. It was in his brother Daniel's house at Combe that Dr (afterwards Sir George) Ent, a faithful friend and disciple (1604-1689), visited him in 1650. "I found him," he says, "with a cheerful and sprightly countenance investigating, like Democritus, the nature of things. Asking if all were well with him—"How can that be," he replied, "when the state is so agitated with storms and I myself am yet in the open sea?" And indeed, was not my mind solaced by my studies and the resolution of the objections I have formerly made, that nothing which should make me desist of a longer continuance. But thus employed, this obscure life and vacation from public cares which would disgust other minds is the medicine of mine." The work on which he had been chiefly engaged at Oxford, and in deed since the publication of his treatise on the circulation in 1628, was an investigation into the circulation but deeply interesting subject of generation. Charles I. had been an enlightened patron of Harvey's studies, had put the royal deer parks at Windsor and Hampton Court at his disposal, and had watched his demonstration of the growth of the chick with no less interest than the movements of the living heart. Harvey had now collected a large number of observations, though he would probably have delayed their publication. But Ent succeeded in obtaining the manuscripts, with authority to print them or not as he should find them. "I went from him," he says, "like another Jason in possession of the golden fleece, and when I came home and perused the pieces singly, I was amazed that so vast a treasure should have been so long hidden." The result was the publication of the *Exercitationes de Generatione* (1651).

This was the last of Harvey's labours. He had now reached his seventy-third year. His theory of the circulation had been opposed and defended, and was now generally accepted by the most eminent anatomists both at home and abroad. He was known and honoured throughout Europe, and his own college erected a statue in his honour (1652), "viro monumentis suis immortal." In 1654 he was elected to the highest post in his profession, that of president of the college, but the following day he is not assembled fellows, and, declaiming the honour for himself on account of the infirmities of age, recommended the re-election of the late president Dr Prinsep. He accepted,

"Innocent mihi prius animus, et summi namque ingenii memos, levem gentium effudit. Dolens mihi hinc causa est eam, inter impiorum nocentes humilis et bella pluvium civile, sed ensuamum regem (idque non solum acutus persequens sed et pium) sequi, i spaces quidam manus non modo edum meum appellationem omnem expleant, sed etiam, que mihi causa gravem quoniamque, adversum meum, multum amorem laboribus parit, e mance meo summi est. Quo factum est ut obscurum plurimum, presertim de generatione in seculum, cum repulchre litam cum (nuncu dicit) d'Almireno, perierit."

—De Gen. et Br. lxxviii To this less Cowley replies—

"O creed was I who can't give thee this!"

Friend and foe may the agent be

And ten times easier 'tis

To Rebut Paul's than any work of his "

¹ A venerable MS notebook in Harvey's own cobbled handwriting was discovered only lately in the British Museum, with the title "Prælectiones anatomicae." &c., this so far as it has been deciphered, contains the germs of his great discovery.

however, the office of consiliarius, which he again held in the two following years. He had already enriched the college with other gifts besides the honour of his name. He had raised for them "a noble building of Roman architecture (justo work with Corinthian pilasters), comprising a great parlour or conversation room below and a library above", he had furnished the library with books, and filled the museum with "samples and rarities," as well as with specimens of instruments used in the surgical and obstetric branches of medicine. At last he determined to give to his beloved college his paternal estate at Burmarsh in Kent. His wife had died some years before, his brothers were wealthy men, and he was childless, so that he was defrauding no heir when, in July 1656, he made the bequest of this property, then valued at £56 per annum, with provision for a salary to the college librarian and for the endowment of an annual oration, which is still given on the anniversary of the day. The orator, so Harvey orders in his deed of gift, is to exhort the fellows of the college "to search out and study the secrets of nature by way of experiment, and also for the honour of the profession to continue mutual love and affection among themselves."

Harvey, like his contemporary and great successor Sydenham, was long afflicted with gout, but he preserved his activity of mind to an advanced age. In his eightieth year, on the 31 of June 1667,¹ he was attacked by paralysis, and though deprived of speech was able to send for his nephews and distribute his watch, ring, and other personal trinkets among them. He died the same evening, "the paley giving him an easy passage," and was buried with great honour in his brother Eliab's vault at Hempstead in Essex, "anno domini famae salutis."

Ambrey, to whom we owe most of the minor particulars about Harvey which have been preserved, says—"In person he was not tall, but of the lower stature, round faced, olivaceous complexion, little eyes, round, very black, full of spits, his hair black as a raven, but quite white twenty years before he died." The best portrait of him extant is by Cornelius Jansen in the library of the College of Physicians, one of those rescued from the great fire, which destroyed their original hall in 1686. It has been often engraved, and is prefixed to the fine edition of his works published in 1766.

Harvey's Work on the Circulation.—In estimating the character and value of the discovery announced in the *Exercitatio de Motu Cordis et Sanguinis*, it is necessary to bear in mind the previous state of knowledge on the subject. Aristotle taught that in man and the higher animals the blood was elaborated from the food in the liver, thence carried to the heart, and sent by it through the veins over the body. His successors of the Alexandrian school of medicine, Erasistratus and Herophilus, further elaborated his system, and taught that, while the veins carried blood from the heart to the members, the arteries carried a subtle kind of air or spirit. But the practical physician only two changes had been made in this theory of the circulation between the Christian era and the 16th century. Galen had discovered that the arteries were not, as their name implies, merely air-pipes, but that they contained blood as well as vital air or spirit. And it had been gradually ascertained that the nerves (*νεῖρον*) which arose from the brain and conveyed "animal spirits" to the body were different from the tendons or sinews (*ψεύρον*) which attach muscles to bones. First, then, the physicians of the time of Linnaeus knew that the blood is not stagnant in the body. So did Shakespeare and Homer, and every ageur

who inspected the entrails of a victim, and every village barber who bled a vein. Plato even uses the expression τὸ αἷμα κατὰ πόρτα τὸ μέγα σφοδρὸς περιεφερόμεν. But no one had a conception of a continuous stream returning to its source (a circulation in the true sense of the word) either in the system or in the lungs. If they used the word *circulatio*, as did Celsus, it was as vaguely as the French policeman cries "Circulez." The movements of the blood were in fact thought to be slow and irregular in direction as well as in speed, like the "circulation" of air in a house, or the circulation of a crowd in the streets of a city. Secondly, they supposed that one kind of blood flowed from the liver to the right ventricle of the heart, and thence to the lungs and the general system by the veins, and that another kind flowed from the left ventricle to the lungs and general system by the arteries. Thirdly, they supposed that the septum of the heart was pervious and allowed blood to pass directly from the right to the left side. Fourthly, they had no conception of the functions of the heart as the motor power of the movement of the blood. They doubted whether its substance was muscular, they supposed its pulsation to be due to expansion of the spirits it contained, they believed the only dynamic effect which it had on the blood to be making it in during its active diastole, and they supposed the chief use of its constant movements to be the due mixture of blood and spirits.

Of the great anatomists of the 16th century, Sylvius (*In Hypo et Gal Phys Postem Anatom. Isagoge*) described the valves of the veins. Vesalius (*De Humani Corporis Fabrica*, 1542) ascertained that the septum between the right and left ventricles is complete, though he could not bring himself to deny the invincible poise which Galen's system demanded. Serretus, in his *Christianae Receptata* (1553), goes somewhat further than his fellow-student Vesalius, and says—"Puriss ille medius non est aptus ad communicationem et elaborationem illam, licet aliquid recedat possit," and, from this anatomical fact and the large size of the pulmonary arteries he concludes that there is a communication in the lungs by which blood passes from the pulmonary artery to the pulmonary vein—"Eodem artificio quo in hepato fit transire una vena potest ad venam cavam propter sanguinem, fit etiam in pulmone transire una vena arteriosa ad alteram venosam propter spiritum." The nature of the spirit of the left side and the vital spirit of the right side of the heart were therefore, he concluded, practically the same, and hence two instead of three distinct spirits should be admitted. It seems doubtful whether even Serretus rightly conceived of the entire mass of the blood passing through the pulmonary artery and the lungs. The transference of the *spiritus naturalis* to the lungs, and its return to the left ventricle as *spiritus vitalis*, was the function which he regarded as important. Indeed a true conception of the lesser circulation as a transference of the whole blood of the right side to the left was impossible until the corresponding transference in the greater or systemic circulation was discovered. Serretus, however, was the true predecessor of Harvey in physiology, and his claims to that honour are perfectly authentic and universally admitted.²

The way then to Harvey's great work had been paved by the discovery of the valves in the veins, and by that of the lesser circulation,—the former due to Sylvius and Fabricius, the latter to Serretus,—but the significance of the

¹ Indeed the same word, *νεῖρον* *αἰσθητικόν*, occurs in the Hippocratic writings, and was held by Van der Linder and others to be the fibres of medicine himself, and not to Columbus or Cassalpianus, belonged the hearts of Harvey.

² Besides Columbus (*De Re Anatomica*, 1556) formally denies the nature of the blood of the heart, yet occurs in the same sense, and is quite pos from the right to the left ventricle, not through the septum,

³ This is the date usually given according to the college annals. Gualtero's *Biogr. apud Hist. of England* makes it June 30, Harvey's constant post. 17, June 15 while Dr Lawrence, following the inscription on the tomb, gives June 3, 1658.

alves was unsuspected, and the fact of even the pulmonary circulation was not generally admitted in its full meaning.

In his treatise Harvey proves (1) that it is the contraction, not the dilatation, of the heart which commences with the pulse, and that the ventricles are true muscular vesicles squeezing the blood which they contain into the aorta and pulmonary artery, (2) that the pulse is not produced by the uterine, enlarging and so filling, but by the arteries being filled with blood and so enlarging, (3) that there are no pores in the septum of the heart, so that the whole blood in the right ventricle is sent to the lungs and round by the pulmonary artery to the left ventricle, and also that the whole blood in the left ventricle is again sent into the arteries, round by the smaller veins into the venæ cavae, and by them to the right ventricle again—thus making a complete "circulation", (4) that the blood in the arteries and that in the veins is the same blood, (5) that the action of the right and left sides of the heart, auricles, ventricles, and valves, is the same, the mechanism in both being for reception and propulsion of liquid and not of air, since the blood on the right side, though mixed with air, is still blood, (6) that the blood sent through the arteries to the tissues is not all used, but that most of it runs through into the veins, (7) that there is no net and no undulation in the veins, but a constant stream from the distant parts towards the heart, (8) that the dynamical starting-point of the blood is the heart and not the liver.

The method by which Harvey arrived at his complete and almost faultless solution of the most fundamental and difficult problem in physiology has been often discussed, and is well worthy of attention. He begins his treatise by pointing out the many inconsistencies and defects in the Galenic theory, quoting the writings of Galen himself, of Fabricius, Columbus, and others, with great respect, but with unflinching criticism. For, in his own noble language, "non enim minus laudem anatomici, nec in doctrina philosophi, quam in fabrica naturæ habere, nec in verbi judicio antiquitatis magistri, et veritatem omnino in apertis relinquunt, et in conspectu omnium deservant." He had, as we know, not only furnished himself with all the knowledge that books and the instructions of the best

but through the Latin, "quod non habemus aut immutavit ut scriptum legitur." The fact that Harvey quotes Columbus and not Servetus is explained by the almost entire destruction of the writings of the latter, which are now among the rarest curiosities. The great anatomist Fabricius, who Harvey described the valves of the veins more perfectly than had Sylvius, Remus, in his lecture on the *Anatomy and Diseases of the Horse* (1600), taught that the left ventricle sent blood and vital spirit to all parts of the body except the lungs—the ordinary Galenic doctrine. Yet on the strength of this phrase Professor Theodorus has actually put up a tablet in the veterinary school at Bologna to Remus as the discoverer of the circulation of the blood! The claims of Cœlius, a more plausible claimant to Harvey's honors, are equally better founded. In his *Questiones Peripneuticæ* (1571) he followed Servetus and Columbus in declaring that we now know as the pulmonary "circulation" under that name, and this is the only sound hint for the invention (first made in Byrlin's treatise) that Cœlius knew "the circulation of the blood." It is even behind Servetus, for he only allows part of the blood of the right ventricle to go round by the "current", some, he conceives, passes through the hypothetical pores in the septum, and the rest is sent out to the lungs and umb, by the inferior vena cava, to the body—"Hanc esse vena cava munit ut omnes partes corporis sanguinem per arterias distribuatur." *Ex dextro ventriculo cordis venæ arterie vena cava superior, inferior et vena cava inferior, arterie vena cava inferior, sanguinem temperatissimum et sanissimum habentem, gradatim sentit.* Cœlius seems to have had no original views on his subject, all that he writes is copied from Galen or from Servetus except some enormous observations of his own. His greatest merit was in a boldness, and no claim to the "discovery of the circulation" was made by him or by his contemporaries. When it was made, Haller decided conclusively against it. The fact that an inscription was lately placed on the bust of Cœlius in a Rome, which states that he was the first to demonstrate and demonstrate "the general circulation of the blood," is only a proof of the blindness of unprepared rational vanity.

antonomies of Italy could give, but, by a long series of dissections, had gained a far more complete knowledge of the comparative anatomy of the heart and vessels than any contemporary—we may almost say than any successor, until the times of Hunter and Meckel. Thus equipped, he tells us that he began his investigations into the movements of the heart and blood by looking at them—*scilicet*, by seeing their action in living animals. After a modest preface, he begins his first chapter "Ex vivorum dissectione, qualis sit cordis motus." He minutely describes what he saw and handled in dogs, pigs, serpents, frogs, and fishes, and even in snails, oysters, lobsters, and insects, in the pulmonary artery, *arteria apollinis*, "quæ Anglice dicitur a *thymus*," and lastly in the chick, while still in the shell. In these investigations he used a *perispermum* or simple lens. He particularly describes his observations and experiments on the ventricles, the auricles, the arteries, and the veins. He shows how the arrangement of the vessels in the fetus supports his theory. He adduces facts observed in disease as well as in health to prove the rapidity of the circulation. He explains how the mechanism of the valves in the veins is adapted, not, as Fabricius believed, to moderate the flow of blood from the heart, but to favour the flow to the heart. He estimates the capacity of each ventricle, and reckons the rate at which the whole mass of blood passes through it. He elaborately and clearly demonstrates the effect of obstruction of the blood stream in arteries or in veins, by the forceps in the case of a snake, by a ligature on the arm of a man, and illustrates his argument by figures. He then sums up his conclusion thus—"Circulatio quodam motu, in circuitu, agitari in animalibus sanguinem, et esse in perpetuo motu, et hanc esse actionem sine functione cordis quam pulsu peragat, et omnino motu et pulsu cordis causam unam esse." Lastly, in the 16th, 16th, and 17th chapters, he adds certain confirmatory evidence, as the effect of position on the circulation, the absorption of animal poisons and of medicines applied externally, the muscular striae of the heart and the necessary working of its valves. The whole treatise, which occupies only 67 pages of large print in the quarto edition of 1766, is a model of accurate observation, patient accumulation of facts, ingenious experiment, bold yet cautious hypothesis, and logical deduction.

In one point only was the demonstration of the circulation incomplete. Harvey could not discover the capillary channels by which the blood passes from the arteries to the veins. This gap in the circulation was supplied several years later by the great anatomist Malpighi, who in 1661 saw in the lungs of a frog, by the newly invented microscope, how the blood passes from the one set of vessels to the other. Harvey saw all that could be seen by the unaided eye in his observations on living animals, Malpighi, four years after Harvey's death, by another observation on a living animal, completed the splendid chain of evidence. If this detracts from Harvey's merit it leaves Servetus no merit at all. But in fact the existence of the channels first seen by Malpighi was as clearly pointed to by Harvey's reasoning as the existence of Neptune by the calculations of Le Verrier and of Adams.

Harvey himself and all his contemporaries were well aware of the novelty and importance of his theory. He says in the adumbrated letter to Dr Argent, president of the College of Physicians, which follows the dedication of his treatise to Charles I., that he should not have ventured to publish "a book which alone asserts that the blood pursues its course and flows back again by a new path, contrary to the received doctrine taught so many ages by so many learned and illustrious men." If he had not set forth his theory for more than nine years in his college lectures, gradually brought it to perfection, and convinced his colleagues by actual demonstrations of the truth of what he advanced. He withstood opposition, and even obloquy, for, from the novelty of his views. These anticipations, however, the great proof to

mia in which the several pteps appear in the chick. He states that the *pinetum salivum* or foetal heit is the first organ to be seen, and explains that the nutrition of the chick is not only effected by yolk conveyed directly into the yolk-sac, as Aristotle thought, but also by absorption from yolk and vitellus by the umbilical (omphalomesenteric) vein, on the fourth day of incubation appear two mases (which he oddly names *se mantes*), one of which develops into three vessels, to form the cranium, cerebellum, and eye, the other into the heart, lungs, and thus, on the sixth or seventh day come the viscera, and lastly, the kidneys and other external parts. Harvey points out how early this mode of development in the chick agrees with what he had observed in mammalia and especially in human embryo. He notes the presence of the foetal heit in man and the equal thickness of the ventricles, the soft cartilages which represent the future bones, the large amount of liquor amnii and liquor of plants which he states the fetus in the third month, in the fourth the position of the uterus in the abdomen, and the uterus with its folds in tubes resembling the uterine bicornis of the sheep, the large thyms, the enormous small vs. in the adult, not forming a second stomach vs. in the pig, the liver, and the lobulated kidney, like those of the wal ("*utidus*," *sc. marnus*) and porpoise, and the large suprarenal vesic, not much smaller than those of the kidney (Ch. vi.). He failed, however, to trace the conversion of the mantes with the kidneys. In the following chapters (Ch. vii. to xviii.) he discusses the process of generation in the fow, deer, &c. &c. After again insisting that all animals rise from ova, that a "conceptus" is an internal egg and an egg is extended as a mass, he goes on to describe the tissues of the ovum, the process of impregnation, and the subsequent development of the fetus and its membrans, the *pinetum salivum*, the cotyledons of the placenta, and the "uterine milk," to which Professor Turner has lately in ideal attention. He concludes with detached notes on the placenta, parturition, and illud salubre.

Harvey's other Writings and Medical Practice.—The remaining writings of Harvey which are extant are unimportant. A complete list of them will be found below, together with the titles of those which we know to be lost.* Of these the most important was probably that on inspiration, and the records of post-mortem examinations. From the following passage (*De Partu*, p. 550) it seems that he had a notion of inspiration being connected rather with the production of animal heat than, as then generally supposed, with the cooling of the blood. "Hæc qui diligenter, perpendit, minimoque aere diligeret insuperavit, facile opinor fatiabit eundem nec refrigerationis gratia, nec in pabulum animalibus concedi. Hæc autem obiter duntaxat de respiratione diximus, proprio loco de eadem fortitan copiosius discipulamur."

Of Harvey as a practicing physician we know very little. Aubrey tells us that "he paid his visits on horse back with a footstool, his man following on foot, as the fashion then was." He adds—"Though all of his profession would allow him to be an excellent anatomist, I never heard any that admired his therapeutic way. I knew several practitioners that would not have given the thanks for one of his bills." The apothecaries used to collect physicians' prescriptions and sell or publish them to their own profit, "and that a man could hardly tell by his bill what he did aim at." However this may have been,—and rational therapeutics was impossible when the foundation stone of physiology had only just been laid,—we know that Harvey was an active practitioner, performing such important surgical operations as the removal of a breast, and he turned his obstetric experience to account in his book on generation. Some good practical precepts as to the conduct of labour are quoted by Willoughby, a contemporary. He also took notes of the anatomy of disease, these Harvey was unfortunately perished with his other manuscripts. Otherwise we might regard him as a forerunner of Morgagni, for Harvey saw that pathology is but a branch of physiology, and like it must depend first on accurate anatomy. He speaks strongly to this purpose in his first epistle to Bionatus: "Scit enim sanctorum boni habitus corporum dissectio plurimum ad philosophum et rectam physiologiam facit, is corporum morborum et cachecticorum inspectio potissimum ad patho-

logiam philosophicam." The only specimen we have of his observations in morbid anatomy is his account of the post-mortem examination made by order of the king on the body of the famous Thomas Parr, who died in 1655, at the reputed age of 152. Harvey insists on the value of physiological truths for their own sake, independently of their immediate utility, but he himself gives us an interesting example of the practical application of his theory of the circulation in the cure of a large tumour by tying the arteries which supplied it with blood (*De Genet. et Educ. xix*).

The following is taken out of a complete list of all the known writings of Harvey, published and unpublished—

Exercitationes Anatomicae de Motu Cordis et Sanguinis, 4to, Frankfurt on the Main, 1628; *Exercitationes duæ Anatomicae de Circulatione Sanguinis*, ed. Johanneum Bodanum, Altorf, P. Gessner, Cambridge, 1648; *Exercitationes de Generatione Animalium, quibus occidit quadam de Partu, de Membris ac Functionibus Uteri, et de Conceptione*, 4to, Lond., 1651; *Anatomica Thomas Parr*, first published in the testament of Dr. John Butts, *De Ovis et Nutura Sanguinis*, 8vo, Lond., 1660; *Lectures*—(1) to Christ. Hoffmann of Nuremberg, May 1636, (2) to Sigheg of Hamburg, April 1651, (3) those to Giovanni North of Florence, July 1651, Dec. 1656, and Nov. 1656, (4) two to Dr. Hofmann of Pavia, May 1652, (5) two to Dr. Hens of Darnstadt, Feb. 1654-5 and July 1655, (6) to Dr. Vlackel of Frankfurt, May 1657. His letters to Hoffmann and Vlackel are on the evolution, those to Hofmann, Hens, and Vlackel refer to the discovery of the pulse, the first of Harvey's letters of friendship. All these letters were published by Sir George Bart in his collected works (Leyden, 1827). Of two MS. letters, one on official business to the secretary Donchastel was printed by Dr. A. Leining, with a facsimile of the cursive handwriting of Harvey, 1775, and the other, about a patient, appears in Dr. Willis's *Life of Harvey*, 1778. *Praelectiones anatomicae universales pro no Gul. Haerweni medicum Leidenensem, etiam et aliis professoribus*, in 4to, 1616, vol. 87.—MS. notes of the 1652 College of Physicians in Harvey's Works, published by the Royal College of Physicians in 1786, were superintended by Dr. Mark Akenhead, it contains the two lectures, the account of the post-mortem examination of old Parr, and the sermons enumerated above. A translation of this volume by Dr. Willis, with Harvey's own, was published by the Sydenham Society, 8vo, Lond., 1849.

The following are the principal biographies of Harvey—in Aubrey, *Severall particulars of the Learned Physician*, in Lond., 1683; first published in 1685, the only contemporary account in Bayle's *Die Thomæ Harveyæ et Chirurge*, 1698 and 1720 (Eng. ed., 1788), in the *Biographia Britannica*, and in Aitken's *Biographical Memoirs*, the Latin Life by Dr. Lawrence, printed in the college edition of Harvey's Works in 1789; mentioned in Bayle's *Physiciens*, Lond., 1830, a Life by Dr. Robert Willis, founded on that by Lawrence, and reprinted in his English edition of Harvey in 1847, the much enlarged Life by the same author, published in 1878, the biography by Dr. Maund in the *Roll of the College of Physicians*, 2d ed., vol. 1, 1879.

The literature which has arisen on the great discovery of Harvey, on his methods and his merits, would fill a library. The most important contemporary writings have been mentioned above. The following list gives some of the most remarkable in modern times—the article in Bayle's dictionary quoted above, *Anatomical Lectures*, by Wm. Hunter, M.D., 1784, Sprengel's *Geschichte der Anatomie*, Halle, 1800, vol. iv., *Physiologie*, by J. B. Lamarck, 1854, Leves, *Physiology of Common Fish*, 1859, vol. 1, pp. 201-245, Cuvier, *Le Système de la Circulation du Sang*, Paris, 1857, *Die Entdeckung des Blutes*, ed. Michael Sever, Jena, 1876, Kiehn, *Die Entdeckung des Blutes*, Breslau, 1878, Willis, in his *Life of Harvey*, Wharton Jones, "Lectures on the Circulation of the Blood," *Lancet* for Oct. 25 and Nov. 1879, and the *Harveian Orations*, especially those by Dr. Stenking, Dr. Guy, and Prof. Rolleston. (P. H. S.)

HAARWICH, a municipal and parliamentary borough and seaport town of Essex, England, is situated on the extremity of a small peninsula projecting into the estuary of the Stour and Orwell, 70 miles N E of London by the Great Eastern Railway. It occupies an elevated situation, and a good view is obtained from Beacon Hill at the southern end of the esplanade. The town is somewhat irregularly built, but the streets though narrow are well paved. It is defended by a redoubt mounted with heavy guns and by three martello towers. The only public building of importance is the church of St Nicholas, an edifice of white brick in the perpendicular style, with stone buttresses and staple, erected in 1621 at a cost of £20,000. The harbour is one of the best on the east coast of England, and in stormy weather is largely taken advantage of for shelter. Its entrance is, however, encombred with rocks, and is dangerous without a pilot. The rapid accumulation of shingle threatened some years ago to block up the principal entrance, but this has been prevented by the construction of two breakwaters, having a length respectively of 1350 and 1000 feet. The shipping trade of the port was much injured by the removal, after the introduction of steamships, of the Hamburg and other packets from the station, but since the construction of the Great Eastern Railway steam packets have plied regularly between Harwich and Antwerp and Rotterdam. In 1876 1193 British ships entered the port with a tonnage of 299,227, and 38 foreign ships with a tonnage of 10,921. The number of British ships that cleared was 1233, with a tonnage of 296,095, and of foreign ships 28, with a tonnage of 8544. The principal imports are gum, timber, and tobacco, and the principal exports cement and fish. Shipbuilding has declined since the discontinuance of the Government dockyards. The prosperity of the town depends now largely on its shrimp and lobster fisheries, but there are also Roman cement works, breweries, and manufactures for artificial manure and for sail and tackle. It is much frequented for sea-bathing, and its suburb of Dovercourt possesses a chalybeate spring, the spa-house of which contains a library and museum. Harwich in all probability occupies the site of a Roman station. In 855 a great naval battle took place opposite the town between the Danes and the fleet of King Alfred, and in 1669 another took place between the Dutch and the English. Harwich was created a parliamentary borough by King Edward II in 1213 with the privilege of returning two members, but since the Reform Act of 1867 it has returned only one. The population of the municipal and parliamentary borough in 1871 was 6079.

HAIZ MOUNTAINS, THE (also spelt HAAZ, the German *Harzgebirge*, and the ancient *Silva Hercynia*), the most northerly mountain system of Germany, situated between the rivers Wesel and Elbe, occupy an area of about 786 square miles, of which 457 belong to Prussia, 286 to Brunswick, and 43 to Anhalt. Their greatest length extends in a S E and N W direction for about 56 miles, and their maximum breadth is about 20 miles. The group is made up of an irregular series of terraced plateaus, rising here and there into rounded summits, and intersected in various directions by narrow, deep valleys. The N W and higher part of the mass is called the Ober or Upper Haiz, the S E and more extensive part, the Unter or Lower Haiz, while the N W and S W slopes of the Upper Haiz form the Vothaiz. The Brocken group, which divides the Upper and Lower Haiz, is generally regarded as a part of the former. The prevalent upper geological formation of the whole district is greywacke and clay-slate, through which the granite here and there protrudes, as in the case of the Brocken. The highest summits of the Upper Haiz are the Brocken (3745 feet), the Heinrichshöhe (3402 feet), the Greater and Less Königberg (3376 feet and

3369 feet), and the Wurmberg (3182 feet), the Lower Haiz, the Auenberg (1870 feet), and the Vichtershöhe (1762 feet). The towns in the district, though not large, are tolerably numerous. The principal are—in the Upper Haiz, Goslar, Knansthal, Zellefeld, Andeasberg, Altenau, Lautenthal, Wildemann, Quid, Harzburg, Ilseburg, and Weingeroede, and in the Lower Haiz, Harzgerode, Ellingerode, Rubeland, Quedlinburg, Ballenstedt, Gamede, Suderode, Blankenburg, Thale, and Stolberg.

The chief industry is mining, which has been carried on since the middle of the 10th century. The Haiz is second only to the Erzgebirge among the mountains of Germany in mineral wealth. The most important mineral is a peculiarly rich argentiferous lead, but gold in small quantities, copper, iron, sulphur, alum, and arsenic are also found. Marble, granite, and gypsum are worked, and large quantities of vitrol are manufactured. The vast forests that cover the mountain slopes supply the materials for a very considerable trade in timber. Much wood is exported for building and other purposes, while in the Haiz itself no other fuel is used, whether for smelting the ores, which is done at the mines, or for domestic use. Employment is thus given to a large number of charcoal burners. The saw-dest of the numerous wood-factories is collected for use in the manufacture of paper. Tuff-cutting, coarse lace-making, and the breeding of canaries and native song birds also occupy many of the people. Agriculture is carried on chiefly on the plateaus of the Lower Haiz, but there is scarcely any pasturage both in the north and in the south. In the Lower Haiz, as in Switzerland, the cows, which carry bells hammerously tuned, are driven up into the heights in early summer, returning to the sheltered regions in late autumn.

The Haiz being the first obstacle to oppose the moist, cold winds from the North Sea, the northern summits are destitute of trees, but the lower slopes of the Upper Haiz are heavily wooded with pines and firs. Between the forests of these stretch numerous peat-mosses, which contain in their spongy recesses the sources of many small streams. On the Brocken are found one or two alpine and several alpine plants. In the Lower Haiz the forests contain a great variety of timber. The oak, elm, and birch are common, while the beech especially attains an unusual size and beauty. The walnut tree grows in the eastern districts.

The last bear was killed in the Haiz in 1705, and the last lynx in 1817, and since that time the wolf too has become extinct, but deer, foxes, wild cats, and badgers are still to be found in the forests.

The streams are very numerous, but are all small. While they are rendered extensively useful, by various skillful artifices, in working the mines underground, at other parts of their course they present the most picturesque scenery in all the picturesque Haiz. Perhaps the finest valley is the rocky Bode-thal, with the Ross Tappe, the Hexentanz-platz, the Baummannshöhle, and the Bielehöhle.

The inhabitants, about 70,000 in number, are descended from various stocks. The Upper and Lower Saxon, the Thuringian, and the Frankish races have all contributed to form the present people, and their respective influences are still to be traced in the varieties of dialect. The boundary line between High and Low German passes through the Haiz.

The Haiz is now one of the most frequented tourist resorts of Germany. It is traversed by excellent roads in all directions, and is completely girt by railways from the principal towns of the empire. The chief point of interest is undoubtedly the Brocken or Blockberg, famous as the scene of the "Walpurgisnacht" in Goethe's *Faust*, as well as for the atmospheric phenomena of which the "spectre of the Brocken" (see HALO) is the best known. The Haiz was the last stronghold of paganism in Germany, and to that fact are due the weird legends, in which no district is

heads to be cast down among the crowd. Husein was intercepted on the borders of Babylonia by Hant, with a company of horse, who told him he had orders to bring him alone to Kufa, but allowed him to proceed by what route he chose without losing sight of him. A horseman met them on the road with secret orders from 'Obaidallah to lead Husein into an open and undefended place, and halt until 'Amer, the commander of the Syrian army, arrived with his forces. This happened the next day, and Husein and his small escort were surrounded by 4000 horse, and slaughtered, after a stubborn resistance, on the plain of Karbela by the banks of the Euphrates, under peculiarly tragic circumstances, in little son 'Abdallah, and his nephew, a beautiful child, both being murdered in his arms. This took place on the 10th of Moharram 61 A. H. (680 A. D.), and is commemorated during that month by the Shi'ahs in India and Persia, a long music play being performed, the scenes of which are carried on from day to day, and culminate in carrying out the *tabut* or coffin of the martyrs to an open place, generally the cemetery, or in sea-side places to the sea-shore.

The cause of 'Ali and his family was warmly espoused by the Persians, who had been forced to embrace Islam, but who regarded the Sunnah or Semitic law with especial repugnance. The party were known as Shi'ahs, "Sectarians," and as the quarrel between Jew and Christian thus perpetuates the old enmity between Jew and Gentile, between the Semitic and Aryan races, it has produced an irreparable breach in Islam.

The passion play of *Husein and Husein* has been published in English by Sir Lewis Pelly (London, 1879, 2 vols. 8vo) from the dictation of native teachers and performers of the drama. (E. H. P.)

HASBEYA, or **HASBERRYA**, a town of the Druses, about 36 miles west of Damascus, is situated at the foot of Mount Hermon in Syria, overlooking a deep amphitheatre, from which a brook flows to the Hasbani. Both sides of the valley are planted in terraces with olives, vines, and other fruit trees. The grapes are either dried, or made into a kind of syrup. About four fifths of the inhabitants are Christians, and in 1846 an American Protestant mission was established in the town. This little community suffered much persecution at first from the Greek Church, and afterwards from the Druses, by whom in 1860 nearly 1000 Christians were massacred, while others escaped to Tyre or Sidon. The castle in Hasbeya was held by the crusaders under Count Orian, but in 1171 the Druse emirs of the great Shahaab family (see *Druses*) recaptured it. In 1206 this family was confirmed in the lordship of the town and district, which they held till the Turkish authorities took possession of the castle in the present century. Near Hasbeya are bitumen pits let by Government, and to the north, at the source of the Hasbani, the ground is volcanic. Some travellers have identified Hasbeya with the Biblical Baal-Gad, or Baal-Hermon,—a supposition rendered the more likely by the ruins of several temples near the town. Population about 5000.

HASDRUBAL. Of the bears of this very common Carthaginian name the most famous are the following—

1. One of the leaders of the popular party at the close of the First Punic War. He was conspicuous for his dexterous management in politics and his conciliatory manners. He married the daughter of Hamilcar Barca, and his skilful and cordial co-operation was of enormous consequence to Hamilcar during his Spanish wars. He went to Spain with his father-in-law, but soon returned to Carthage, where his talents were specially needed to conduct the party at home. He was, however, in Spain when Hamilcar fell (239), and was soon formally appointed by the home Government to the command which he had at once assumed. Devoting himself most successfully to the task

of consolidating the Carthaginian power in Spain, he founded New Carthage as the Spanish capital, and married the daughter of a Spanish chief. His kindly and generous manner attached the natives to him, and brought many over to the Carthaginian alliance. In 221 he fell by the hand of an assassin. The account given of him by Polybius is much more favourable and far more trustworthy than that of the Roman author Fabius whom he refutes.

2. The second son of the great Hamilcar. He was left by Hannibal as commander in Spain (219 B. C.), where he had to contend with the two Scipios, Cneius and Publius. Three years were spent in desultory warfare, in which the Romans were generally successful. After the battle of Cannæ, Hasdrubal was ordered to march into Italy, while Hannibal was sent from Carthage with a fresh army to supply his place. But a decisive battle on the Ebro, in which he was totally defeated, checked his northward march. It is hardly possible to exaggerate the importance of this battle. Had a fresh Carthaginian army joined Hannibal in Italy for the campaign of 215 or 214, the danger to Rome would have been infinitely increased. Several years now passed, marked by the Roman historians with fresh Roman victories, and it is certain that the struggle continued doubtful till 212, when both the Scipios were defeated and slain. In spite of this great success, Hasdrubal was not at the moment able to begin the march on Italy.

The Romans were skillfully rebuffed by Lucius Magonius, and in 211 a fresh army under the pretor Nero landed in Spain. At the same time there seems to have been no co-operation among the Carthaginian generals, and when the younger Scipio landed in Spain (210) he found their armies widely separated. Taking advantage of this, Scipio by a sudden attack (206) captured New Carthage, which contained vast military stores, all the Spanish hostages, and 10,000 captives. To achieve this brilliant success he had to leave the road northwards undefended, and although he rapidly returned and (according to the Roman accounts) defeated Hasdrubal at Bæcula in Andalus, the Carthaginian general was able to make his way with a strong army to the Pyrenees, which he crossed in safety near the western extremity. The whole course of the Spanish war, and especially the chronology of these later events, are very obscure. At all events Hasdrubal, after a very rapid and skilful march across the whole breadth of Gaul, appeared early in 207 in the north of Italy. When once he had succeeded in getting out of Spain, this brilliant march proved Hasdrubal worthy of his father and his brother, and long as it had taken to carry out his plan, we must remember that after the Romans perceived the necessity of keeping him back from Italy the difficulties in his way were enormous. On hearing of the passage of the Pyrenees, the Romans availed extraordinary levies, but before they had taken any steps to meet him, Hasdrubal was already in Cisalpine Gaul. Hannibal was still in Apulia, perhaps not expecting his brother so soon. Hasdrubal sent to meet him two Numidian horsemen with four Gauls, who almost at the end of their perilous journey fell into the hands of the consul Nero. In the meantime Hasdrubal had advanced into Umbria, where the plebeian consul Livius was encamped near Sena. Nero, with 7000 men, left his own camp, and by a rapid march, which must be ranked among the most important events of the war, joined his colleague. The united army was much too strong for Hasdrubal. He tried to avoid a battle, but his guides failed him, and he was forced to fight on the south bank of the Metaurus. A long and bloody conflict resulted in the complete defeat of the Carthaginians, and Hasdrubal, after all was lost, fell sword in hand in the midst of the enemy. His head, which was thrown by Nero's soldiers into Hannibal's camp, first revealed to the latter his brother's defeat and the ruin of the Carthaginian cause.

HASLINGDEN, a market town of Lancashire, England, is situated 7 miles S E of Blackburn, in a hilly district on the borders of the forest of Rossendale, and is supposed to come to derive its name from the havel trees which at one time abounded in its neighbourhood. The town formerly stood on the slope of a hill, but the modern part, which is substantially built of stone, has been erected at its base. The parish church dedicated to St James was, with the exception of the tower, which dates from the time of Henry VIII, rebuilt in 1780, and the whole structure was rebuilt in 1879. Hundreds of schools are attached, to which there is an endowment for ten poor boys, founded in 1719. The principal other buildings are the mechanics' institute, the town hall, where the sessions and county court are held, and the public hall for assemblies. The woollen manufacture, formerly the staple of the town, has now been superseded by that of cotton, and there are also silk manufactures, iron works, and size works. In the vicinity there are collieries and quarries for stone, flags, and slate. The population of the town in 1861 was 6959, and 7098 in 1871, and that of the township was 10,109 and 12,000.

HASSEPE, a town of Prussia, province of Westphalia, government district of Ainsberg, and circle of Hagen, is situated in the valley of the Ennepee between the Hagen and strempenau, the river, and the railway from Dusseldorf to Dortmund, 23 miles north east of Dusseldorf. It has iron foundries, rolling mills, puddling forges, and manufactures of iron, steel, and brass wares, and of machines. Haspe was raised to the rank of a town in 1874. The population in 1875 was 7030.

HASSAN, a district of Mysore, India, lying between 12° 30' and 13° 22' N lat and between 75° 32' and 76° 58' E long. It is bounded on the S W by the Madras district of South Kanara, and on the S E partly by the state of Coorg. The main portion of the district consists of the river basin of the Hemavati and its tributaries. It naturally divides into two portions, the Malnad or hill country, which includes some of the highest ranges of the Western Ghats, and the Malnad or plain country, sloping towards the south. The Hemavati, which flows into the Cauvery in the extreme south, is the great river of the district, its most important tributary is the Yagachi. The upper slopes of the Western Ghats are abundantly clothed with magnificent forests, and wild animals of all sorts abound. Among the mineral products are krolin, talpa, and quartz. The soil of the valleys is a rich red alluvial loam.

The area extends to 3201 square miles. The census of 1871 returned the inhabitants at 667,961—320,097 males and 347,864 females—the Hindu numbering 320,577, Mohammedans 24,460, Jains 1054, Christians 5670. Hassan town and Mysore each contain more than 5000 inhabitants. The staple crops consist of sugar, rice, tobacco, and cotton, the coco-nut and rice not palm, grain, fruit trees, and chilies. Coffee cultivation has been the success of late years. The first plantation was opened in 1843, and now there are 175 coffee estates owned by Europeans and 8500 native holdings. The statistics of migration show a total of 9565 tanks in the district and 215 miles of canals. The exports are large, consisting chiefly of food grains and coffee. The imports are European goods, hardware of all sorts, and spices. The largest weekly fair is held at Alur. The annual religious gathering and fair, attended by about 10,000 persons, takes place on every year at Madalur. The gross revenue amounted in 1872-73 to £126,808, and the police force (1874) numbered 470 men of all ranks, maintained at a cost of £2699. There were 248 schools in 1874 aided by Government, attended by 1870 pupils, and 147 unaided with 1657 pupils. The average mean temperature of the district is 76°, and the average rainfall at Hassan town during seven years was 85 inches. In the Ghats as much as 100 inches sometimes fall in the year. Malaria fever prevails in the Malnad during the early rains.

The real history of Hassan does not begin until the epoch of the Bahlija dynasty, which lasted from the 10th till the 14th century. Their capital was at Srirangapatna, the ruins of which are still to be seen scattered round the village of Hehnd in this district. The earlier kings professed the Jain faith, but the finest temples were

erected to Siva by the later monarchs of the line. While they were at the zenith of their power the whole of southern India acknowledged their sway. After the Mahometan invasion in the 14th century, the district of Hassan ceased to exist in the seat of a metropolis, and became a remote province known as Bahlija. Since 1812 the district, with the rest of Mysore, has been under direct British administration.

HASSAN See ASSASSINS, vol II p 723

HASSEPE, JOHANN ADOLPH (1699-1783), a musical composer, is a striking instance of the instability of fame. One of the most prolific and most celebrated composers of the 18th century, he is now all but forgotten, and his extant works rest quietly on the shelves of public libraries. He was born at Dusseldorf near Hamburg, on March 25, 1699, and received his first musical education from his father. Being possessed of a fine tenor voice, he chose the theatrical career, and joined the operatic troupe conducted by Reinhard Keiser at Hamburg, the same Keiser in whose orchestra Handel had played the second violin some years before. Hasses's success led to an engagement at the court theatre of Brunswick, and it was there that, in 1723, he made his debut as a composer with the opera *Antigonus*. The success of this first work induced the duke to send Hasses to Italy for the completion of his studies, and in 1721 he went to Naples and placed himself under the tuition of the celebrated Porpora, with whom, however, he seems to have disagreed both as a man and as an artist. On the other hand he gained the friendship of Alessandro Scarlatti, to whom he owed his first commission for a sarsenda for two voices, sung at a family celebration of a wealthy merchant by two of the greatest singers of Italy, Fainelli and Signora Tesi. This event established Hasses's fame, he soon became very popular by the name of "il caro Sassone," and his opera *Sessant'ato*, written for and produced at the Royal Opera at Naples in 1726, made his name known all over Italy. At Venice, where he went in 1727, he and his works were received with equal favour. It was there that he became acquainted with the celebrated singer Faustina Bordoni, better known as Faustina Hasses, for she became the composer's wife in 1730. The artist couple soon afterwards went to Dresden, in compliance with a brilliant offer made to them by the splendidly loving elector of Saxony, Augustus II. Thero Hasses remained for two years, after which he again journeyed to Italy, and also in 1733 to London, in which latter city he was tempted by the aristocratic clique inimical to Handel to become the rival and antagonist of that great master. But this he modestly and wisely declined, remaining in London only long enough to superintend the rehearsals for his opera *Artace*. All this while Faustina had remained at Dresden, the declared favourite of the public and unfortunately also of the elector, her husband, who remained attached to her, being allowed to see her only at long intervals. In 1730, after the death of Augustus II, Hasses settled permanently at Dresden till 1763, when he and his wife retired from court service with considerable pensions. But Hasses was still too young to rest on his laurels. He went with his family to Vienna, and added several operas to the great number of his works already in existence. His last work for the stage was the opera *Ruggiero*, written for the wedding of Archduke Ferdinand at Milan. On the same occasion a diaphanous cantata by Mozart, then (1771) fourteen years old, was performed, and Hasses is said to have prophesied Mozart's future greatness much in the same manner as Mozart himself predicted that of Beethoven. By desire of his wife Hasses settled at his birthplace Vienna, and there he died December 23, 1783. His compositions were innumerable, including as many as 180 operas, besides oratorios, cantatas, masses, and almost every variety of instrumental music. It would be needless to criticize or give the titles of these compositions, for most of them are,

is was said before, totally and not unjustly forgotten. Moreover, comparatively few of them have escaped destruction. During the siege of Dresden by the Prussians in 1760, most of his manuscripts, collected for a complete edition to be brought out at the expense of the elector, were burnt some of his works, amongst them an opera *Alcide al Brío*, have been published, and the libraries of Vienna and Dresden possess the autographs of others. Hasse's instrumentation is certainly not above the low level attained by the average musicians of his time, and his *ensembles* do not present any features of interest. In dramatic fire also he was wanting, but he had a fund of gentle and genuine melody, and by this fact his enormous popularity during his life must be accounted for. The two arias which Fainell had to repeat every day for ten years to the melancholy king of Spain, Philip V., were both from Hasse's work. Of Faustina Hasse, almost as celebrated as her husband, most that is necessary has been said above. It will be sufficient to add that she was born at Venice in 1700, sang at Vienna, London (under Handel, 1726), and Dresden, and was, according to the unanimous verdict of her critics (including Dr Bunney), one of the greatest singers of a time rich in vocal artists. The year of her death is not exactly known. Most probably it shortly preceded that of her husband.

HASSELQUIST, FREDERICK (1722-1759), a Swedish traveller and naturalist, was born near Linköping in East Gothland, 3d January 1722. He lost his father at an early age, and his uncle, his sole remaining protector, in his thirteenth year, but succeeded by means of private teaching in supporting himself while continuing his education. In 1741 he entered the university of Upsala, where his taste for the study of nature was fostered and developed by Linnaeus, and where in 1747 he obtained licence in medicine, and published a thesis entitled *De Viribus Plantarum*. On account of the frequently expressed regrets of Linnaeus at the lack of information regarding the natural history of Palestine, Hasselquist resolved to undertake a journey to that country, and a sufficient subscription having been obtained to defray expenses, he, after making himself acquainted with the languages of the Levant, embarked for Smyrna, where he arrived November 20, 1749. He visited most of Asia Minor, Egypt, Cyprus, and Palestine, and made large natural history collections, but his constitution, actually weak, gave way under the fatigues and anxieties of travel, and he died at Smyrna, February 9, 1753, on his way homewards. His collections reached home in safety, and five years after his death the results of his wanderings were published by Linnaeus under the title *Resa till Telaga Sanderi Förfärd, 1749 till 1753*. The work is divided into two parts, the first consisting of the traveller's journal and letters, and the second of his remarks on the botany, zoology, and mineralogy of the countries through which he passed, with observations on the prevalent diseases and then on the state of industry, commerce, and the arts. It was translated into French and German in 1762, and into English in 1766.

HASSELT, a town of Belgium, capital of the province of Limburg, is situated on the Demer and on the railway from Aix-la-Chapelle to Maestricht, 20 miles north-west of Liège. It possesses two churches, a hospital, a spacious town hall, an atheneum, and a public library. Tobacco and madder are cultivated in the neighbourhood. The principal manufactures are linen, lace, brandy, and beer. At Hasselt the Dutch under the prince of Orange gained a victory over the Belgians under General Daine, 6th May 1831. The population in 1876 was 11,561.

HASSENPLUG, HANS DANIEL LUDWIG FREDERICK (1793-1862), a minister of state in Hesse-Cassel, celebrated as a reactionary, was born at Hanau, in the elec-

torate of Hesse, in 1793. He studied law at Göttingen, and was appointed by the elector Frederick William I (then acting as regent) to a subordinate post in that university. He rose rapidly, and proved himself a man of great resolution and energy. From the first he adopted that line of policy which made him so disliked throughout his career. He evicted, that is to say, a suspicious censorship over the press, he reduced to a shadow the power of the legislative chambers, he introduced new and harsh measures of army discipline, and contended relentlessly with all disciples of free thought. In the matter of education he showed praiseworthy zeal, and promoted as far as he could the national schools of Hesse. But the services he rendered in this way were not sufficient to induce the mass of the people to pardon the reactionary tendency of his general policy, and he was obliged in 1837 to flee from the general hatred he had encountered. He found shelter in Prussia, where the Government entrusted him with the discharge of various judicial offices, and he remained in Prussia till the full tide of reaction had set in after the year 1848. He then (1850) returned to Hesse-Cassel, the ministry of the revolution of 1848 having been dismissed. Despite the fact that Hassenpflug had never freed himself from a charge of peculation brought against him in the performance of his judicial duties in Prussia, he was appointed by the elector of Hesse to the head of the new ministry. He acted at once on the old lines, levying taxes without the consent of the chambers, dissolving them when they protested, and finally proclaiming martial law. The soldiers rose, the officers being on the side of the people, the Government was in so precarious a condition that it seemed wise to the elector to flee with his court to Wilhelmshof. Partly by the influence of Hassenpflug the German burdoisnath (or council of all the states) espoused the cause of the elector against his subjects, and by the end of the year (1850) the estate minister had the satisfaction of seeing the reactionary Government (with himself as minister of finance) reinstated in power. His position was, however, difficult, owing to his great unpopularity among all classes. When in 1852 the brother of the elector assaulted him in a fit of lunacy, Hassenpflug at once sent in his resignation, but it was not accepted till 1855. He then retired to Marburg (in Hesse), where he died October 15, 1862. His friend Dr Vilmar, who pronounced his funeral oration, dwelt chiefly on the piety of the deceased, who he said never travelled without a copy of the New Testament.

HASTINAPUR, an ancient city of India, in the Meerut district, North-Western Provinces, lying on the bank of the Burgang, or former bed of the Ganges, 23 miles N.E. of Meerut. It formed the capital of the great Pundrawa kingdom, celebrated in the *Mahabharata*, and probably one of the earliest Aryan settlements outside the Punjab. Few traces of the ancient city now remain, but tradition points to a group of shapeless mounds as the residence of the children of the moon, the Lunar princes of the house of Bhārata whose deeds are commemorated in the great national epic. After the conclusion of the famous war which forms the central episode of that poem, Hastinapur remained for some time the metropolis of the descendants of Paishshi, but the town was finally swept away by a flood of the Ganges, and the capital was transferred to Kanauib.

HASTINGS, a municipal and parliamentary borough and market-town of Sussex, England, the principal of the Cinque Ports, is picturesquely situated on the southern coast of England, 74 miles from London by the London, Brighton, and South Coast Railway, and 62 by the London and South-Eastern Railway. It lies in two gorges, surrounded by an amphitheatre of hills and cliffs on every side except the south. At the beginning of the century, when

it first came into reputation as a watering place, Hastings consisted of two main streets, but since then many new streets and squares have been added, and St Leonards, at that time about a mile distant, is now connected with it by a line of terraces and parades, and forms its more fashionable district. On the brink of the western cliff still stand a square and a circular tower of the old castle, probably erected soon after the time of William the Conqueror, and the ruins, opened up by excavation in 1824, of the castle chapel, a transitional Norman structure 110 feet long, with a nave, chancel, and aisle. Besides the chapel, there was also at one time a college, both being under the control of a dean and secular canons. The doctory was at one time held by Thomas a Becket, and one of the canons by William of Wykeham. The principal public buildings are the old parish churches of All Saints and St Clements, both in the Perpendicular style, the former containing in its register for 1619 the baptism of Titus Oates, whose father was rector of the parish, and the latter two houses to Thomas Weekes (d 1593) and John Bauley (d 1592), the town hall, erected in 1823, the music hall, erected in 1859, the assembly room, the Roman Catholic college, the Augustinian monastery, and the Albert memorial and drinking fountain, erected in 1861. Among the industries of the town are fishing, boat building, and coach-making, but its prosperity depends chiefly upon its reputation as a watering-place. Its popularity in this respect is owing to its historical interest, its picturesque situation, the many beautiful walks in the neighbourhood, its fine level sands, and its healthy climate, which, while bracing and vigorous in the higher parts of the town, is in its lower parts specially suited from its mildness, for sufferers from pulmonary complaints. The town is well supplied with hotels, reading rooms, and pleasure gardens, and possesses a line of parades extending along the coast for nearly 3 miles. The Marina, a covered parade 600 feet in length, was built in 1823. There is a fine pier, opened in 1872, 900 feet in length, and possessing a pavilion capable of seating nearly 3000 persons. A public park, 70 acres in extent, is at present being laid out. The sewage of the town is conveyed a considerable distance out to sea before it is discharged. The area of the municipal borough is 1636 acres, and of the parliamentary borough 4617 acres. The population of the municipal borough in 1871 was 29,391, and of the parliamentary borough 33,337.

Hastings is of great antiquity, and was a place of some importance in the time of the Angles. Saxon names derive its name from Hæsten, a Danish pirate who ravaged it about the time of Alfred the Great. According to the French biographies of Edward the Confessor, it is so called from the hasty manner in which William I. secured its fortifications. It is mentioned in the chronicles as *Hæstingæ*, and is reckoned as distinct from the shire of Sussex. In the Bayeux tapestry it is called *Hastings æstria*. A mint was established at it by Athelstan in 824, of which there is some notice in the Domesday Book. In 1049, according to the Waverley Chronicle, its seven distinguished themselves in the pursuit of the pirate Swein after the murder of Boon, and took two of his ships. Like the other principal seaports on the southern coast, it was garrisoned by Harold in 1066, and was the scene of the battle of the Conqueror, to whom, however, it surrendered without striking a blow, and who selected it as the site of a permanent camp, and erected a wooden fortress on the cliff on which the castle was afterwards built. From this camp William, on the morning of October 14th, 1066, set out to meet Harold at the Senlac Hill, and after his great victory there he returned to it, and remained encamped five days in the hope of recovering the homage of the English. The site of the original town is supposed to be now a great flat covered by the sea. By a treaty of William the Conqueror Hastings, together with Hythe, was added to the three previously incorporated ports of Sandwich, Dover, and Romney, and invested with certain privileges, the five being afterwards known as the Cinque Ports. In the reign of Edward I. it was rated at 21 ships with 21 seamen in each, for the service of the king for fourteen days at his own charge. In 1377 the town was burned down by the French, but it is soon afterwards rebuilt. The harbour has fallen much since the time of Elizabeth, when the wooden pier was destroyed by a storm, it does not now ad-

mit vessels above 100 tons to enter, and this only, at full tide. The town received a charter of incorporation from Elizabeth in 1568, which was confirmed and enlarged by Charles II. In the 42d of Edward III. it obtained the privilege of retaining two members to parliament.

HASTINGS, WARREN (1732-1818), the first governor-general of British India, was born on the 6th of December 1732 in the little hamlet of Churchill in Oxfordshire. His father was a family which had been settled for many generations in the adjoining village of Daylesford, but his great grandfather had sold the ancestral manor house, and his grandfather had been unable to maintain himself in possession of the family living. His mother died a few days after giving him birth, his father, Thomas Hastings, drifted away to perish obscurely in the West Indies. Thus unfortunate in his birth, young Hastings received the elements of education at a charity school in his native village. At the age of eight he was taken in charge by an elder brother of his father, Howard Hastings, who held a post in the customs. After spending two years at a private school at Newington Butts, he was moved to Westminster, where among his contemporaries occur the names of Lord Thurlow and Lord Shelburne, Sir Elijah Impey, and the poets Cowper and Churchill. In 1749, when his headmaster Dr. Nichols was already anticipating for him a successful career at the university, his uncle died, leaving him to the care of Mr. Chiswick, who, by the suggestion of the East India Company, was determined to send his ward to seek his fortune as a "writer" in Bengal.

When Hastings landed at Calcutta in October 1750, the affairs of the East India Company were at a low ebb. Throughout the entire south of the peninsula French influence was predominant. The settlement of Fort St. George or Madras, captured by force of arms, had only recently been restored in accordance with a clause of the peace of Aix-la-Chapelle. The loud genius of Duplex everywhere overwhelmed the native imagination, and the star of Clive had scarcely yet risen above the horizon. The rivalry between the English and the French, which had already convulsed the south, did not penetrate to Bengal. That province was under the able government of Ali Vaidi Khan, who peremptorily forbade the foreign settlers at Calcutta and Chandanagar to introduce funds from Europe. The duties of a young "writer" were then such as are implied in the name. At an early date Hastings was placed in charge of an *awany* or factory in the interior, where his duties would be to superintend the weaving of silk and cotton goods under a system of money advances. In 1755 he was transferred to Kámbházar, the river-port of the native capital of Mughalshábad. In 1756 the old nawab died, and was succeeded by his grandson Asaf-ud-Daulah, a spoils boy of 19, whose name is indelibly associated with the tragedy of the Black Hole. When that passionate young prince, in revenge for a fancied wrong, resolved to drive the English out of Bengal, his first step was to occupy the fortified factory at Kámbházar, and make prisoners of Hastings and his companions. Hastings was soon released at the intercession of the Dutch resident, and made use of his position at Mughalshábad to open negotiations with the English fugitives at Faiza, the site of a Dutch factory near the mouth of the Hooghly. In later days he used to refer with pride to his services on this occasion, when he was first initiated into the wiles of Oriental diplomacy. After a while, he found it necessary to fly from the Mahomedan court, and join the main body of the English at Faiza. When the relieving force arrived from Madras under Colonel Clive and Admiral Watson, Hastings enrolled himself as a volunteer, and took part in the action which led to the recovery of Calcutta. Clive showed his appreciation of Hastings's merits, by appointing him in 1758 to the important post of resident at the court of Mughal-

dabad It was there that he first came into collision with the Bengali Brahman, Nandikumar, whose subsequent fate throws so deep a shadow upon his own fair fame. During his three years of office as resident he was able to render not a few valuable services to the Company, but it is more important to observe that his name nowhere occurs in the official lists of those who derived pecuniary profit from the necessities and weakness of the native chiefs. In 1761 he was promoted to be member of council, under the presidency of Mr Vansittart, who had been introduced by Clive from Madras. The period of Vansittart's government has been truly described as "the most revolting page of our Indian history." The entire duties of administration were suffered to remain in the hands of the nabab, while a few irresponsible English traders had drawn to themselves all real power. The members of council, the commanders of the troops, and the commercial residents plundered on a grand scale. The youngest servant of the Company claimed the right of trading on his own account, free from taxation and from local jurisdiction, not only for himself but also for every native subordinate whom he might permit to use his name. It was this exemption, threatening the very foundations of the Mussulman government, that finally led to a rupture with the nabab. Macaulay, in his celebrated essay, has said that "of the conduct of Hastings at this time little is known." As a matter of fact, the book which Macaulay was professing to review describes at length the honourable part consistently taken by Hastings in opposition to the great majority of the council. Sometimes in conjunction only with Vansittart, sometimes absolutely alone, he protested unceasingly against the policy and practices of his colleagues. On one occasion he was stigmatised in a minute by Mr Batson with "having opposed the nabab's cause, and as a hired solicitor defended all his actions, however dishonourable and detrimental to the Company." An altercation ensued. Batson gave him the lie, and struck him in the council chamber. When war was actually begun, Hastings officially recorded his previous resolution to have resigned, in order to repudiate responsibility for measures which he had always opposed. Waiting only for the decisive victory of Buxar over the allied forces of Bengal and Oudh, he resigned his seat and sailed for England in November 1764.

After fourteen years' residence in Bengal Hastings did not return home a rich man, as estimated by the opinion of his position according to the custom of the time he had augmented his slender salary by private trade. At a later date, he was charged by Burke with having taken up profitable contracts for supplying bullocks for the use of the Company's troops. It is admitted that he conducted by means of agents a large business in timber in the Gangetic sandarbans. When at Falta he had married Mrs Campbell, the widow of an officer. She bore him two children, of whom one died in infancy at Murshidabad, and was shortly followed to the grave by her mother. Their common graveside is in existence at the present day, bearing date July 11, 1749. The other child, a son, was sent to England and also died shortly before his father's return. While at home Hastings is said to have attached himself to literary society, and it may be inferred from his own letters that he now made the personal acquaintance of Samuel Johnson and Lord Mansfield. In 1766 he was called upon to give evidence before a committee of the House of Commons upon the affairs of Bengal. The good sense and clearness of the views which he expressed caused attention to be paid to his desire to be again employed in India. His pecuniary affairs were embarrassed, partly from the liberality with which he had endowed his few surviving relatives. The great influence of Lord Clive was also exercised on his behalf. At last,

in the winter of 1768, he received the appointment of second in council at Madras. Among his companions on his voyage round the Cape were the Baron Imhoff, a speculative portrait painter, and his wife, a lady of some personal attractions and great social charm, who was destined henceforth to be Hastings's life long companion. Of his two years' work at Madras it is needless to speak in detail. He won the good-will of his employers by devoting himself to the improvement of their manufacturing business, and he kept his hands clean from the prevalent taint of pecuniary transactions with the nabab of the Carnatic. One fact of some interest is not generally known. He drew up a scheme for the construction of a pier at Madras, to avoid the dangers of landing through the surf, and instructed his brother-in-law in England to obtain estimates from the engineers Brindley and Smeaton.

In the beginning of 1772 his ambition was stimulated by the nomination to the second place in council at Bengal with a promise of the reversion of the governorship when Mr Cartier should retire. Since his departure from Bengal in 1764 the situation of affairs in that settlement had scarcely improved. The second governorship of Clive was marked by the transfer of the *diwani* or financial administration from the Mogul emperor to the Company, and by the enforcement of stringent regulations against the besetting sin of population. But Clive was followed by two inefficient successors, and in 1770 occurred the most terrible Indian famine on record, which is credibly estimated to have swept away one-third of the population. In April 1772 Warren Hastings took his seat as president of the council at Fort William. His first care was to carry out the instructions received from home, and effect a radical reform in the system of government. Clive's plan of governing through the agency of the native court had proved a failure. The directors were determined "to stand forth as *Hindus*, and take upon themselves by their own servants the entire management of the revenues." All the officers of administration were transferred from Murshidabad to Calcutta, which Hastings boasted at this early date that he would make the first city in Asia. This reform involved the ruin of many native reputations, and for a second time brought Hastings into collision with the wily Brahman, Nandikumar. At the same time a new settlement of the land revenue on leases for five years was begun, and the police and military systems of the country were placed upon a new footing. Hastings was a man of immense industry, with an insatiable appetite for details. The whole of this large series of reforms was conducted under his own personal supervision, and upon no part of his multifarious labours did he dwell in his letters home with greater pride. As an independent measure of economy, the stipend paid to the titular nabab of Bengal, who was then a minor, was reduced by one-half—to sixteen *laks* a year (say £160,000). Macaulay imputes this reduction to Hastings as a characteristic act of financial immorality, but in truth it had been expressly enjoined by the court of directors, in a despatch dated six months before he took up office. His pecuniary bargains with Syah Daula, the nabab wazir of Oudh, stand on a different basis. Hastings himself always regarded them as incidents in the general scheme of his foreign policy. The Maharrattas at this time had got possession of the person of the Mogul emperor, Shah Alam, from whom Clive obtained the grant of Bengal in 1765, and to whom he assigned in return the districts of Allahabad and Kora and a tribute of £300,000. With the emperor in their camp, the Maharrattas were threatening the province of Oudh, and causing a large British force to be cantoned along the frontier for its defence. Warren Hastings, as a deliberate measure of policy, withheld the tribute due to the emperor,

and resold Allahabad and Kora to the wazir of Oudh. The Mahatta retreated, and all danger for the time was dissipated by the death of their principal leader. The wazir now bethought him that he had a good opportunity for satisfying an old quarrel against the adjoining tribe of Rohillas, who had played fast and loose with him while the Mahatta army was at hand. The Rohillas were a race of Afghan origin, who had established themselves for some generations in a fertile tract west of Oudh, between the Himalayas and the Ganges, which still bears the name of Rohilkhand. They were not so much the occupiers of the soil, as a dominant caste of warriors and freebooters. But in those troubled days their title was as good as any to be found in India. After not a little hesitation, Hastings consented to allow the Company's troops to be used to further the ambitious designs of his Oudh ally, in consideration of a sum of money which relieved the over-pressing wants of the Bengal treasury. The Rohillas were defeated in fair fight. Some of them fled the country, and so far as possible Hastings obtained terms for those who remained. The fighting, no doubt, on the part of the wazir was conducted with all the savagery of Oriental warfare, but there is no evidence that it was a war of extermination.

Meanwhile, the affairs of the East India Company had again come under the consideration of Parliament. The Regulating Act, passed by Lord North's ministry in 1773, effected considerable changes in the constitution of the Bengal Government. The council was reduced to four members with a governor-general, who were to exercise certain indefinite powers of control over the presidencies of Madras and Bombay. Hastings was named in the Act as governor-general for a term of five years. The council consisted of General Clive and the Hon. Colonel Monson, two third-rate politicians of considerable parliamentary influence, Philip Francis, then only known as an able permanent official, and Burwell, of the Bengal Civil Service. At the same time a supreme court of judicature was appointed, composed of a chief and three puisne judges, to exercise an indeterminate jurisdiction at Calcutta. The chief-justice was Sir Elijah Impey, already mentioned as a schoolfellow of Hastings at Westminster. The whole tendency of the Regulating Act was to establish for the first time the influence of the crown, or rather of parliament, in Indian affairs. The new members of council disembarked at Calcutta on the 19th of October 1771, and on the following day commenced the long feud which so early terminated twenty-one years later with the acquittal of Warren Hastings by the House of Lords. Macaulay states that the members of council were put in ill-humour because their salute of guns was not proportionate to their dignity. In a contemporary letter Francis thus expresses the same petty feeling: "Surely Mr. H might have put on a ruffled shirt." Taking advantage of an ambiguous clause in their commission, the majority of the council (for Burwell uniformly sided with Hastings) forthwith proceeded to pass in review the recent measures of the governor-general. All that he had done they condemned, all that they could they reversed. Hastings was reduced to the position of a cipher at their meetings. After a time they lent a ready ear to detailed allegations of corruption brought against him by his old enemy Nandikumar. To charges from such a source, and brought in such a manner, Hastings declined to reply, and referred his accuser to the supreme court. The majority of the council, in their executive capacity, resolved that the governor-general had been guilty of peculation, and ordered him to refund. A few days later Nandikumar was thrown into prison on a stale charge of forgery, tried before the supreme court sitting in bail, found guilty by a jury of Englishmen, and sentenced to be hanged. That Hastings set this prosecution in motion, no

reasonable person can doubt, and it is equally clear that Chief Justice Impey is free from all personal blame. The majority of the council abandoned their supporter, who was executed in due course. He had forwarded a petition for reprieve to the council, which Clive and Impey took care should not be presented in time, and which was subsequently burnt by the common hangman on the motion of Francis. At the time no one dared to impute to Hastings the crime of a judicial murder. But though he had thus silenced the charges brought against him, a combination of circumstances placed him in a position of fresh difficulty. While the strife was at its hottest, he had sent an agent to England, with a general authority to place his resignation in the hands of the Company under certain conditions. The agent thought fit to exercise that authority. The resignation was promptly accepted, and one of the directors was appointed to the vacancy. But in the meantime Colonel Monson had died, and Hastings was thus restored, by virtue of his casting vote, to the supreme management of affairs. He refused to ratify his resignation, and when Clive and Impey attempted to seize on the governor-generalship, he judiciously obtained an opinion of the supreme court in his own favour. From that time forth, though he could not always command an absolute majority in council, Hastings was never again subjected to gross insult, and his general policy was able to prevail.

A crisis was now approaching in foreign affairs which demanded all the experience and all the genius of Hastings for its solution. Bengal was prosperous, and free from external enemies on every quarter. But the Government of Bombay had hurried on a rupture with the Mahatta confederacy at a time when France was on the point of declaring war against England, and when the mother-country found herself unable to subdue her rebellious colonists in America. Hastings did not hesitate to take upon his own shoulders the whole responsibility of military affairs. All the French settlements in India were promptly occupied. On the part of Bombay, the Mahatta war was conducted with promptness and dispatch. But Hastings amply avenged the capitulation of Wagon by the complete success of his own plan of operations. Colonel Goddard with a Bengal army marched across the breadth of the peninsula, from the valley of the Ganges to the western sea, and achieved almost without a blow the conquest of Guzerat. Captain Popham, with a small detachment, stormed the rock fortress of Gwalior, then deemed impregnable and the key of Central India, and by this feat held in check Sindia, the most formidable of the Mahatta chiefs. The bhonsla, or Malhatta raja of Nagpur, whose dominions bordered on Bengal, was won over by the diplomacy of an emissary of Hastings. But while these events were taking place, a new source of embarrassment had arisen at Calcutta. The supreme court, whether rightly or wrongly, assumed a jurisdiction of first instance over the entire province of Bengal. The English common law, with all the subtleties and rigours of that day, was arbitrarily extended to an alien system of society. *Zamindars*, or government tenants, were arrested on meagre process, the sanctity of the *andam*, or women's chamber, as dear to Hindus as to Mahomedans, was violated by the sheriff's office, the deepest feelings of the people and the entire fabric of revenue administration were alike disregarded. On this point the entire council acted in harmony. Hastings and Francis went joint-bail for imprisoned natives of distinction. At last, after the dispute between the judges and the executive threatened to become a trial of armed force, Hastings set it at rest by a characteristic stroke of policy. A new judicial office was created in the name of the Company, to which Sir Elijah Impey was appointed, though he never consented to draw the additional salary

offered to him. The understanding between Hastings and Francis, originating in this state of affairs, was for a short period extended to general policy. An agreement was come to by which Francis received patronage for his circle of friends, while Hastings was to be unimpeded in the control of foreign affairs. But a difference of interpretation arose. Hastings recorded in an official minute that he had found Francis's private and public conduct to be "void of truth and honour." They met as duellists. Francis fell wounded, and soon afterwards returned to England.

The Mahratta war was not yet terminated, but a far more formidable danger now threatened the English in India. The imprudent conduct of the Madras authorities had irritated beyond endurance the two greatest Mussulman powers in the peninsula, the nizâm of the Deccan and Hyder Ali, the nautika of Mysore, who began to negotiate an alliance with the Mahrattas. A second time the genius of Hastings saved the British empire in the east. On the arrival of the news that Hyder had descended from the highlands of Mysore, out to pieces the only British army in the field, and swept the Carnatic up to the gates of Madras, he at once adopted a policy of extraordinary boldness. He signed a blank treaty of peace with the Mahrattas, who were still in arms, reversed the action of the Madras Government towards the nizâm, and concentrated all the resources of Dergal against Hyder Ali. Sir Eyre Coote, a general well known in former Carnatic wars, was sent by sea to Madras with all the troops and treasure that could be got together, and a strong body of reinforcements subsequently marched southwards under General Leslie along the coast line of Orissa. The landing of Coote preserved Madras from destruction, though the war lasted through many campaigns and only terminated with the death of Hyder. Leslie's detachment was decimated by an epidemic of cholera (perhaps the first mention of this disease by name in Indian history), but the survivors penetrated to Madras, and not only held in check the nizâm and the nizâm, but also corroborated the lesson taught by Goddard—that the Company's sepoy could march anywhere, when boldly led. Hastings's personal task was to provide the ways and means for this exhausting war. A considerable economy was effected by a reform in the establishment for collecting the land tax. The Government monopolies of opium and salt were then for the first time placed upon a remunerative basis. But these reforms were of necessity slow in their beneficial operation. The pressing demands of the military chest had to be satisfied by loans, and in at least one case from the private purse of the governor-general. Ready cash could alone fill up the void, and it was to the hoards of native princes that Hastings's fertile mind at once turned. Choyte Sing, râjâ of Benares, the greatest of the vassal chiefs who had grown rich under the protection of the British rule, lay under the suspicion of disloyalty. The wrath of Oudh had fallen into arrears in the payment due for the maintenance of the Company's garrison posted in his dominions, and his administration was in great disorder. In his case the ancestral hoards were under the control of his mother, the begum of Oudh, into whose hands they had been allowed to pass at the time when Hastings was powerless in council. Hastings resolved to make a progress up country in order to arrange the affairs of both provinces, and bring back all the treasure that could be squeezed out of its holders by his personal intervention. When he reached Benares and presented his demands, the râjâ rose in insurrection, and the governor-general barely escaped with his life. But the faithful Popham rapidly rallied a force for his defence. The native soldiery were defeated again and again, Choyte Sing took to flight, and an augmented permanent tribute was imposed upon his successor. The Oudh business was

managed with less risk. The wari consented to everything demanded of him. The begum was charged with having abetted Choyte Sing in his rebellion, and after the severest pressure applied to herself and her attendant eunuchs, a fine of more than a million sterling was exacted from her. Hastings appears to have been not altogether satisfied with the incidents of this expedition, and to have anticipated the censure which it received in England. As a measure of precaution, he procured documentary evidence of the rebellious intentions of the râjâ and the begum, to the validity of which Impey obligingly lent his extrajudicial sanction.

The remainder of Hastings's term of office in India was passed in comparative tranquillity, both from internal opposition and foreign war. The centre of interest now shifts to the India House and to the British Parliament. The long struggle between the Company and the ministers of the crown for the supreme control of Indian affairs and the attendant patronage had reached its climax. The decisive success of Hastings's administration alone postponed the inevitable solution. His original term of five years would have expired in 1778, but it was annually prolonged by special Act of Parliament until his voluntary resignation. Though Hastings was thus irremovable, his policy did not escape censure. Ministers were naturally anxious to obtain the reversion to his vacant post, and Indian affairs formed at this time the hinge on which party politics turned. On one occasion Dundas carried a motion in the House of Commons censuring Hastings, and demanding his recall. The directors of the Company were disposed to act upon this resolution, but in the court of proprietors, with whom the decision ultimately lay, Hastings always possessed a sufficient majority. Fox's India Bill led to the downfall of the Coalition Ministry in 1783. The Act which Pitt successfully carried in the following year introduced a new constitution, in which Hastings felt that he had no place. In February 1785 he finally sailed from Calcutta, after a dignified ceremony of resignation, and amid enthusiastic farewells from all classes.

On his arrival in England, after a second absence of sixteen years, he was not displeased with the reception he met with at court and in the country. A pension was openly talked of as his due, while his own ambition pointed to some responsible office at home. Pitt had never taken a side against him, while Lord Chancellor Thurlow was his pronounced friend. But he was now destined to learn that his enemy Francis, whom he had discomfited in the council chamber at Calcutta, was more than his match in the parliamentary arena. Edmund Burke had taken the subject aces of India under the protection of his eloquence. Francis, who had been the early friend of Burke, supplied him with the personal animus against Hastings, and with the knowledge of details, which he might otherwise have lacked. The Whig party on this occasion unanimously followed Burke's lead. Dundas, Pitt's favourite subordinate, had already committed himself by his earlier resolution of censure, and Pitt was induced by motives which are still obscure to incline the ministerial majority to the same side. To meet the oratory of Burke and Sheridan and Fox, Hastings wrote an elaborate minute with which he wearied the ears of the House for two successive nights, and he subsidised a swarm of pamphleteers. The impeachment was decided upon in 1788, but the actual trial did not commence until 1789. For seven long years Hastings was upon his defence on the charge of "high crimes and misdemeanours." During his absence abroad he appears to have borne himself with characteristic dignity, such as is consistent with no other hypothesis than the consciousness of innocence. At last, in 1795, the House of Lords gave a verdict of not guilty on all the charges laid against him, and he left the bar at

which he had so frequently appealed, with his reputation clear, but ruined in fortune. However large the wealth he brought back from India, all was swallowed up in defraying the expenses of his trial. Continuing the line of conduct which in most other men would be called hypocrisy, he forwarded a petition to Pitt praying that he might be reimbursed his costs from the public funds. This petition, of course, was rejected. At last, when he was reduced to actual destitution, it was arranged that the East India Company should grant him an annuity of £4000 for a term of years, with £90,000 paid down in advance. This annuity expired before his death, and he was compelled to make more than one fresh appeal to the bounty of the Company, which was never withheld. Shortly before his death he had been able to satisfy the dream of childhood, by buying back the ancestral manor of Daylesford, where the remainder of his life was passed in honourable retirement. In 1813 he was called on to give evidence upon Indian affairs before the two Houses of Parliament, which received him with exceptional marks of respect. The university of Oxford conferred on him the honorary degree of D.C.L., and in the following year he was sworn of the Privy Council, and took a prominent part in the reception given to the duke of Wellington and the allied sovereigns. He died on the 22d of August 1818, in his 86th year, and lies buried behind the chancel of the parish church, which he had recently restored at his own charges.

In physical appearance, Hastings looked like a great man, and not like a bad man. The body was wholly subjected to the mind. A frame naturally slight had been further attenuated by rigorous habits of temperance, and thus rendered proof against the diseases of the tropics. Against his private character not even calumny has breathed a reproach. As brother, as husband, and as friend, his affections were as steadfast as they were warm. By the public he was always regarded as reserved, but within his own inner circle he gave and received perfect confidence. In his dealings, with money, he was characterized rather by liberality of expenditure than by carefulness of acquisition. A classical education and the instincts of family pride saved him from both the greed and the vulgar display which marked the typical "nabob," the self-made man of those days. He could support the position of a statesman, general, and of a country gentleman with equal credit. Concerning his second marriage, it suffices to say that the Baroness Imhoff was about forty years of age, with a family of grown-up children, when the complainant law of her native land allowed her to become Mrs. Hastings. She survived her husband, who seems to have cherished towards her to the last the sentiments of a lover. Her children he adopted as his own, and it was chiefly for her sake that he deemed the penance which was twice held out to him.

Hastings's public career will probably never cease to be a subject of controversy. It was his misfortune to be the scapegoat upon whose head Parliament laid the accumulated sins, real and imaginary, of the East India Company. If the acquisition of our Indian empire can be supported on ethical grounds, Hastings needs no defence. No one who reads his private correspondence will admit that even his least defensible acts were dictated by dishonourable motives. It is more pleasing to point out certain of his public measures upon which no difference of opinion can arise. He was the first to attempt to open a trade route with Thibet, and to organize a survey of Bengal and of the eastern seas. It was he who persuaded the *pandits* of Bengal to disclose the treasures of Sanskrit to European scholars. He founded the Madrasa or college for Mahomedan education at Calcutta, primarily out of his own funds, and he projected the foundation of an Indian

Institute in England. The Royal Asiatic Society was established under his auspices, though he yielded the post of president to Sir W. Jones. No Englishman ever understood the native character so well as Hastings, none ever devoted himself more heartily to the promotion of every scheme, great and small, that could advance the prosperity of India. Natives and Anglo-Indians alike venerate his name, the former as their first beneficent administrator, the latter as the most able and the most enlightened of their own class. If Clive's sword conquered the Indian empire, it was the brain of Hastings that planned the system of civil administration, and his genius that saved the empire in its darkest hour.

The bibliography dealing with Warren Hastings is not large. The histories of Mill and Thoinson both adopt a standpoint that is on the whole advisable. The *Memoirs*, by Glegg, in 8 vols. (London, 1841) are too tedious to be read at the present day. The review of *Lost Memoirs* by Macaulay, despite its exuberance of colour, its Whig partiality, and its proved inaccuracies, will not easily be superseded as the one standard authority. There is a recent *Biography* by Captain Trotter (1878), which interesting information, in correction or amplification of Macaulay, may be found in the *Memoirs of Francis, with Correspondence*, &c., by Palkes and H. Meivale (1867), and in the *Memoirs of Sir E. Impey* by his son (1846), who deposited his private MS. materials in the British Museum. In 1873 the British Museum also obtained by purchase from a Mrs. Kintell 268 vols. of papers relating to Hastings, chiefly letters between 1767 and 1818. These have been partly utilized by Mr. Beveridge in a series of articles contributed to the *Contemporary Review* for October 1877, April 1878, and April 1879. (J. S. CO.)

HASTINGS, FRANCIS RAWDON HASTINGS, FIRST MARQUESS OF (1754-1826), ranks among those governors-general of India who, completing the work of Clive and Warren Hastings, achieved the creation of the Indian empire of England. The services of Lord Hastings in this respect were special and important. He was both governor-general and commander-in-chief in India from 1813 till the end of 1822, during that period he carried two important wars, the Nepanese and the Marhatta, to a successful issue, while adding to the territories of the East India Company, he in several respects altered and improved their policy, and by the sagacity and at the same time the generosity of his own administration (in which he exhibited the true qualities of a Christian prince) he won reverence from the natives and left a great name in India.

Lord Hastings was in no way connected with Warren Hastings, his family name was Rawdon. His father, Sir John Rawdon of Moira in the county of Down, fourth baronet, was created Baron Rawdon of Moira, and afterwards Earl of Moira, in the Irish peerage. His mother was the Lady Elfrabeth Hastings, daughter of the ninth earl of Huntingdon. Both his father and mother appear to have been persons of considerable ability and high cultivation. Lord Rawdon, as he was then called, having gone at an early age to the university of Oxford, joined the army in his seventeenth year as ensign in the 15th foot. His life henceforth was entirely spent in the service of his country, and may naturally be divided into four periods — from 1773 to 1782 he was engaged with much distinction in the American war, from 1783 to 1813 he held various high appointments at home, and took an active part in the business of the House of Lords, from 1813 to 1823 was the period of his labours in India, after retiring from which, in the last years of his life (1824-1826), he was governor of Malta.

In America Lord Rawdon served at the battles of Bunker's Hill, Brooklyn, White Plains, Monmouth, and Camden, at the attacks on Forts Mifflin and Clinton, and at the siege of Charleston. In fact he was engaged in all the chief operations of the war. Perhaps his most notable achievements were the raising of a corps at Philadelphia, called the Irish Volunteers, who under him became famous for their fighting qualities, and the victory of Hob-

kut Hill, which, when in command of only a small force, he gained by superior military skill and determination against an American *corps d'armée*. In 1782 he was invalided. The vessel in which he returned to England was captured and carried into Brest. This occasioned the loss of his papers and personal records of the war which would doubtless have been interesting. He was speedily released, and on his arrival in England was much honoured by George III., who created him an English peer (Baron Rawdon) in March 1783.

In 1793 Lord Rawdon succeeded his father as earl of Moira. In 1794 he was sent with 10,000 men from Southampton to Ostend to reinforce the duke of York and the allies in Flanders. The march by which he effected a junction was considered extraordinary. In 1803 he was appointed commander-in-chief in Scotland, and in 1804 he married Flora Muir Campbell, countess of Loudon in her own right. He and Lady Loudon lived at Duddington House near Edinburgh, where they were very popular. The opposition coming into power in 1806, Lord Moira, who had always voted with them, received the place of master general of the ordnance. He was now enabled to carry a philanthropic measure, of which from his first entry into the House of Lords he had been a great promoter, namely, the Debtors and Creditor Bill for relief of poor debtors. Ireland was another subject to which he had given particular attention. In 1797 there was published a *Speech by Lord Moira on the Disaffected and Alarmng State of Ireland*. Lord Moira's sound judgment on public affairs, combined with his military reputation and the honourable uprightness of his character, won for him a high position among the statesmen of the day, and he gained an additional prestige from his intimate relations with the princes of Wales. On two occasions, in 1809 and again in 1812 after the assassination of Perceval, these were negotiations for placing him at the head of affairs. As a further mark of the regent's regard Lord Moira received the order of the Garter, and in the same year was appointed governor-general and commander-in-chief of India. He landed at Calcutta, and assumed office in succession to Lord Minto in October 1813. He was now fifty-nine years of age. One of the chief questions which awaited him was that of relations with the Goorkha state of Nepal. The Goorkhas, a brave and warlike little nation, failing to extend their conquests in the direction of China, had begun to encroach on territories held or protected by the East India Company, especially they had seized the districts of Bootwal and Seoiar, in the northern part of Oudh, and when called upon to relinquish these, they deliberately elected (April 1814) to go to war rather than do so. Lord Moira, having travelled through the northern provinces and fully studied the question, declared war against Nepal (November 1814). The enemy's frontier was 600 miles long, and Lord Moira, who directed the plan of the campaign, resolved to act offensively along the whole line. It was an anxious undertaking, because the native states of India were all watching the issue and waiting for any serious reverse to the English to join against them. At first all seemed to go badly, as the British officers too much despised the enemy, and the Sepoys were unaccustomed to mountain warfare, and thus alternate extremes of rashness and despondency were exhibited. But this rectified itself in time, especially through the achievements of General (afterwards Sir David) Ochterlony, who before the end of 1815 had taken all the Goorkha posts to the west, and early in 1816 was advancing victoriously within 60 miles of Katmandoo, the capital. The Goorkhas now made peace, they abandoned the disputed districts, ceded some territory to the English, and agreed to receive a British resident. Ever since they have faithfully kept these terms, the northern frontier of India

has been securely fixed, and the Goorkhas have entirely kept aloof from the machinations of disaffected native states. For his masterly conduct of these affairs Lord Moira was created Marquis of Hastings, in 1816.

He had now to deal with internal dangers. A treacherous combination of Mahatta powers was constantly threatening the continuance of British rule, under the guise of plausible assurances severally given by the peahwah, Stadia, Holkar, and other princes. At the same time the existence of the Pindharee state was not only dangerous to the English, as being a warlike power always ready to turn against them, but it was a scourge to India itself. In 1816, however, the Pindharees entered British territory in the Northern Circars, where they destroyed 339 villages. On this, permission was obtained to act for their suppression. Before the end of 1817 the preparations of Lord Hastings were completed, when the peahwah suddenly broke into war, and the British were opposed at once to the Mahatta and Pindharee powers, estimated at 200,000 men and 500 guns. "The whole was utterly shattered in a brief campaign of four months (1817-1818). The peahwah's dominion had been annexed, and those of Sindia, Holkar, and the rajah of Bera lay at the mercy of the governor-general, and were saved only by his exceeding and honourable moderation. There was at last, after sixty years from the battle of Plassey, no question of the supremacy of British power in India, now more perfectly established by the more effectively dominant than the old Aurungzebe."¹ The Pindharees had ceased to exist, and peace and security had been substituted for misery and terror.

"It is a proud phrase to use," said Lord Hastings,² "but it is a true one, that we have bestowed blessings upon millions. Nothing can be more delightful than the reports I receive of the sensibility exhibited by the inhabitants to this change in their circumstances. The smallest detachment of our troops cannot pass through that district without meeting everywhere eager and exulting gratulations, the tone of which proves them to come from glowing hearts. Multitudes of people have, even in this short interval, come from the hills and fastnesses in which they had sought refuge for years, and have reoccupied their ancient deserted villages. The ploughshare is again in every quarter turning up a soil which had for many seasons have been stunted, except by the hoofs of predatory cavalry."

While the natives of India appreciated the results of Lord Hastings's achievements, the court of directors grumbled at his having extended the British territory. They also disliked and opposed his measures for introducing education among the natives and his encouraging the freedom of the press. Posterity has, however, vindicated the policy of Lord Hastings in all respects. In 1819 he obtained the cession by purchase to the island of Singapore. In finance his administration was very successful, as notwithstanding the expenses of his war he showed an annual surplus of two millions sterling. He laboured much at law reform, and he succeeded in greatly raising the status and character of the civil service of India. Lord and Lady Hastings by their stately and yet genial manners, and by their warm encouragement of literature and science, gave a high tone to the society of Calcutta. And he was the first governor-general to exhibit a personal interest in the exertions of the missionaries. Brilliant and beneficent as his career had been, Lord Hastings did not escape, any more than Clive, Warren Hastings, or Lord Wellesley the assaults of unjust detraction. His last years of office were embittered by the discussions on a matter very notorious

¹ For the interesting details of this campaign, as well as of the war in Nepal, see Frazer's *History of the Political and Military Transactions in India, during the administration of the Marquis of Hastings*.

³ Reply to Address of Inhabitants of Calcutta, see *Anatic Journal*, February 1819.

at the time, namely, the affairs of the banking house of W. Palmer and Company. The whole affair was mixed up with manœuvres against Lord Hastings, especially charging him with having been actuated by favoritism towards one of the partners in the firm. From imputations which were inconsistent with his whole character he has subsequently been exonerated. But while smarting under them he tendered his resignation in 1821, though he did not leave India till January 1823. He was much exhausted by the arduous and almost incredible labours which for more than nine years he had sustained. Among his characteristics it is mentioned that "his ample fortune absolutely sank under the benevolence of his nature," and, so far from having enriched himself in the appointment of governor-general, he returned to England in circumstances which obliged him still to seek public employment. In 1824 he assumed the comparatively small post of governor of Malacca, in which island he introduced many reforms and endeared himself to the inhabitants. He died in 1826, leaving a request that his right hand should be cut off and preserved till the death of the marchioness of Hastings, and then interred in her coffin.

No "talk" of the mixture of Hastings has appeared, but a story of his first tour in India, written for his children, has been published, and affords interesting indications of his character. For further particulars of his career see the *Asiatic Journal* for November 1823, and the *Asiatic Biography and Outline* for 1828, and for details of his Indian administration see PEARCE's work, *et cetera*, Wilson's continuation of Millin's *History of India*, and other Indian histories. (A. GR.)

HAT, a covering for the head worn by both sexes, and distinguished from the cap or bonnet by the possession of a brim. The modern hat can be traced back to the *pelletrina* worn by the ancient Romans when on a journey, and hats with brims were also used, probably on like occasions, by the earliest Greeks. It was not till after the Norman conquest that the use of hats began in England. A "hatte of bever" about the middle of the 12th century was worn by some of the "nobles of the lande, mett at Clarendon," and Piersant describes hats and plumes which were worn at Edward's court in 1340, when the *Guise* order was instituted. In the 13th century the use of the *coronet* hat which distinguishes cardinals was sanctioned by Pope Innocent IV. The merchant in Chaucer's *Canterbury Tales* had

"On his heed a Pruncheun bever hat,"

and from that period onwards there is a frequent mention of "felt hattes," "beaver hattes," and other like names. Throughout mediæval times the wearing of a hat was regarded as a mark of rank and distinction. The caprices of fashion in hats during the reign of Elizabeth may be understood from an extract from Stubbs's *Anatomie of Dances*, published about 1585—

"Sometimes they use their shyns on the crowne peaking up like the spires or shyns of a temple, standing a quarter of a yard above the crowne of these heads, some more, some lesse, as pleases the fantasies of their inconsistent mindes. Other some be flat, and lowe on the crowne, like the battlements of a house. Another sort be like rounde crownes, sometime with one luse of brude, sometimes with another, now black, now white, now russet, now rufous, now green, now yellow, now this, now that, never content with one colour as fashion was due to us and."

During the reign of Charles I. the Puritans affected a steeple crown and broad-brimmed hat, while the Cavaliers adopted a lower crown and a broader brim ornamented with feathers. Still greater breadth of brim and a profusion of feathers were fashionable characteristics of the hats in the times of Charles II, and the gradual expansion of brim led to the device of looping or tying up that portion. Hence arose various fashionable "cocks" in hats, such as the "Monmouth cock" &c., and ultimately, by the looping up equally of three sides of the low-crowned hat, the cocked hat which prevailed throughout the 18th century was elaborated.

Since the beginning of the present century the cocked hat as an ordinary article of dress has disappeared. The Quaker hat, plain, low in crown, and broad in brim, which originated with the sect in the middle of the 17th century, is also now becoming uncommon. See *COSTUME*.

HAT MANUFACTURE—Until recent times hats were principally made by the process of felting, and as tradition ascribed the discovery of that very ancient operation to St. Clement, he was assumed as the patron saint of the craft, and the annual festival of the trade continues to be held on St. Clement's day, the 23d November. At the present day the trade is divided into two distinct classes. The first and most ancient is concerned with the manufacture of felt hats, and the second has to do with the recent, but now most extensive and important manufacture of silk or dress hats. In addition to these there is the equally important manufacture of straw or plaited hats, which does not fall within the scope of this article, and hats are occasionally manufactured of materials and by processes not included under any of these heads, but such manufactures do not take a large or permanent position in the industry.

Felt Hats—As now made, felt hats are of three different kinds, plain soft, plain hard, and "nappe'd" or "rufted" felts. There is a great range in the quality of felt hats, the finer and more expensive qualities being made entirely of fur, for commercial qualities a mixture of fur and Saxony wool is used, and for the lower kinds wool alone is employed. The processes and apparatus necessary for making hats of fur differ also from those required in the case of woollen bodies, and in large manufactories machinery is now generally employed for operations which at no distant date were entirely manual. In the smaller factories, and for special objects, the old hand processes are still in operation.

An outline of the operations by which the old beaver hat was and to some extent yet is made will give an idea of the manual processes in making a fur napped hat, and the apparatus and mechanical processes employed in making ordinary hard and soft felts will afterwards be noticed.

Hatters' fur consists principally of the skin of rabbits (technically called coney) and hares, with some proportion of nutria, musquash, and beaver's hair, and generally any parings and cuttings from furriers are also used. Furs intended for felting are deprived of their long coarse hairs, after which they are treated with a solution of nitrate of mercury, an operation called *carotting* or *searage*, whereby the felting properties of the fur are greatly increased. The fur is then cut by hand or machine from the skin, and in this state it is delivered to the hat maker. Rabbits' fur for hat making now comes in large quantities from the Australian colonies, and it is also largely collected in the United Kingdom and in northern Europe. A considerable trade in rabbit fur for hat-making is maintained between Great Britain and the United States.

The old process of making a beaver hat is as follows. The materials of a proper beaver consist, for the body or foundation, of rabbits' fur, and for the nap, of beaver fur, although the beaver is often replaced or supplanted by a more common fur. Such a hat may be regarded as the highest achievement of the hatter. In preparing the fur plate, the hatter weighs out a sufficient quantity

Fig 1

of rabbit fur for a single hat, which is spread out and combined by the operation of boiling. The fur or skin (A, B) is about 7 feet long, and it stretches a single coat of rabbit (D), which the workman vibrates by means of a wooden pin (E), furnished with a half knot at each end. Holding the bow in his left hand, and the pin in his right, he causes the vibrating string to come in contact with the heap of tangled fur, which does not cover a space greater than that

of the hand. At each vibration some of the filaments start up to the height of a few inches, and fall away from the mass, a little to the right of the bow, their excursions being restrained by a concave frame of wicker work called the basket. One half of the material is first opened on, and, by bowing and gathering, or a patting use of the basket, the stuff is loosely matted into a triangular figure, about 50 by 88 inches, called a bat. In this formation care is taken to work about two-thirds of the fur down towards what is intended for the brim, which, being effected, greater density is induced by gentle pressure with the basket. It is then covered with a wetish linen cloth, upon which is laid the hardening skin, a piece of dry half-tanned horse hide. On this the workman presses or rakes until the stuff adheres closely to the damp cloth, in which it is then doubled up, freely pressed with the hand, and laid aside. By this process, called busing, the bat has become compactly folded and thinned toward the sides and point. The other half of the fur is next subjected to precisely the same processes, after which a cone-shaped slip of stiff paper is laid on its surface, and the sides of the bat are folded over its edges to its form and size. It is then laid paper-side downward upon the first bat, which is now replaced on the hurdle, and its edges are transversely doubled over the introverted side-laps of the second bat, thus giving equal thickness to the whole body. In this condition it is reintroduced between folds of damp linen cloth, and again hardened, so as to unite the two halves, the knitting together of which is quickly effected. The paper is now withdrawn; and the body in the form of a large cone is removed to the plank or battery room.

The battery consists of an open iron boiler or kettle (A, fig. 2), filled with scalding hot water, with shelves, B, C, partly of mahogany and partly of lead, sloping down to it. Here the body is first dipped in the water, and the sides of the cone are gently pressed and dried, when it is unfolded, rolled gently with a pin tapering towards the ends, turned, and worked in every direction, to toughen and shrink it, and at the same time prevent adhesion of its sides. Stopping or thickening the thin spots which now appear, on looking through the body,

Fig. 2.

is carefully performed by dabbing on additional stuff in successive supplies from the hot liquor with a brush (frequently dipped into the kettle, until the body has been struck sufficiently about one-half) and thoroughly squeezed. When quite dry, the body is performed, with a brush dipped into the varnish of shellac, and rubbed into the body, the surface intended for the inside having much more laid on than the outer, while the brim is made to absorb many times the quantity applied to any other part.

On being again dried, the body is ready to be covered with a nap of beaver hair. For this, in inferior qualities, the hair of the otter, nutria, or other fine hair is sometimes substituted. The requisite quantity of one or other of these is taken and mixed with a proportion of cotton, and the whole is bowed up into a thin uniform lap. The cotton merely serves to give sufficient body to the material to enable the workman to handle the lap. The body of the hat being damp, the workman presses over it a covering of this lap, and by moistening and gentle patting with a brush the cut ends of the hair penetrate and fix themselves in the felt body. The hat is now put into a coarse hair cloth, dipped, and rolled in the hot liquor until the fur is quite worked in, the cotton being left on the surface loose and ready for removal. The blocking, drying, and finishing processes in the case of beaver hats are similar to those employed for ordinary felts, except that greater care and dexterity are required on the part of the workman, and further that the coarse hairs or kemps which may be in the fur are cut off by shaving the surface with a razor. The nap also must be laid in one direction, smoothed, and rendered glossy by repeated wringing, ironings, and brushings. As the hat so finished is very durable, and it is much more light, cool, and easy-fitting to the head than the silk hat which has now so largely succeeded it.

Till a comparatively recent period all attempts to apply machinery to the principal processes in felt hat-making resulted in failure. As is the case with many other labour-saving appliances of recent introduction, the first efficient machinery for felt hat-making was

devised in America, and from the United States the machine-making processes were introduced into England about the year 1858; and now in all large establishments machinery such as that alluded to below is employed. For the forming of hat bodies two kinds of machines are used, according as the material employed is fur or wool. In the case of fur, the essential portion of the apparatus used consists of a cone of copper of the size and form of the body or hat to be made, perforated all over with small holes. The cone is made to revolve on its axis slowly over an anvil under which there is a powerful fan, which maintains a strong inward draught of air through the holes in the cone. At the side of the cone, and with an opening towards it, is a trunk or box from which the fur to be made into a hat is thrown out by the rapid revolution of a brush or like cylinder, and as the cloud of separate hairs is expelled from the trunk, the current of air being sucked through the cone carries the fibres to it and causes them to cling closely to its sides. Thus a coating of loose fibres is accumulated on the copper cone, and these are kept in position only by the exhaust at work under it. When sufficient for a hat body has been deposited, a wet cloth is introduced to revolve on its axis slowly over an anvil under which there is removed for folting, while another copper cone is placed in position for continuing the work. The felting of fur bodies is principally done by hand-labour, although machinery has recently been introduced by which it is partly done. The hat or body of wool hats is prepared by first carding in a modified form of carding machine. The wool is divided into two separate alvers as delivered from the card, these are worked and pressed together, and a conical block of wood mounted and geared to revolve slowly with a reciprocating horizontal motion, so that there is a continual crossing and recrossing of the wool as the alver is wound around the block, and the diagonal arrangement of the fibres, the essential feature in the apparatus, as thereby the strength of the finished felt is made equal in every direction; and when strained in the blocking the texture yields in a uniform manner without rupture. The wool wound on the double block forms a cone, and the alvers, which are separated by cutting around the median or base line, and clipping each half off at its own end. Into each cone of wool or alver the "silvers" is now placed to prevent the inside from matting, but as the cones are folded in cloth, and the alvers are pressed over a plate through which steam is blown. When well moistened and heated, they are placed between boards, and subjected to a rubbing action sufficient to harden them, and to beat out the uneven strong planking or folting operations. The planking of wool hats is generally done by machine, in some cases a form of filling mill being used; but in all forms the agency is heat, moisture, pressure, rubbing, and tarring.

When by thorough felting the hat bodies of any kind have been reduced to dense leathery cones about one-half the size of the original bat, they are dried, and, if hard felts are to be made, the bodies are at this stage hardened or stiffened with a varnish of shellac. Next follows the operation of blocking, in which the felt for the first time assumes approximately the form it is ultimately to possess. For this purpose the conical body is softened in boiling water, and is forcibly drawn over a hat-shaped wooden block. A string is passed round where the hand is to be, and the brim is then flattened out from the string. Next follows the dyeing of the hat in a bath of suitable materials, according to the fashion required, and the dyeing with fine hats, each hat is separately dyed while on the block, but with commoner qualities it is the practice to dye before blocking. The finishing processes include shaying on a block, over which the crown of the brim receive accurately fitted aluminium hats, which pounding or pumicing, which consists of smoothing the whole surface with emery or glass paper while the hat is still stretched on the block. The trimmer finally blades the outer brim and inserts the lining, after which the brim may get more of a curl or turn over according to prevailing fashion. Machines of American invention for blocking and pumicing have to some extent been introduced.

Silk Hats.—The silk hat, which has now become co-extensive with civilization, is an article of recent introduction. It was known in Florence about a century ago; but its manufacture was not introduced into France till about 1825, and its development has taken place entirely since that period. A silk hat consists of a light stiff body covered with a plush of silk, the manufacture of which in a brilliant glossy condition is the most important element in the industry; and in that manufacture the French are without equals. Originally the bodies were made of felt and various other materials, but now calico is almost exclusively used.

The calico is first stiffened with a varnish of shellac, and then cut into pieces sufficient for crown, side, and brim. The side-piece is wound round a wooden hat block, and its edges are joined by hot tarring, and the crown-piece is put on and similarly attached to

the side. The brim, consisting of three thicknesses of calico connected together, is now slipped on and brought to its position on the head. The whole of the body, thus prepared, now receives a coat of size, and subsequently it is washed over, and thus it is ready for the operation of covering. In covering this hat, the under brim, generally of muslin, is first attached, then the upper brim, and lastly the crown and side sewn together are drawn over. All these by hot ironing and stretching are drawn smooth and tight, and the finish of the body softens with the heat, body and cover adhere all over to each other without wrinkle or pull. Dressing and polishing by means of damping, brushing, and ironing, come next, after which the hat is "waxed" in a revolving machine by the application of hair-oil and oil of sweet-almonds, which cleans the nap and gives it a smooth and glossy surface. The brim has only then to be bound, the linings inserted, and the brim finally curled, when the hat is ready for use.

In all kinds of hat making the French excel, and in such centres as Anduze, Lyons and Paris the trade is very extensive and important. In the United Kingdom the felt hat trade is principally centred at Denton and other localities in the neighbourhood of Manchester, and in America the States of New York and New Jersey enjoy the greatest part of the industry. The value of the hats annually exported from the United Kingdom somewhat exceeds £1,000,000 sterling. (I PA.)

HATFIELD, or BISHOP'S HATFIELD, a quiet, old-fashioned market-town of England, in the county of Hertford, is prettily situated on the side of a hill, 17½ miles N N W of London by railway. The church of St Etheldreda dates its foundation from Norman times, though only a small portion of the original building is now standing. Hatfield is the seat of a poor-law union embracing four parishes. The population of parish in 1871 was 3998. In the vicinity is Hatfield House, on the site of a palace of the bishops of Ely, which was erected about the beginning of the 12th century. In 1538 the manor was resigned to Henry VIII by Bishop Goodrich, in exchange for certain lands in Cambridgeshire, Essex, and Norfolk, and after that monarch the palace was successively the residence of Edward VI immediately before his accession, of Queen Elizabeth during the reign of her sister Mary, and of James I. The last named exchanged it in 1607 for Thosbalds, near Chessington, in the same county, an estate of Sir Robert Cecil, afterwards earl of Salisbury, in whose family Hatfield House has since remained. The west wing of the present mansion, built for Cecil in 1608-11, was destroyed by fire in November 1835, the dowager-marchioness of Salisbury perishing in the flames. The grounds surrounding the house are extensive and beautifully laid out.

HATHRAS, or HATHRAS, a town in the Aligarh district, North-Western Provinces, India, in 27° 35' 31" N lat., 78° 6' 9" E long. It is well built, with numerous brick and stone houses, and is a prosperous trading centre. At the end of last century it was held by the Jats, the Durrani, and the British in 1803. A municipal hall and school-house stand upon the brink of a new tank, and the town also contains a post-office and Government charitable dispensary. Since it came under British rule, Hathras has rapidly risen to commercial importance, and now ranks second to Cawnpore among the trading centres of the Doab. The exports include coarse sugar, grain of all sorts, oil seeds, cotton, and ghee, and the imports embrace iron, metal vessels, European and native cloth, drugs, spices, and miscellaneous wares. Population (1872), 23,589, comprising 21,121 Hindus and 2468 Mahomedans.

HATTINGEN, a town of Westphalia, Prussia, in the government district of Arnsberg and the circle of Bochum, is situated on the river Ruhr, about 21 miles N E of Düsseldorf. It is the seat of a commission of justice, and possesses a good school. The manufactures comprise cloth,

woollen and silk goods, tobacco, iron, and steel. In the town are large iron works, a brewery, and a brandy distillery. There are iron stone and coal mines in the neighbourhood, and the scanty remains of the Iseburg, demolished in 1236. Hattungen was one of the Hanse towns of the Middle Ages. Its population in 1875 was 6995.

HATTO I (c. 850-913), tenth archbishop of Mainz, was born of a Swabian family about the middle of the 9th century. Educated at the monastery of Ellwangen or at Fulda, he attracted the attention of the emperor Arnulf, who in 883 made him abbot of Bacharach, in 889 abbot of Ellwangen, and in 891 archbishop of Mainz. During his reign Hatto acquired much ecclesiastical as well as political power. He presided over the council at Tübingen or Teuver (895), at which the emperor and twenty six or twenty seven bishops attended, and was employed as ambassador to Charles the Simple and the king of Lorraine at their conference at Saint Goar in 899. Twice he accompanied Arnulf to Italy, in 894 and 896. On the death of Arnulf in 900, Hatto became regent and guardian of Louis, and in the contest with the dukes of Babenberg treacherously betrayed into the emperor's hands Count Adalbert, who was one of their partisans. Under Louis's successor, Conrad I, Hatto retained his influence, but he died in 913, two years after Conrad's accession. Another but less probable account has it that he was killed at the battle of Haresburg in 912. Hatto was a zealous churchman and a bold and energetic statesman. By his influence the crown and the church combined to check the growing power of the great nobles. In a letter to Pope John IX, still extant, he defends the German bishops from certain charges made to the pope. There is a tradition, due probably to his ambition and violence, that his corpse was seized by the devil and thrown into the crater of Mount Etna. The tradition of the Mouse Tower on the Rhine at Bingen is connected with another Hatto, also archbishop of Mainz (968-970).

HATVAN, a market-town in the county of Heves, Hungary, is situated on the left bank of the Zagyva, at the junction of the Pest-Miskolcz, Hatvan-Rutka, and Hatvan-Szolnok lines of railway, about 30 miles E N E of Budapest, 47° 40' N lat., 19° 41' E long. Hatvan possesses a handsome church and an elegant castle. There are two large cloth factories, and a court of assize is held there. Many of the inhabitants of the town and neighbourhood are employed in raising fruit and melons, in improving the breed of sheep and in tending large herds of horses, which graze wild on the spacious communal pasture-lands. Cattle fairs are frequently held in the town, and the trade in horses is considerable. In 1870 the population amounted to 4018, for the most part Magyars by nationality and Roman Catholics by creed.

As a fortified place Hatvan rose to some importance in the Middle Ages. In July 1695 a diet of Magyar nobles was held there. Subsequent to the catastrophe at Mohács (1526), Hatvan, along with many other Hungarian towns, fell into the hands of the Turks. After being besieged by the imperialists in 1694 and 1695, it was taken by them on the 2d September 1696. In 1873 it was almost completely destroyed by the Ottoman forces. On the 2d April 1849 the Austrians were defeated by the Hungarians in a sanguinary engagement near the town.

HATZFELD (Hungarian, Zombolya), a market-town in the county of Torontál, Hungary, on the Austrian state line of railway, about 22 miles W of Temesvár, 46° 48' N lat., 20° 44' E long. The most important buildings are the Roman Catholic church, the chateau of Count Ceskonicz, a district court house, and the usual Government offices. The communal lands are large and very productive, more especially in wheat, barley, oats, Indian corn, and rape seed. The rearing of horses is extensively carried on. In 1870 the population amounted to 7981, for the most part Germans by nationality and Roman Catholics by creed.

HAUCH, JOHANNES CARSTEN (1790-1872), Danish poet, was born of Danish parents residing at Fredensbald in Norway, on the 12th of May 1790. In 1802 he lost his mother, and in 1803 returned with his father to Denmark. In 1807 he fought as a volunteer against the English invasion. He entered the university of Copenhagen in 1808, and in 1821 took his doctor's degree. He became the friend and associate of Steffens and Oehlenschläger, warmly adopting the new views about poetry and philosophy. His first dramas, *The Journey to Grønland* and *The Power of Fancy*, appeared in 1816 and 1817, and were followed by *Flowera*, but these works attracted little or no attention. Hauch therefore gave up all hope of fame as a poet, and resigned himself entirely to the study of science, to pursue which he went abroad. At Nice he had an accident which obliged him to submit to the amputation of one foot. He returned to dramatic production, and published *The Hamadryad*, *Bayazet*, *Tiberius*, *Gregory VII.*, *The Death of Charles V.* (1831), and *The Steps of Maestricht* (1832). These plays were violently attacked by the best critical organs, and enjoyed no success. Hauch then turned to novel writing, and published in succession four romances—*Vidhelm Zeben*, 1834, *Guldsmagen*, 1836, *A Polish Family*, 1839, and *Children on the Rhine*, 1845. In 1842 he collected his shorter *Poems*. In 1846 he was appointed professor of the Scandinavian languages in Kiel, but returned to Copenhagen when the war broke out in 1848. About this time his dramatic talent was at its height, and he produced one admirable tragedy after another, among these may be mentioned *Svend Grathe*, 1841, *The Suters at Kunküllern*, 1849, *Marsh Stig*, 1850, *Ilonow Lost and Won*, 1851, and *Tycho Brahe's Youth*, 1852. From 1858 to 1860 Hauch was director of the Danish National Theatre, in which he produced three more tragedies—*The King's Favourite*, 1859, *Henry of Navarre*, 1863, and *Julian the Apostle*, 1868. In 1861 he published another collection of *Poems*, and in 1862 the historical epic of *Valdemar Atterdag*. From 1861, when he succeeded Oehlenschläger, to his death, he held the honorary post of professor of æsthetics at the university of Copenhagen. He died in Rome in 1872. Hauch was one of the most prolific of the Danish poets, and his writings are unequal in value. His lyrics and romances in verse are always fine in form and often strongly imaginative. In all his writings, but especially in his tragedies, he displays a strong bias in favour of the mystical and supernatural. Of his dramas *Marsh Stig* is perhaps the best, and of his novels *Vidhelm Zeben* is admired the most.

HAUFF, WILHELM (1802-1827), a popular German novelist, was born at Stuttgart, 29th November 1802. Having lost his father, who was a Government official, at the age of seven, he reared with his mother to Tübingen, where he frequented the *Schola anatolica*. In 1818 he was sent to the *Klosterschule* at Blaubeuren, and two years later he entered the seminary of Tübingen. After having completed, in 1824, his philosophical and theological studies and taken his degree, he acted for two years as private tutor, and assumed, in January 1827, the editorship of the *Morgenblatt*. In the following month he married, and led a happy and quiet life, which was ended by a fatal illness on 18th November of the same year. Hauff's literary activity is comprised within the short space of about two years. In his *Marchenalmachen* for 1826 he published the *Fairy Tales* he used to relate to his pupils during his tutorship. They were distinguished by an originality of conception, a playful though somewhat fantastic humour, and an elegance of style, not usually met with in similar productions. These fanciful tales founded his fame as a narrator, and form, together with his subsequent novels, several of which belong to the same species, the basis of his per-

manent reputation as an author. His next publication, *Mittheilungen aus den Memoiren des Satane*, "Extracts from the Memoirs of Satan" (3 vols 1826-27), was of a fragmentary kind, but gave additional proof of his talent as a humorist. In 1826 he wrote a novel—*Der Mann im Monde*, "The Man in the Moon"—with the intention of satirizing and parodying the sentimental sensualism of Clauven, but in the course of composition the projected parody became a regular imitation, and, as he issued the novel under the name of that romance, the latter brought an action against him for the abuse of his name, and gained his lawsuit. Hauff succeeded, however, in morally annihilating that mendacious narrator by his witty *Conto sopra schifo*, "Controversial Sermon" (1826). Animated by the genius of Sir Walter Scott, Hauff wrote a historical romance called *Lichtenstern* (1826), which illustrated the most interesting period in the history of Württemberg, and, being one of the first historical German novels, acquired, in spite of its weakness as a literary composition, great popularity throughout Germany. His fanciful work, *Phantasien im Breme Rathskeller* (1827), is pervaded, especially in the first portion of the book, by an exuberant spirit of conviviality, which exercises a cheering effect on the reader, but his most perfect fiction is in the *Bettler in vom Post-des-Arte*. Hauff's works have gone, collectively and separately, through many editions, and some of his shorter poems have become regular "Volkslieder."

HAUG, JOHANN CHRISTOPH FRIEDRICH (1761-1829), a German epigrammatist, was born March 19, 1761, at Niederstottingen in Württemberg, and received his early training from his father, who was afterwards professor and preacher at Stuttgart. From the gymnasium in this city Haug passed in 1776 to the Prince Charles academy, where he had Schüler as a fellow scholar, and, after finishing the philosophical and theological course, he devoted himself to the study of legal science with so much success that he attracted the attention of the duke. In 1784 he was appointed secretary of the private closet to his patron, in 1791 received the title of curial and palatine count, in 1794 became the duke's private secretary, and in 1817 was made *Hofrath* or audio councillor and librarian of the public library at Stuttgart. In 1827 he travelled through northern Germany, and on 30th January 1829 he died. Haug began his career as an author by publishing *Swangedichte von Friedrich Hephthalmon* (Frankfurt, 1791), the pseudonym Hephthalmon being a comic equivalent of his own name (*Auge*, the eye, equal to *Ophthalmos*), and therefore Haug equal to Ophthalmos).

Among his later works, which are so often characterized by a love of fun as by power of wit, it is enough to mention *Epigramme und vermischte Gedichte*, Berlin, 1806, *Hundert Epigramme auf Asie die Kiste und Zürich*, 1806, *Epigrammatische Späße*, 1807, *Zuschnitt dem Buchschmuck und locus gewohnt*, Stuttgart, n. d., *Magnische Lieder*, Brauns, 1820, *Panorama der Lieder und des Witzes*, Tübingen, 1820, and, perhaps more famous than any, *Zweihundert Epigramme auf Herrs Witz ungeschulte Kiste*, Stuttgart, 1824, new edition, Brauns, 1823. Along with Weisace, Haug published *Epigrammatische Anthologie*, Stuttgart, 1807-1809, 10 vols. A selection from his poems appeared at Hamburg, 1807, 2 vols.

HAUG, MAXIM (1827-1876), Orientalist, was born at Oudorf near Balingen, Württemberg, January 30, 1827. As a self-taught lad he became a pupil in the gymnasium at Stuttgart at a comparatively late age, and in 1848 he entered the university of Tübingen, where he devoted himself to the study of the Oriental languages, and especially of Sanskrit under Roth. He afterwards for some time attended the lectures of Ewald and Benfey in Göttingen, and finally "habilitated" as a privat-docent at Bonn. In 1866 he removed to Heidelberg as collaborator in the preparation of Bunsen's *Reisebericht*, and in 1869 he accepted an invitation to India, where he became superintendent of Sanskrit studies and professor of Sanskrit in Poona. There

his previous acquaintance with the Zend language and literature enabled him to associate with the Parsees on such terms as afforded the best opportunities for perfecting his knowledge in this department. The result of his researches was the volume of *Essays on the Sacred Language, Writings, and Religion of the Parsees* (Dombay, 1862). After a residence of six years in India, he was compelled by domestic circumstances to return to Wittenberg in 1865, from Stuttgart he was called to Munich as first professor ordinarius of Sanskrit and comparative grammar in 1868. He died at Ragatz in Switzerland on the 3d of June 1876.

Besides the *Essays on the Parsees*, of which a new edition, by West, greatly enriched on the posthumous papers of the author, appeared in 1878, Haupt published a number of works of considerable importances to the student of the literatures of ancient India and Persia. They include *Die Philologie der Brachmanen* (1861), *Die Sanskrit Sprache der reinen Keilschriftperiode* (1865), *Die fünf Uddes, edita, translated, and expounded* (1858-60), in addition with translation and explanation of *The Ataneya Brahman of the Rigveda* (1868), *A Lecture on an original speech of Bharata* (1865), *Ein alt Indisches Paktien Glossar* (1867), *Ueber den Charakter der Paktiensprache* (1866), *Das 18te Capitel des Wundschid* (1866), *Ueber den Avesta* (1870), *Die alt Indische Paktien Glossar* (1870), *Die alt Indische Paktien Glossar* (1870), *Die alt Indische Paktien Glossar* (1870).

HAUGE, HANS NIKSØY (1771-1824), founder of a religious sect within the Lutheran Church in Norway and Denmark, was born in the former country, in the parish of Thau, April 8, 1771. With the aid of various religious work, which he found in his father's house, he laboured to supplement the scanty education which he had received as a peasant's son. In his twenty-sixth year, believing him self divinely commissioned, he began to preach in his native parish and afterwards throughout Norway. In 1800 he passed to Denmark, where, as at home, he gained many followers and assistants, chiefly among the lower orders. Proceeding to Christiansand in 1801, Hauge set up a printing-press to disseminate his views more widely, but was almost immediately arrested for holding illegal religious meetings, and for insulting the regular clergy in his books, all of which were confiscated. After being in confinement for ten years, he was released in 1814 on payment of a fine, and retiring to an estate at Bredvill, near Christiansia, he died there, March 29, 1824. His adherents, called *Haugians* or *Lese* (i.e., Readers), are still to be found in the south of Norway. By his writing and preaching he unquestionably did much to revive the spiritual life of the northern Lutheran Church. Though he cannot be said to have rejected any article of the Lutheran creed, the peculiar emphasis which he laid upon the evangelical doctrines of faith and grace involved considerable antagonism to the rationalism or ascetical views commonly held by the established clergy.

Hauge's principal writings are *Forog til Afstemning om Guds Frelsen*, 1798, *Angivning til nogle ubelagte Syn og Dilemma*, 1798, *Forklaring over Loven og Evangeliet*, 1808. For an account of his life and doctrines, see Chr. Jung's *Hans Nielsen Hauge og hans Samtid*, Christiansia, 1875.

HAUPT, MORITZ or MORIZ (1808-1874), one of the principal representatives at once of classical and of vernacular philology in Germany, was born at Zittau, in Lusatia, July 27, 1808. His early education was mainly conducted by his father, Ernst Friedrich Haupt, burgomaster of Zittau, a man of good scholarly attainment, who used to take pleasure in tuning German hymns or Goethe's poems into Latin, and whose memoirs have been employed by Freytag in the 4th volume of his *Bielen aus der deutschen Vergangenheit*. From the Zittau gymnasium, where he spent the five years 1821-1826, partly under the tuition of Luedemann, Haupt removed to the university of Leipzig with the intention of prosecuting theology, but the natural bent of his mind and the influence of Professor G. Hermann soon turned all his energies in the direction of what were to be his life-studies. On the close of his university course

(1830) he returned to his father's house, and the next seven years were devoted to quiet work not only at Greek, Latin, and German, but at Old French, Provençal, and Bohemian. In 1834 he became acquainted with Endlicher, Karjany, and F. Wolf at Vienna, and formed with Lachmann at Berlin a friendship which had great effect on his intellectual development. In September 1837 he "habilitated" at Leipzig as privat dozent, and his first lectures, dealing with such diverse subjects as Catullus and the Nibelungenlied, indicated the twofold direction of his labours. A new chair of German language and literature being founded in his behalf, the new task he received in succession the title of professor extraordinarius (September 1841) and professor ordinarius (November 1843), and in 1842 he married Louise Hermann, the daughter of his master and colleague. But the peaceful and prosperous course opening out before him at the university of Leipzig was brought to a sudden close. Having taken part in 1849 with Otto John and Theodor Mommsen in a political agitation for the maintenance of the imperial constitution, Haupt was deprived of his professorship by a decree of the 22d April 1851. Two years later, however, he was called to succeed Lachmann at the university of Berlin, and at the same time the Berlin academy, which had made him a corresponding member in 1841, elected him as ordinary member. For one and twenty years he continued to hold a prominent place among the scholars of the Prussian capital, making his presence felt, not only by the prestige of his erudition and the clearness of his intellect, but by the timeliness of his energy and the ardent fearlessness of his temperament. His death, which took place with very little warning, February 5, 1874, was the result of heart disease.

Haupt's critical work is distinguished by a happy union of the most painstaking investigation with intrepidity of conjecture, and while in his lectures and addresses he was frequently excited away by the excitement of the moment, and made sharp and questionable attacks on his opponents, in his writings he exhibits great self-control. The results of many of his researches are altogether lost, because he could not be prevailed upon to publish what fell much short of his own high ideal of excellence. To the progress of classical scholarship he contributed by *Questiones Catullianae* (1837), *Observationes Criticae* (1841), and editions of Virgil's *Eclogues* and the *Comynae* of Gaius and Nemesius (1838), of Catullus, Tibullus, and Propertius (3d ed., 1868), of Horace (2d ed., 1871), and of Virgil (2d ed., 1878). As early as 1838 he had Hoffmann von Fallersleben started the *Allgemeine Blätter*, which in 1841 gave place to the *Zeitschrift für deutsche Alterthum*, of which he continued editor till his death. His translation von Aeneas *Zus* (1839) and his *Leider, Bickeln, und der arme Mensch* (1842), Rudolf von Jan's *Die Genien* (1840), and his *Die Genien* (1840), and his *Die Genien* (1840) are the principal German works which he edited. To form a collection of the French songs of the 18th century was one of his favourite schemes, but a little volume published since his death, *Fransösische Volkslieder* (1877), is the only monument of his labours in that direction. Three volumes of his *Opuscula* have appeared (Leipzig, 1875-1877). See Kirchhoff, "Gedächtnissrede," in *Abhandl. der Königl. Acad. der Wissenschaften zu Berlin*, 1876, and Otto Belger, *Moriz Haupt als Lehrer*, 1879.

HAUPTMANN, MORITZ (1792-1868), although a composer of ability, was of infinitely greater importance as a writer on the theory of music. He was born at Dresden, October 13, 1792, and studied music under Scholz, Lanke, Grosse, and Molnachi, the rival of Weber. Afterwards he completed his education as a violinist and composer under Spohr, and till 1820 held various appointments in private families, varying his musical occupations with mathematical and other studies bearing chiefly on acoustics and kindred subjects. For a time also Hauptmann was employed as an architect, but all other pursuits gave place to music, and a grand tragic opera, *Mathilde*, belongs to the period just referred to. In 1822 he entered the orchestra of Cossel under Spohr's direction, and it was then that he first taught composition and musical theory to such men as Ferdinand David, Burgmüller, Kiel, and others. His compositions at this

time chiefly consisted of motets, masses, cantatas, and songs. His opera *Mithilde* was performed at Cassel with great success. In 1842 Hauptmann obtained the position of cantor at the Thomas-school of Leipzig (long previously occupied by the great Johann Sebastian Bach) together with that of professor at the conservatoire, and it was in this capacity that his unique gift as a teacher developed itself and was acknowledged by a crowd of enthusiastic and more or less distinguished pupils. He died on January 3, 1868, and the universal regret felt at his death at Leipzig is said to have been all but equal to that caused by the loss of his friend Mendelssohn many years before. Hauptmann's compositions are marked by symmetry and perfection of workmanship rather than by spontaneous invention.

Amongst his vocal compositions—by far the most important portion of his work—may be mentioned two masses, choral songs for mixed voices (*Op. 39, 47*), and numerous part songs. The results of his scientific research were embodied in his book *Die Natur der Harmonik und des Melos* (1853), a standard work of the kind, in which a philosophic explanation of the forms of music is attempted.

HAUSER. See BASHAN.

HAUSER, KASPAR, a German youth whose life was remarkable from the circumstances of apparently inexplicable mystery in which it was involved. He appeared on May 20, 1828, in the streets of Nuremberg, dressed in the garb of a peasant, and with such a helpless and bewildered air that he attracted the attention of the passers-by. In his possession was found a letter purporting to be written by a poor labourer, stating that the boy was given into his custody on the 7th October 1812, and that according to agreement he had instructed him in reading, writing, and the Christian religion, but that up to the time fixed for relinquishing his custody he had kept him in close confinement. Along with this letter was enclosed another purporting to be written by the boy's mother, stating that he was born on the 30th April 1812, that his name was Kaspar, and that his father, formerly a cavalry officer in the 6th regiment at Nuremberg, was dead. The appearance, bearing, and professions of the youth corresponded closely with these credentials. He showed a repugnance to all nourishment except bread and water, was seemingly ignorant of outward objects, wrote his name as Kaspar Hauser, and said that he wished to be a cavalry officer like his father. For some time he was detained in prison at Nuremberg as a vagrant, but on July 18, 1828, he was delivered over to the care of Professor Daumer, who undertook to be his guardian and to take the charge of his education. On October 17, 1829, he was found to have received a wound in the forehead, which according to his own statement had been inflicted on him by a man with a blackened face. Having on this account been removed to the house of a magistrate and placed under close surveillance, he was visited by Earl Stanhope, who became so interested in his history that he sent him to Ansbach to be educated. After this he became clerk in the office of Feuerbach, president of the court of appeal, and his strange history was almost forgotten by the public when the interest in it was suddenly revived by his death on the 14th December 1833 from a deep wound on his left breast. He affirmed that the wound was inflicted by a stranger, but many believed it to be the work of his own hand, and that he did not intend it to be fatal, but only so severe as to give a sufficient colouring of truth to his story.

In 1830 a pamphlet was published at Berlin, entitled *Kaspar Hauser nicht unwahr scheinlich an den Tagen*, but the truthfulness of its statements was denied by Daumer, who published *Erzählungen über Kaspar Hauser* (Nuremberg, 1829), and *Erzählungen über Kaspar Hauser* (Frankfurt, 1869), as well as *Kaspar Hauser, sein Wesen, seine Unschuld, sein Verhängnis* (Regensburg, 1878), in answer to Meyer's *Authentische Mittheilungen über Kaspar Hauser* (Ansbach, 1872). Feuerbach awakened considerable psychological interest in

the case by his pamphlet *Kaspar Hauser, Beispiel eines Verbrochens am Sittlichen* (Ansbach, 1832), and Karl Stanhope also took part in the discussion by publishing *Materialien zur Geschichte K. Hausers* (Heidelberg, 1836). The theory of Drummer and Feuerbach was that the youth was the son of the grand duke Charles of Baden, and that he had been kidnapped by the countess of Hottelberg in order to secure the succession to the duchy of the grand-duke Charles Frederick, but this theory was set aside in 1876 by the publication in the *Augsburger Allgemeine Zeitung* the official record of the baptism, post mortem examination, and burial of the heir supposed to have been kidnapped. See *Kaspar Hauser und sein bairisches Fürstenthum* (Heidelberg, 1876).

HAUY, RENE JUST (1743-1822), an eminent French mineralogist, commonly styled the Abbé Haüy, from being an honorary canon of Notre Dame, was born at St Jut, in the department of Oise, February 28, 1743. His parents were in a humble rank of life, and were only enabled by the kindness of friends to educate their son. He was sent to Paris to the college of Navarre, and afterwards to that of Lemoine, where he finished his course amid incredible privations and difficulties. He escaped from these when, in 1764, he was himself appointed one of the teachers in the first of the above named colleges. He began to devote his leisure hours to the study of botany, but an accident directed his attention to another field in natural history. Happening to let fall a beautiful specimen of calcareous spar belonging to a friend, he discovered, by examining the fragments, the geometrical law of crystallization. By experimenting on a hexahedral crystal of this substance, he found he could be so dissected, by drawing it by planes parallel to certain edges, as to exhibit a rhombohedral nucleus, and, by extending his experiments, he farther showed that the same result could be obtained from mechanical division of every crystal of the same species. This led him to the theory that crystals are composed of what he called "integrant molecules," which he held had each the same shape as the respective nuclei got at by mechanical division. To obtain the different crystalline forms these molecules were supposed to be built up in layers round the nucleus, each layer diminishing regularly in the number of rows of molecules, and the rows at the same time diminishing in the number of molecules according to the nature of the crystal. A full account of his mathematical theory of this subject is given by Haüy in his *Traité de Minéralogie* (see CRYSTALLOGRAPHY). Daubenton and Laplace immediately recognized the scientific value of the discovery, which, when communicated to the Academy, secured for its author a place in that society. Besides the important services which he rendered to crystallography, Haüy also greatly increased our knowledge of pyro-electricity. He demonstrated by experiment in the case of tourmaline that the positive and negative charges of electricity at the respective ends of the crystal diminish rapidly as we approach the middle point, where they disappear. He showed also that each particle of a broken pyro-electric crystal itself exhibits polarity, and he was likewise the first to observe that, in all minerals, the pyro-electric state has an important connexion with the want of symmetry of the crystals. In tourmaline, for instance, he found the vitreous charge always at the summit with six, and the resinous at the summit with three faces (see ELECTRICITY). When the Revolution broke out, Haüy was thrown into prison, and his life was even in danger, when he was saved by the intercession of Geoffroy Saint-Hilaire. Under Napoleon he became professor of mineralogy at the museum of natural history. He also obtained other scientific preferment, of which he was deprived by the feeble Government of the Restoration, though his royalism had been a serious bar to his promotion under the empire. His latter days were consequently clouded by the poverty which had threatened to blight his early career. But the courage and high moral qualities which had helped him forward in his youth did

not desert him in his old age; and he lived cheerful and respected till his death, June 8, 1832.

The following are his principal works:—*Essai d'une Théorie sur la Structure des Cristaux*, 1784; *Exposition raisonnée de la Théorie de l'Électricité et du Magnétisme, d'après les Principes d'Atyimus*, 1787; *De la Structure considérée comme Corroderée, d'après les Mémoires*, 1793; *Exposition abrégée de la Théorie de la Structure des Cristaux*, 1793; *Extrait d'un Traité Élémentaire de Minéralogie*, 1797; *Traité de Minéralogie*, 1802, 4 vols., 2d ed.; *Traité Élémentaire de Physique*, 1808, 1806, 2 vols.; *Tableaux Comparatifs des Résultats de la Cristallisation, et de l'Analyse Chimique relativement à la Classification des Minéraux*; *Traité des Pierres Précieuses*, 1817; *Traité de Cristallographie*, 1822, 2 vols. He also contributed papers to various scientific journals, particularly the *Journal de Physique*, *Magasin Encyclopédique*, *Annales du Muséum d'Histoire Naturelle*, and *Journal des Mines*.

HAVANA, HAVANNAH, or HABANA, more fully San Cristóbal de la Havana, the capital of Cuba, and one of the principal seats of commerce in the New World, is situated on the northern coast of the island in 23° 9' 24" N. lat. and 82° 22' 35" W. long. From the sea it presents a picturesque appearance. The background is indeed tame; but the long lines of fortifications, the church-towers, and the shipping relieve the somewhat tawdry effect of the gaily coloured houses. Though the walls, completed in 1702, have been almost entirely demolished since 1863, it is still usual to speak of the intramural and the extramural city. The former, lying close to the harbour, has streets of the narrowest possible description consistent with the existence of wheel traffic. The latter has been laid out on a spacious plan, with wide thoroughfares frequently fringed with trees. Most of the houses are built of solid stone and have flat roofs, after the manner in vogue in southern Spain, and, as the erection of wooden buildings has been illegal since 1772, it is only in the suburban districts that they are at all common. The lavish use of white marble in the decoration both of shops and dwelling-houses is one of the peculiarities of the popular taste; and it is worthy of remark that, though the native quarries would supply what is wanted, the marble is brought from Genoa. Cafés, restaurants, clubs, and casinos are both exceedingly numerous and largely frequented, forming a good indication of that general absence of domestic life among the white population which surprises the European visitor. Havana is still, as of yore, a city of smells and noises. There is no satisfactory cleaning of the streets or draining of the sub-soil, and the harbour is visibly rendered foul by the impurities of the town. Victorias,—of which it is the Cuban boast that there are 6000,—volantes, and other vehicles are driven through the thoroughfares with the utmost recklessness; and tramways and railways in the American fashion contribute to the confusion.

The principal defences of Havana are the Castillo de la Punta, to the west of the harbour entrance, the Castillo del Morro and San Carlos de la Cabaña to the east, the Santo Domingo de Atrases, which lies at the head of the western arm of the bay and commands both the city and the neighbourhood, and the Castillo del Principe, situated on an eminence to the west, and forming the terminus of the great Paseo Militar. El Morro, as it is popularly called, was first erected in 1539, but additions have been frequently made. La Punta, a much smaller fort, is of the same period. The castle of Atrases dates from about 1763, when the Conde de Rieja was governor of the island. Cabaña, which alone has accommodation for 4000 men, fronts the bay for a distance of 800 yards, and is defended on the land side by three bastions. To the east there lies a smaller fort, No. 4, or San Diego, on a hill about 100 feet high.

Of the churches in the city, which number more than a score, the most noteworthy is the cathedral erected in 1724 by the Jesuits. Externally it is plain though asymmetrical; but within it has richly frescoed walls, a floor of variegated

marble, and costly altars. In the wall of the chancel, a second-rate medallion and a sorer inscription distinguish the tomb of Columbus, whose remains were removed thither in 1796. It is enough to mention the churches of San Juan de Dios, dating from 1673, Santa Catalina (1658), San Agustino (1608), and San Felipe, which possesses a large library. Of monasteries and nunneries there is of course no lack; and the same may be said of charitable institutions. The most important of the seven hospitals is the Real Casa de Beneficencia, founded about 1780, and containing an orphan asylum, a home for vagrants, a lunatic asylum, and an infirmary.

Besides the university established in 1728, the city possesses a theological seminary, a military school, and a school of art. The governor and the bishop have their respective palaces, the former a large yellow stone building in the Plaza de Armas; a large prison, erected in 1771, capable of receiving 500 inmates, and with barracks for a regiment, forms a striking object in the general view of the city; and among the other public buildings are the exchange (El Muelle), the custom-house (formerly the

church of San Francisco), and the manzanera or headquarters of the artillery. Of the theatres, which have still to compete with the bull-ring and the cock-pit, the most important is the Tacón, erected in 1838, and capable of accommodating about 3000 persons. The promenades, drives, and public gardens form a notable feature of Havana: it is sufficient to mention the Plaza de Armas, with a statue of Ferdinand VII.; the Prado or Paseo Isabel, a long and handsome boulevard laid out in the 18th century; the Campo del Marte or drill-park; the Parque Isabel, the Paseo Tacón, the botanical gardens, and the gardens of Los Molinos, the suburban residence of the captain-general. The palm-tree avenues of Los Molinos are unusually fine. Along the borders of the bay there are several fine embankments, of which the best is perhaps that called either the Salón O'Donnell or the Alameda de Paula. In the coral rock of the coast sea-baths have been excavated, so that the bathers may run no risk from the sharks; each apartment is about 12 feet square and 6 or 8 feet deep, and the water enters by two port-holes. The city is supplied with water from the river Chorrera by an aqueduct (Canal Isabel II.) constructed by Antocelli under Philip II., and

the number of fountains is considerable. The markets—of which the most noteworthy are the Mercado de Castaño, erected in 1836, and the Mercado de Tacón or Plaza de Vapor—are abundantly stocked with fruits and vegetables. Several of the suburban villages (*eg*, Chorrera, Guanabacón) are attractive places of resort.

The bay of Havana makes one of the finest harbours in the world, easy of access, spacious enough to contain about 1000 large vessels, deep enough to allow them to come close up to the wharves, and, except in the case of a hurricane, well protected on all sides. The entrance, encumbered by neither bar nor rock, is 980 feet wide and 4200 feet long. Within, the bay breaks up into three distinct arms, named respectively, Marmelejo or Regla Bay, Guasimacón Bay, and El Fondo or Bay of Atates. The wharves are well built, and a good floating dock maintained by a private company. On the left hand of the entrance stands a lofty lighthouse tower.

In 1835 1860 vessels entered with a burden of 680,644 tons, in 1875 2194 vessels with a burden of 921,632 tons, and in the first six months of 1878 741 vessels with a burden of 449,786 tons. The average number of vessels annually in the ten years from 1864 to 1873 was 1981 (771, 140,600 tons) and of this number 647 (294,378 tons) were American, 689 (190,281 tons) Spanish, 842 (131,321 tons) British, 55 (46,318 tons) French, 56 (16,300 tons) Norwegian, and 82 (31,693 tons) German.

In spite of high tariffs and civil wars, and the competition of Matanzas, Cardenas, Cienfuegos, and other Cuban ports opened to foreign trade in modern times, the commerce of Havana continues to increase. As indicated by the statistics just quoted, the chief foreign customers are Britain and United States. While the latter is gradually taking a greater proportion of the trade, the British interest is gradually diminishing. The two staple exports of sugar and tobacco were. While the average export of sugar for the last ten years of the century was only 177,396 boxes (31,199,200 lb), by 1855 it had reached 967,077 boxes (386,870,800 lb), and by 1878 145,601 boxes, 103,786 hogsheads, and 91,974 tons, or a grand total of nearly 408 millions of lb. In 1867 there were exported 7,716,492 cigars, valued at \$7,716,492, and the corresponding numbers for 1878 were 18,864,800 lb and 14,638 millions. Other exports of importance are rum, wax, and honey. The nature and quantities of the imports on an average of the ten years 1868 to 1877 are 285,302 quintals (100 lbs each) of jerked beef, 184,908 quintals of cod fish (81,678 from Europe, and 41,019 from United States), 359,298 barrels of flour, 627,786 quintals of rice (mainly from the East Indies), 143,095 quintals of lard (from the United States), 55,508 pipes of wine, 146,589 tons of coal, 344,095 jars of olive oil, and 99,887 quintals of castor oil.

The staple manufacturing industry of Havana is that of tobacco. Of the cigar factories there are a number which are regarded as of the first class. The Royal and Imperial Factory of La Hombres, which occupies a whole square, and is considered one of the great sights of the city, produces daily 2,636,000 cigarettes. Besides the making of boxes and barrels, and other articles necessarily involved in its sugar and tobacco trade, Havana also prescribes to some extent the building of carriages and ships, and the manufacture of iron and machinery, but the weight of taxation is too great to allow the development of any business requiring great capital. There were iron banks in the city in 1877, the most important being the Spanish Bank, through which all the Government paper is issued.

Havana has steam communication several times a week with New York, once a week with Baltimore, Philadelphia, and New Orleans, and about as frequently with several ports in England, Spain, and France. It is the terminus of a railway system which reaches Cardenas, Cienfuegos, Matanzas, Sagadahoc, &c., and short lines run out to the Bay of Havana and Matanzas. Telegraphic telegraphs to all parts of the island, and a submarine cable to Key West forms part of the line of communication between Aspinwall and New York.

The population of Havana and its suburbs was stated at 139,996 in 1817, at 196,994 in 1841, at 208,076 in 1868, and at 169,154 in 1871. Of this last number 108,764 were whites, 27,698 free negroes, mulattoes, &c., and 29,807 slaves. By 1878 the total had reached, it is said, 280,000. None of these statistics can be received with much confidence as to their accuracy. Among the white population the proportion of males to females is extraordinarily high, according to the official returns, there die annually 3822 white males to 1204 white females. The average rate of mortality is 27 per thousand annually. Foreigners are subject to yellow fever, especially from June to September.

Havana, originally founded by Diego Velasquez in 1515 on an unhealthy site near the present harbour, and the south coast, was removed to its actual position about 1519, and soon began to be

considered one of the most important places in the New World. In 1628 the buccannans laid the settlement in slavery, but it was soon after retaken by Dr. Soto, who built the fortress of La Punta. The residence of the captain-general was transferred to Havana from San Juan de Cuba in 1691, and in 1689, to protect the city, which had been plundered by the pirates, José de Soto in 1656 and the city, and by Drake in 1585, Philip II of Spain ordered the erection of the Piedad de la Punta and the castle of El Morro on Los Tres Reyes. In the course of the 17th century the port became the great rendezvous for the gold ships of Spain, and the commercial centre of the Spanish possessions in America. The English under Admiral Pocock and the duke of Albemarle captured Havana in 1762, but it was restored to the Spaniards on 10th Feb 1763, in exchange for the Florids. The *Guacá de la Florida*, the first paper published in Cuba, appeared in 1783. In 1771 the port, which had formerly been, like the rest of Cuba, monopolized by Seville and Cadix, was declared open to all nations in regard to certain articles of trade, and this liberty was extended in 1818 to all goods whatsoever. During the despotism paternal administration of Tocon many improvements were introduced at Havana, the railway from Havana to Guines was commenced in 1856, a ferry between the city and the suburb of Regla was set on foot in 1837, and night watchmen, a police force, and a fire brigade were established. The first line of steamships from Cadix to Havana dates from 1856. Like the rest of Cuba the city has frequently suffered severely from hurricanes, the most violent being those of 1768 (St Theresa's), 1810, and 1846.

See the works referred to under CUBA.

HAVELBERG, an ancient town of Brandenburg, Prussia, in the government district of Potsdam and the circle of Westphalia, is situated on the Havel, about 6½ miles from its junction with the Elbe. The town is separated from Glöden (6½ miles), on the Berlin and Hamburg Railway. The town is built partly on an island in the Havel and partly on hills on the right bank of the river, on one of which stands the fine cathedral. The two parts, which are connected by a bridge, were incorporated as one town in 1875. Havelberg is the seat of a commission of justice. The inhabitants are chiefly engaged in farming, tobacco and gun manufacturing, sugar-refining, and shipbuilding, and in the timber trade. Population in 1875, 6907.

Havelberg is believed to have been founded as early as 946, the bishop, however, generally resided at Platenburg or Wittstock, a few miles to the north. In 1548 the bishopric was reduced, and the cathedral passed to the Protestant Church and returned its endowments till the edict of 1610, by which all former ecclesiastical possessions were assumed by the crown. The final secularization was delayed till 1819. Havelberg was formerly a strong fortress, but in the Thirty Years' War it was taken from the Danes by the imperial troops in 1627. Recaptured by the Swedes in 1651, and again in 1636 and 1680, it was in 1687 retaken by the Saxons under Kützeng. It suffered severely from a conflagration in 1870.

HAVERLOCK, SIR HENRY (1795-1857), an eminent British soldier, was the second of four brothers (all of whom entered the army), and was born at Ford Hall, Bishop-Wearmouth, Sunderland, on the 5th of April 1795. His parents were William Haverlock, a wealthy shipbuilder in Sunderland, and Jane, daughter of John Carter, solicitor at Stockton-on-Tees. When about five years old, Henry accompanied his elder brother William to Mr Bradley's school at Swancombe, whence at the age of ten he removed for seven years to Charterhouse School. In accordance with the desire of his mother, who had died in 1811, he entered the Middle Temple in 1813, studying under Chitty the eminent special pleader. His legal studies having been abridged by a misunderstanding with his father, he in 1815 accepted a second lieutenancy in the Rifle Brigade (95th), procured for him by the interest of his brother William. During the following eight years of service in Britain he read extensively and acquired a good acquaintance with the theory of war. In 1823, having exchanged into the 21st and thence into the 13th Light Infantry, he followed his brothers William and Charles to India, first qualifying himself in Hindustani under Dr Ghalibut, a celebrated Orientalist. At the close of twenty-three years' service he was still a lieutenant, and it was not until 1838 that, after three years' adjutancy of his regiment, he became captain. Before this, however, he had held several staff

appointments, notably that of deputy assistant-adjutant-general of the forces in Burmah till the peace of Yandab, of which he, with Comden and Knox, procured the ratifications at Ava from the "Golden Feet," who bestowed on him the "gold leaf" insignia of Burmese nobility. His first command had been at a stockade capture in the war, and he was present also at the battles of Napadee, Patnagoe, and Pagan. He had also held during his lieutenant various interships and the adjutancy of the king's troops at Chinsurah. In 1828 he published at Serampore *Campaigns in Iva*, and in 1829 he married Hannah Shephard, daughter of Dr. Marshman, the eminent missionary. About the same time he became a Baptist, being baptized by Mr. John Meek at Serampore. During the first Afghan war he was present as aide-de-camp to Sir Willoughby Cotton at the capture of Ghazni, July 29, 1839, and at the occupation of Cabul. After a short absence in Bengal to secure the publication of his *Memoirs of the Afghan Campaign*, he returned to Cabul in charge of recruits, and became interpreter to General Elphinstone. In 1840, being attached to Sir Robert Sale's force, he took part in the Khairi Cabul fight, in the celebrated passage of the defiles of the Ghilzees (1841), and in the fighting from Tereen to Jellalabad. Here, after many months' siege, his column in the *seu en masse* defeated Akbar Khan, April 7, 1842. He was now made deputy adjutant-general of the infantry division in Cabul, and in September he assisted at Jagdulluk, at Tezen, and at the release of the British prisoners at Cabul, besides taking a prominent part at Isafik. Having obtained a regimental majority he next went through the Mahabata campaign as Persian interpreter to Sir Hugh (Viscount) Gough, and distinguished himself at Mahajuppur in 1843, and also in the Sikh campaign at Mudki, Ferozshah, and Sobson in 1845. For these services he was made deputy adjutant-general at Bombay. He exchanged from the 53d to the 89th, then as second major into the 53d at the beginning of 1849, and soon afterwards left for England, where he spent two years. In 1854 he became quartermaster-general, then full colonel, and lastly adjutant-general of the troops in India. In 1857 he was selected by Sir James Outram for the command of a division in the Pussian campaign, during which he was present at the actions of Mohmmallah and Ahwas. Peace with Persia set him free just as the mutiny broke out, and he was chosen to command a column "to quell disturbances in Allahabad, to support Lawrence at Lucknow and Wazirah, at Cawnpore, to disperse and utterly destroy all mutineers and insurgents." At Futtahghur, July 12th, at Long and Pandooctodee on the 16th, at Cawnpore on the 16th, at Onao on the 25th, at Bussutunge on the 29th and again on August 5th, at Boohiya on August 12th, and at Bithoor on the 16th, he defeated overwhelming forces. Twice he advanced for the relief of Lucknow, but twice prudence forbade a reckless exposure of troops wasted by battle and disease in the almost impenetrable task. Reinforcements arriving at last under Outram, he was enabled by the generosity of his superior officer to crown his successes on the 25th of September 1857 by the capture of Lucknow. There he died, November 24, 1857, of dysentery, brought on by the anxieties and fatigues connected with his victorious march, and with the subsequent blockade of the British troops. He lived long enough to receive the intelligence that he had been created KCB for the first three battles of the campaign, but of the major-generalship which was shortly afterwards conferred he never knew. On November 26, before tidings of his death had reached England, letters patent were directed to create him a baronet, and a pension of £1000 a year was voted at the assembling of parliament. The baronetcy was afterwards bestowed upon

his eldest son, while to his widow, by royal order, was given the rank to which she would have been entitled had her husband survived and been created a baronet. To both widow and son pensions of £1000 were awarded by parliament. See Marshman's *Life of Hawelock*, 1860.

HAVERCAMP, SIGMUND (1683-1742), classical editor and numismatist, was born at Utrecht in December 1683. After studying at the university of his native town and at Leyden, he entered the church, and became minister of Stadsaan-t Haringvliet, in the island of Overflakke. There he remained till 1721, when he succeeded Gronovius in the Greek chair at Leyden, becoming shortly afterwards professor of history and rhetoric also. He died at Leyden, April 23, 1742.

His editions of Latin and Greek authors are useful and learned compilations, rather than original critical commentaries, and bear frequent traces of the rapidity with which they were produced. They are the following—*Terentius*, 1713, *Lucianus*, 1725, *Josephus*, 1728, *Eutropius*, 1729, *Cicero*, 1738, *Sallust*, 1742, and *Cassius*, 1748. See Dübner's *Classica* under these names. His principal numismatic works are *Dissertationes de Alexandri Magni Numismate*, 1723, *Thesaurus Numismaticus*, 1734, *Unos et Eidos*, illustrated from *Medale* (in Dutch), 1738, *Nummophylacium regium Christiano*, 1742. He was also the author of *Sylloge Scriptum in quo de lingua Græca verba et recta Pronuntiatio commentariis et selectis, ante, 1740*, *De rebus in rebus, ante, 1738*, and *De rebus in Antiquitates Romanas*, 1740.

HAVERFORDWEST (in Welsh *Hwlfordwest*), the chief town of Pembrokeshire, a seaport, market town, palisamentary and municipal borough, and county by itself, is picturesquely situated on a hill overlooking the West Cleddau river, 8 miles NNE of Milford, and 276 miles WNW of London. The town is clean and well built, though somewhat irregular, owing to its position. Its principal buildings are the guildhall and the market-house, both modern, and the church of St. Mary, one of the finest churches in South Wales. The old church of St. Martin is close to the castle, of which, built on a rocky eminence overlooking the river, only a wall and the keep remain, the latter with considerable additions being till lately used as the county prison. It was built by Gilbert de Clare, first earl of Pembroke, and during the insurrection of Owen Glendower was defended for Henry IV against the French allies of the Welsh. In the civil wars of the 17th century it was held by the royalists. The castle was visited in 1188 by Gualdus Cambrensis and Archbishop Baldwin. Below the end of the Parade, a public walk overlooking the river, are the ruins of a priory of Black Canons of the order of St. Augustine, dedicated to St. Mary and St. Thomas. The priory from the 12th century it was endowed, though not founded by Robert de Hwlford, whose liberal grants were confirmed by Edward III. The old wall and fortifications that formerly surrounded the town have totally disappeared. On the north side of the river is the suburb of Pendeigat, containing the remains of an ancient mansion, formerly occupied by a family of that name. Haverfordwest is the seat of an assize court and quarter sessions, and with the contributory boroughs of Fishguard and Nisbeth returns one member to parliament. The river is navigable as high as the bridge for small craft. Timber, tea, and spirits are imported, and coal, cattle, butter, and grain are exported. In 1105, the Flemings, who had been driven from their own country by inundations, were settled in this locality by Henry I, and the Flemings who had served under Stephen afterwards increased the colony. Their influence is still to be traced in the non-use of the Welsh language among the townspeople, and in the peculiar shape of the cottages in the surrounding country. Population in 1871, 6323, area, 1430 acres.

HAVERHILL, a city in Essex county, Massachusetts, United States, is situated on the north bank of the Merrimack river, 18 miles from its mouth, and opposite the towns

of Bradford and Groveland, with which it is connected by two fine bridges. It has railway communication with Boston, which is 32 miles south, and with Portland, 78 miles north. The city contains a handsome soldiers' monument of white marble, erected in 1869, several public halls, including the city hall, the Freemasons' and the Oddfellows' halls, and a public library with 30,000 volumes. Havrehill derives its prosperity from the manufacture of boots and shoes, chiefly of the finer kinds, in which about 150 firms are engaged, employing from 6000 to 8000 hands, and turning out goods to the annual value of about £2,000,000. Besides these there are about forty manufacturers of different articles used in this trade, as heels, lasts, shoe-nails, &c. The other manufactures include hats, paper-boxes, and woollen goods. The first settlement at Havrehill was made in 1640, and for 70 years as a frontier town it suffered much from savage attacks. A fine granite and bronze monument has been recently erected to commemorate the heroism of the early settlers. Havrehill was incorporated in 1645, and received its city charter in 1870. The population in 1870 amounted to 13,092, of whom 2003 were foreigners. In 1879 the number was estimated at 15,000.

HAVRE, Le (originally HAVRE DE GRACE), a town of France, the second to Marseilles in importance as a seaport, capital of an arrondissement in the department of Seine-Inferieure, is situated on the north bank of the estuary of the Seine, 143 miles N.W. of Paris and 55 W. of Rouen by rail. The greater part of the town stands on a level plain, but from the heights on which Ingouville, since 1856 united to Havre, is situated, a charming and varied prospect is obtained. In the lower part of the town the streets run chiefly in straight lines, and they are grouped round the basins or docks, which communicate by lockgates and are placed so as to form a triangle entered from the Outer Port. The old fortifications surrounding the town were demolished in 1856, and it is now defended by forts erected on the heights of Ingouville and Sainte-Adresse. The principal street is the Rue de Paris, running from north to south in the centre of the town, and among the principal promenades may be mentioned the Boulevard de Strasbourg, the Place Louis XVI., and the Jetée du Nord, which terminates in a lighthouse. Havre possesses a tribunal of the first instance, a tribunal of commerce, an exchange and chamber of commerce, a chamber of agriculture, a hydrographic school, and a communal college. The principal buildings are the churches of Notre Dame and St Francois, the new Hôtel de Ville, the Musée, containing apartments for a library, and for art, antiquities, and natural history, and with statues in front of Bernardin de St Pierre and Casimir Delavigne, natives of Havre, by David Angers; the theatre, the clubhouse called the *Cercle du Commerce*, the new palace of justice, the marines arsenal, the town-house, the custom-house, and the Frascati bath-house. The docks are among the finest in the world, and consist of eight separate basins, which, with the late enlargement of the outer harbour, afford 150 acres of accommodation for vessels. The new entrance to the harbour has a width of 100 metres or 328 feet. Lines of rails have lately been laid along the docks.

As these have absorbed much of the space on the quays, lading is frequently a slow and tedious process, but the completion of the lately projected harbour will afford all the facilities necessary in this respect. The completion of the proposed canal between Havre and the Seine near Tancarville would be a great commercial benefit to the port whose prosperity has, notwithstanding its advantages as the port of Paris, and its unsurpassed facilities for dock accommodation, been much hampered by the system of centralization, which has both retarded improvements and led to the levying of exorbitant shipping rates. Partly

on this account, not only has France been unable to maintain the transit of goods for Belgium, Switzerland, and Germany, but even much of the traffic of its own northern and eastern provinces has been directed to Antwerp. The latter port is served by an abundant network of railroads and canals, while Havre has only one convenient railroad (that to Paris by Rouen); and the river Seine with its dangers and high tariff. The completion of the scheme for a railway over Montivilliers to Dieppe will afford partial remedy for this state of matters. In the extensive ship-building yards of Havre the finest vessels of France are built, and many are also built for other countries. The construction of two new dry-docks has lately been proposed, one of which is to afford accommodation for the largest Atlantic steamers. Havre is now fortified as a fleet station and harbour of war. The port has regular steam communication with London, Liverpool, Southampton, Dublin, Glasgow, Hull, Swansea, Bristol, Dunkirk, Brest, Cherbourg, Rotterdam, Hamburg, Copenhagen, St Petersburg, Constantinople, West Indies, San Francisco, Vancouver Island, and New York. The total number of vessels which entered

the port in 1878 was 6491 with a tonnage of 2,192,778, while 6453 cleared with a tonnage of 2,143,517. For the 5 years ending 1878 the average number of vessels that entered was 6041 with a tonnage of 1,841,265, the number that cleared 6006 with a tonnage of 1,815,189. The average annual value of exports and imports is about 2800 million francs. The trade of Havre with the United States is very large, and it has always retained its superiority in the importation of cotton, one-third of which, however, it imports from other countries than America. It is also the chief port for the exportation of French goods to the United States, and an important point of emigration. Besides cotton its principal imports are petroleum, coals, wheat, woolen, silk, flax, mohair and jute tissues, spices, sugar, coffee, hides, dyewoods, and building timber. The principal exports are various French manufactured cloths, leather, jewellery, agricultural and dairy produce, wine, brandy, and oil. Fishing is extensively prosecuted. Besides the various industries connected with shipbuilding, Havre possesses sugar-refining works, tobacco manufactories, iron foundries, salt works, breweries, vitriol works, and manufactures of *faisance*, lace, silk, and paper. It is also much frequented for sea-bathing. The population in 1872 was 85,538, and in 1876 it was 85,407.

HAYTI (OR SAN DOMINGO)

clergy of the other islands, the vapour of human sacrifices supposed to reside in the volcanic vents, and direct the action of subtle use in fact indicated the goals objects of peculiar terror. Human sacrifices were slain on several occasions, and vast offerings presented to the spirits supposed to preside over the volcanic eruptions, especially during the periods of actual eruptions. The requiem of these idolatry rites excited, and its little and bloody Grottoque and repulsive wooden figures, umbrellas, and the bones of chiefs were the objects of worship. Human sacrifices were offered whenever a temple was to be dedicated, or a chief was sick, or a war was to be undertaken, and these occasions were frequent. The unquenchable of the people with regard to future state was undefined, but fearful. The law is said to be expected to be slowly drawn by evil spirits, or to dwell with the gods in burning mountains. The several ideas, such as that of the halakama, the tiller of the ground, and the builder of canoes and houses, had each their presiding deities. Household gods were also kept, but the natives worshipped in their habitations. One meatful provision, however, had existed from time immemorial, and that was a sacred inclosure, places of refuge into which those who fled in time of war, or from any violent pursuit, might enter and be safe. To violate this sanctity was one of the greatest crimes of which a man could be guilty.¹

In the former state of society the habits of the people were extremely licentious, men were living with several wives, and women with several husbands. Female virtue was an unknown thing, and there is no native word for it. This state of things has, however, been greatly altered by the creations of the missionaries.

As regards cannibalism, it appears that the heart and liver of the human victims offered in the temples were eaten as a religious rite, and that the same parts of any prominent warrior slain in battle were devoured by the victor chiefs in the belief that they would thereby inherit the valour of the dead man. When, on the death of the great warrior Kamehameha I, the chiefs assembled to deliberate what should be done with his body, one suggested that they should eat it, but this did not find favour with the others. The Hawaiians are a good-natured, light-hearted, and pleasure-loving race. They have many games, and sports, and the women spend much time in making flower garlands. Both sexes are passionately fond of riding, almost every one being in possession of a horse. They delight to be in the water, and swim with remarkable skill and ease. In the exciting sport of sail swimming, which always astonishes strangers, they balance themselves whilst standing or sitting on a small board which is carried landwards on the curling crest of a great roller.

In spite of moral and material progress—better food, better clothing, improved dwellings, and many other advantages of civilisation—the natives dying out, and, indeed, is threatened with extinction in the course of a few years. Captain Cook estimated the number of natives at 400,000, in 1823 the American missionaries calculated them to be only 142,000, the census of 1832 showed the population to be 130,313, and the census of 1878 proved that the number of natives was no more than 44,088. To account for this it is said that the blood of the race has become poisoned by the introduction of foreign diseases. The women are much less numerous than the men, and the married ones have few children at the most, two out of three have none. Moreover the mothers appear to have little maternal instinct, and there is consequently a neglect of the offspring. Whilst the Hawaiians are decreasing, the Chinese are coming in large numbers, and threaten in time to take their place. To counteract this, as well as to supply the pressing need for labourers, the Government has considered many schemes for introducing other immigrants. Polynesians from other islands have been brought over, and a considerable number of Portuguese have come from Madeira.

The language is a branch of the widely-diffused Malayo-Polynesian tongue, and Hawaiians and New-Zealanders, although occupying the most remote regions north and south at which any of their race have been found, can understand each other without much difficulty. This language

is soft and harmonious, being highly vocalic in structure. The only consonants are *h, l, m, n, p, k*, which are gently aspirated, *h*, the five vowels, and the vocative *o*, make up all the letters in use. The letters *a* and *i* have been suppressed of late years in favour of *l* and *z*, so that, for example, *taro*, the famous name of the *Colocasia* plant, is now *kalo*. The language was not reduced to a written form until after the arrival of the missionaries.¹

In the days of idolatry the only dress worn by the men was a narrow strip of cloth wound round the loins and passed between the legs. Women wore a short petticoat made of *tapa* (cloth prepared from the inner bark of the paper mulberry), which reached from the waist to the knee. But now the common class of men wear a shirt and trousers, whilst the better class are attired in the European fashion. The women are clad universally in the *holooka*, a loose white or coloured garment with sleeves reaching from the neck to the feet. A coloured handkerchief is twisted round the head or a straw hat is worn. Both sexes delight in adorning themselves with garlands (*leis*) of flowers and necklaces of coloured seeds.

The natives derive their sustenance chiefly from pork and fish both fresh and dried, and from the *kalo* (*Colocasia esculenta*), the banana, sweet potato, yam, and other vegetables. The root of the *kalo* affords the national dish called *poi*, after having been baked and well beaten on a bond with a stone pestle it is made into a paste with water and then allowed to ferment for a few days, when it is fit to eat. There was formerly a particular breed of dog which, after being fed exclusively on *poi*, was considered a great delicacy. The filthy liquor called *awa* or *laua* is still relished by the natives, and though it is only allowed to be made under licence, it is often prepared clandestinely.

The native dwellings are constructed of wood, or more frequently of husk thatched with palm leaves, the sides and top. What little cooking is undertaken is done outside. The oven consists of a hole in the ground in which a fire is lighted and stones made hot, and the fire having been removed, the food is wrapped up in leaves and placed in the hole beside the hot stones and covered up until ready.

Leprosy is prevalent amongst the natives, and the Government has established a settlement on the island of Molokai where all persons found to be affected with this disease are kept entirely isolated from the healthy part of the community. The leprosy number about 800. The natives and Chinese of Lanai have been embroiled, chiefly by Americans, in the production of sugar, the soil and climate being well suited to the cane in those localities where the water supply is ample. There are between 80 and 90 sugar estates, and most are being planted. The principal difficulty is the want of labour. The average yield of sugar per acre is 2½ tons, whilst in some favoured spots as much as 7 tons has been obtained. In 1878 the exports of sugar amounted to 17,187 tons. Rice is also largely cultivated, 2445 tons having been exported in the same year. Coffee is produced only to a small extent. Arrow root is prepared from the root of the *Tacca pinnatifida*. The *kalo* plant (*Colocasia esculenta*) is extensively grown in wet places, and is at least a patch of *kalo* measuring 40 feet square yields sufficient food for a native for a whole year, a square mile of it would therefore support 17,000 persons. Maize and wheat are raised, and flour is manufactured. Pine apples, oranges, mangoes, citrons, pine apples, guavas, and many other fruits have been introduced, and flourish in gardens. A silky fibre called *pipe*, growing on the acorn of tree fern stems belonging to the genus *Cibotium*, is exported in large quantities to America, where it is used for stuffing cushions.

The owners of sheep are few, but they have large flocks, and the wool exported in 1878 amounted to 523,000 lb. Some districts are well suited for cattle raising. The wild cattle on the mountains—a very unimproved breed, descended from some left by Captain Vancouver—are shot or taken with the same for the price of their hides, which are exported in large quantities. In one island 11,000 were killed in a single year. The natives used to trap them by digging pits

¹ See Chamisso, *Ueber die Hawaiiische Sprache* (Lempe, 1857), and Andrews, *Gleaner of the Hawaiian Language* (Honolulu, 1851), and Dictionary (Honolulu, 1865).

who have established a board to superintend the affairs connected with this subject. Nearly every native can read and write. In 1878 there were 223 schools, attended by 3991 boys and 3000 girls. In the majority of these schools the instruction is communicated in Hawaiian, but in a considerable number of American establishments, and, as the people themselves desire it, that language is most, and more introduced.

Revenue and Customs.—The annual revenue of the Government amounts to about 600,000 dollars, derived chiefly from customs duties (234,000 dollars in 1878), taxes on real and personal property, and a poll tax. It does not equal the expenditure, and there is a funded debt of from 400,000 to 600,000 dollars. Accounts are kept in dollars, and the custom in circulation is that of American dollars.

The Capital.—Honolulu (population 14,114), the capital of the island group, stands on the S W coast of Oahu, in 157° 51' 48" W long and 21° 17' 56" N lat., at the mouth of the village of Nuuanu, which is just back between tall cliffs to the peaks about 3000 feet high in the great eastern range of mountains. It is the seat of the civil government and the residence of the king. Although consisting largely of one story wooden houses, mingled with grass huts half smothered by foliage, Honolulu is said to present to approaching vessels none of the appearance of a civilized place with its churches and public buildings than any other town in Polynesia. The suburbs, laid out in the American style, are in sight, and, truly. Water works supply the town from a neighbouring valley. Among the stone erections are the king's house, a hospital, a large hotel built by the Government, and the Government buildings, in which are a fine library of English books and a museum containing corals, shells, and other natural curiosities, as well as specimens of ancient weapons and other native articles. Amongst the brick buildings are large iron works, a brass foundry, an establishment for working up wood, and iron mills. All the necessary and most of the luxuries of civilized life can be obtained in Honolulu. There are several hotels for the accommodation of strangers, and numerous agencies of both British and American insurance offices, American and English medical men and lawyers have settled in the town, two weekly newspapers in English and two in the Hawaiian language are published. Honolulu has a good natural harbour, with wharves, a custom house, and warehouses. It is connected by regular lines of mail steamers with San Francisco, London, and New Zealand. There are also lines of steamers to Liverpool and Glasgow, New York and Boston, Bremen, China, and Peru. Small steamers ply between the islands. Business is almost entirely done by foreigners, and chiefly by Americans, British, Germans, and Chinese. The first are the most numerous, they are acquiring property rapidly, and some of them are wealthy. The foreigners are very sociable, and have established numerous clubs, benevolent societies, &c. American influence and customs are said to be dominant. In the neighbourhood of the town is a college, where for a small sum boys and girls receive a good English education.

The Separate Islands.—The following description of the separate islands begins with the largest and most easterly, giving the others in the order of their position.

Island	Length in Miles	Breadth in Miles	Estimated Area in Acres	Population 1878
Hawaii	100	80	2,600,000	17,034
Maua	12	20	100,000	12
Kahoolawe	12	6	30,000	60
Lanai	20	9	100,000	214
Molokai	35	7	200,000	2,681
Oahu	27	20	380,000	20,238
Kauai	30	28	850,000	6,634
Niihau	20	6	70,000	117
			4,000,000	87,985

In older English works Hawaii is called Owhyhee and Maui Mowee. The four neighbouring islets are named Nihoa, Kauai, Lanai, and Molokai.

HAWAII has an area nearly double that of all the other islands put together. In shape it is a rude triangle, with sides of 85, 76, and 65 geographical miles in length. Almost the whole of its surface is occupied by the gentle slopes of four volcanic mountains, Mauna Kea on the N, 18,806 feet in height (the highest peak in the Pacific Ocean), Mauna Loa on the S, 18,600 feet, Mauna Hualalai on the W, 8,375 feet, and Mauna Keolu on the N W, 8566 feet. The highest points of Mauna Kea are truncated cones with craters rising from plains of cinders and gravel, ashes and sand, but no modern streams of lava are visible, nor is there record of any eruption of this mountain since the year 1800. The west side is so gentle that the base of the mountain cones may be reached on horseback. On the windward side pyroclastic vegetation reaches as high as 12,000 feet, but the forest ceases at 8000 feet.

Mauna Loa is the most interesting mountain of the whole group from its being still an active volcano. The entire terminal crater,

8000 feet in diameter, is quite perfect, with nearly vertical walls from 500 to 600 feet high on the inner side, and the bottom between the numerous cones is usually covered with solid lava, from the fissures of which issue steam and sulphurous vapours, but which are not very dangerous, changing with every eruption. There is no eruption from Mauna Loa before 1832, when the lava flowed from the summit crater on several sides. In 1848 a vast flood of lava was discharged, which formed three streams 5 or 6 miles wide, and 400 to 2000 feet high. These lava flows, which in 1851, 1852, 1855, and 1860, but in none of these did the lava reach the very crest on the last occasion, when the eruption continued for two months, and a winding current 50 miles long, from 1 to 5 miles high, to break on the shore, consuming the forest of many trees and the destruction of much property. The lava crossed the Pacific to the California coast. Later in the same year, at a time when earthquakes were taking place on the coast of South America and the town of Iquique in Peru was destroyed, a great wave came across the Pacific, struck the Hawaiian Islands, and made itself felt in New Zealand. The last eruption took place in February 1877, when a stream of lava flowed for six hours.

Sixteen miles to the S E of Mauna Loa is a tall called Kilauea, with a crater which is the largest active one in the world. The earliest record of eruption was in 1789, and there was another in 1852. This volcano was first named Kilauea by the natives. In 1833, when Mr Ellis and a party of American missionaries visited it. At an elevation of 4400 feet above the sea they found in the midst of a plain an oval crater 9 miles in circumference with a rim 1000 feet deep, covered with the bottom of lava of liquid lava at one end and boiling. Around the edge of the rim the mud of this lava lake, 61 conical cinder-streets forth of lava or smoke and flame. A strong ledge round the middle of the crater, and 300 to 400 feet above the lake, indicated that the lava had risen to that height and had then run off by a subterranean channel to the sea, where some miles of coast had been filled up with liquid lava a few weeks previously. Since that time many eruptions have occurred, and the waters of both Kilauea and Kilauea, and have given vivid descriptions of the very grand and wonderful phenomena they witnessed. In 1840 the commander of the United States frigate Albatross, on a expedition to the work on the summit of Mauna Loa and made an accurate survey of the crater. In that year there was a great outburst from a crater 8 miles from the summit of Kilauea, when a stream of lava half a mile high and 40 miles long reached the sea.

On the whole summit of Hualalai, another of the four mountains of Hawaii, an occasional many jet craters from 500 to 500 feet deep and from 700 to 1000 feet in diameter, their solid walls being newly vertical. On the edge of one of the deepest craters there is a mound about 60 feet high, composed of drops of lava and fragments of all sizes, coloured yellow, orange, red, blue, and black. They seem to have been ejected in a rapid series, for they are slightly agglutinated together. In the centre of the crater is a lake 1000 feet in diameter and about 1800 feet deep. The inside of this hole is grooved horizontally, but otherwise smooth as if turned. More than 60 cones have been counted on the sides of Hualai. The last eruption took place in 1801, when a column of lava reached the coast, where it filled up a deep bay.

The lavas of Hawaii are distinguishable according to the aspect of their surfaces into three classes, the first is a smooth, shining, or velvety lava, and twisted in a manner that shows it was once a viscid fluid. This is the common form when the flow has passed over rocks or dry ground on a gentle slope. The cinders or scoriaceous lava is rough and irregular in appearance. This is found wherever the stream has passed through woods or has been impeded by inequalities of the ground, or where its heat has caused the explosion of caverns beneath the floor of older beds. The spongy lava, which is so much more common, is roughness and hardness is carefully avoided by all travellers. This form is thought to owe its origin to the fact that, just as the lava was granulating, impediments that stood in its course gave way, when the spongy mass called over and built up piles from which the liquid portion drained off. The natives are in the habit of making holes in the lava, and planting in them banana shoots or sweet-potato cuttings, and though the holes are simply filled with stones or fern leaves, the plants grow and in due time are productive of much fruit. The plain lying between the mountains of Hawaii is many square

1. Amongst the minor phenomena they speak of the delicate glassy lines called Pele's hair, by the Hawaiians, which are blown by the wind from the peaks and falling drops of liquid lava, and blown out at the edge. In the crevices of the crater there is the same time as the lava flows, and it is not without probability that a substance resembling Pele's hair is made from the ring of fresh cinders, by driving steam or air against the lava. These cinders are produced in great quantities, and much has been termed mineral or slag wool, it can be woven into sheets which are useful for coating stoves, &c., as the substance is a very hot conductor of heat.

HAWES, STEPHEN, a minor English poet of the 18th century. Neither the date of his birth nor that of his death has been ascertained, and all the known facts of his life may be stated in a few lines. He was probably a member of a Suffolkshire family, studied at Oxford, with what success we can only conjecture, travelled in England, Scotland, and France, and having acquired the reputation of a man of culture was appointed groom of the chamber to King Henry VII. He was still alive in January 1620-21, as appears by an entry, *Item to Mr Hawes for his play yf it was sryd*. Of the play thus mentioned nothing further is known. The writer's chief work was *The Historie of Grande Amour and La Bell Pucelle, called the Pastime of Pleasure, containing the Knowledge of the Seven Sciences and the Course of Man's Life*, a long allegorical poem in the style of Lydgate. Its general method may be guessed from such a heading as *How Science first sent him to Grames where he was eecyged by Dame Conyn wite*, and, though it must be confessed that portions of the poem are better both in matter and in workmanship than might be expected, it is now of interest almost exclusively because, in Warton's words, it is "almost the only effort of imagination and invention which had appeared in our poetry since Chaucer." Probably written about 1600, and first printed, it is said, by Wynkyn de Woide, it afterwards went through several editions (J. Wayland, 1554; Roland Tottel, 1555; J. Waley, 1559), a reprint of Tottel's was made for the Percy Society in 1912. Among the minor poems attributed to Hawes it is sufficient to mention his *Conversacion of Sweetes* and his *Joyful Medytacyon to all Englands of Kyng Henry the Eight*. The former, a dry didactic production, was printed by Wynkyn de Woide (1509?) and William Copland (1551). Of the latter the only copy preserved is among Bishop More's books in the public library of the university of Cambridge. Both were edited for the Abbotsford Club by David Laing (1854). For further details see Earle's edition of Warton's *History of English Poetry* (1871), and the Percy and Abbotsford societies.

HAWES, WILLIAM (1788-1846), an English musician of some merit, is remembered chiefly by the fact that through his instrumentality Weber's *Der Freischütz* was for the first time performed in England. This event took place July 24, 1824, and led eventually to Weber's removal to London. Hawes was born in London in 1788, and was for eight years (1798-1801) a chorister of the Chapel Royal, where he studied music chiefly under Dr Ayrton. He subsequently held various musical posts, being in 1817 appointed master of the children of the Chapel Royal. He also, in conjunction with Welsh, carried on the business of a music publisher, and was for many years musical director of the Lyceum Theatre, then devoted to English opera. He was in the last-named capacity that he introduced Weber's masterpiece, at first slightly curtailed, but soon afterwards in its entirety. Winter's *Intercepted Letter*, Mozart's *Cosi fan Tutti*, Werschnow's *Famyrre*, and other important works were also brought out under his auspices. Hawes also wrote or compiled the music for numerous pieces, none of which however has survived or deserves mention. Better were his glees and madrigals, of which he published several collections. He also superintended a new edition of the celebrated *Triumph of Oriana*. Hawes died February 18, 1846.

HAWFINCH, a bird so called from the belief that the fruit of the hawthorn (*Crataegus Oxyacantha*) forms its chief food, the *Lexia coelestis* of Linnaeus, and the *Coturnix vulgaris* of modern ornithologists, one of the largest of the Finch family (*Fringillidae*), and found over nearly the whole of Europe, in Africa north of the Atlas, and in Asia from Palestine to Japan. It was formerly

thought to be only an autumnal or winter-vistor to Britain, but later experience has proved that, though there may very likely be an immigration in the fall of the year, it breeds in nearly all the English counties to Yorkshire, and abundantly in those nearest to London. There seems also to be good reason for supposing that it is yearly extending its range in the British Islands. In coloration it bears some resemblance to a Chaffinch, but its much larger size and enormous beak make it easily recognizable, while on close inspection the singular bill hook form of some of its wing feathers will be found to be very remarkable. Though not uncommonly frequenting gardens and orchards, in which as its habit is, so as seldom to afford opportunities for observation. As the genus *Coturnix* is now commonly restricted, it includes but this single species,—the Japanese form, at one time regarded as distinct, being considered by the latest authorities to be inseparable. (A. N.)

HAWICK, a municipal and parliamentary borough of Roxburghshire in Scotland, 10 miles S W of Jedburgh, and 53 miles S S E of Edinburgh by rail, is situated on the south bank of the Teviot at its junction with the Slitting, a wild and irregular stream that flows through the town. A handsome bridge, spanning the Teviot, connects Hawick with the manufacturing village of Winton, which is practically a suburb. The town is fairly well built, the main street being broad and well paved. The ancient tower of the barons of Drumlanrig is now occupied as a inn, and many of the older houses testify by their massive proportions to the former dangers of Hawick's position as a border town. The town was the only building not burned down in 1570 by the earl of Sussex. The parish church of St Mary has succeeded one mentioned in the *Chronicle of Melross* as having been consecrated in 1214,—a fact which speaks for the antiquity of the town. Additional testimony is afforded by the Moatmill at one end of the town, an earthen mound of great antiquity, about 30 feet high. The present town-charter, granted in 1587 by a laird of Drumlanrig, was confirmed in 1645 by Queen Mary during a residence in the town. Hawick, with Winton, was in 1688 erected into a parliamentary burgh, uniting with Galashiels and Selkirk in sending a member to parliament. The municipal government is vested in a town council, consisting of a provost, four magistrates, and ten councillors. The exchange, built in 1865, contains a free public library. Hawick possesses a very complete system of underground drainage, in connexion with purification works,—this being the first experiment of the kind on a large scale in Scotland.

The manufactures of Hawick are mentioned in the burgh records so far back as 1640, but they must have been flourishing for some time before that, as the weavers already formed an important part of the population. The way in which they worked each for himself, executing his private orders, and it is not till the middle of the following century that a number of looms under one employer are heard of. Linen was at first the chief article of manufacture, but woollen plaidings were also made. Wool was also spun and sold to be manufactured elsewhere. A carpet factory was begun in 1752, and the manufacture of linen tapes or uikle dated a few years afterwards, but both industries became extinct towards the beginning of the present century. The manufacture of tweeds is the most important industry of Hawick. In this branch the annual turn-over is about £800,000, while in the whole woollen trade it is about £2,000,000. The manufacture of hosiery, to which the town owes so much of its prosperity, was introduced in 1771, when four looms, employing six men and five women, produced annually about 2400 pairs of coarse stockings. Hawick has gradually become the chief seat of this trade in Scotland. Some of the yarn spun at Hawick is sent

to England and to other parts of Scotland to be woven; while the merino yarn used for the finer goods is chiefly obtained from Plesley and Nottingham. Besides the staples, tweeds and hosiery, Hawick manufactures shawls, plaids, blankets, gloves, and leather. There are also an oil-works, for extracting oil from the soapy refuse of the fulling-mills, an iron-foundry, and a factory-engineering establishment. The population of the burgh in 1871 was 11,356; in 1879 it was estimated at about 15,000.

HAWK (Anglo-Saxon, *Ilafoc*), a word of somewhat indefinite meaning, being often used to signify all diurnal Birds-of-prey which are neither Vultures nor Eagles, and again more exclusively for those of the remainder which are not Buzzards, Falcons, Harriers, or Kites. Even with this restriction it is comprehensive enough, and will include more than a hundred species, which have been arrayed in genera varying in number from a dozen to above a score, according to the fancy of the systematizer. Speaking generally, Hawks may be characterized by possessing comparatively short wings and long legs, a bill which begins to decurve directly from the cere (or soft bare skin that covers its base), and has the cutting edges of its maxilla (or upper mandible) situated¹ but never notched. To these may be added as characters, structurally perhaps of less value, but in other respects quite as important, that the sexes differ very greatly in size, that in most species the males are yellow, deepening with age into orange or even red, and that the immature plumage is almost invariably more

European Sparrow-Hawk (Male and Female).

or less striped or mottled with heart-shaped spots beneath, while that of the adults is generally much barred, though the old males have in many instances the breast and belly quite free from markings. Nearly all are of small or moderate size—the largest among them being the Goshawk (vol. x. p. 788) and its immediate allies, and the male of the smallest, *Accipiter titius*, is not bigger than a Song-Thrush. They are all birds of great boldness in attacking a quarry, but if foiled in the first attempt they are apt to leave the pursuit. Thoroughly arboreal in their habits, they seek their prey, chiefly consisting of birds (though reptiles and small mammals are also taken), among trees or bushes, patiently waiting for a victim to show itself, and gliding upon it when it appears to be unwary with a rapid swoop, clutching it in their talons, and bearing it away to eat it in some convenient spot.

It is of course impossible here to enter into details of the numerous forms which, notwithstanding the limitation

¹ In one form, *Nisus*, which on that account has been generically separated, they are said to be perfectly straight.

above adopted, are to be called Hawks, or to describe the distinguishing characters, so far as any have been given, of the different groups or sections into which it has pleased systematic ornithologists to break them up, since hardly any two are agreed in the latter respect. There is at the outset a difference of opinion as to the scientific name which the largest and best known of these sections should bear—some authors terming it *Nisus*, and others, who seem to have the most justice on their side, *Accipiter*. In Europe there are two species—first, *A. nisus*, the common Sparrow-Hawk, which has a wide distribution from Ireland to Japan, extending also to northern India, Egypt, and Algeria, and secondly, *A. brevipes* (by some placed in the group *Micro-nisus* and by others called an *Astur*), which only appears in the south-east, and the adjoining parts of Asia Minor and Persia. In North America the place of the former is taken by two very distinct species, a small one, *A. fuscus*, usually known in Canada and the United States as the Sharp-shinned Hawk, and Stanley's or Cooper's Hawk, *A. cooperi* (by some placed in another genus, *Cooperastur*), which is larger and has not so northerly a range. In South America there are four or five more, including *A. tinus*, before mentioned as the smallest of all, while a species not much larger, *A. minulius*, together with several others of greater size, inhabit South Africa, Madagascar, and its neighbouring islands have three or four species sufficiently distinct, and India has *A. badius*. A good many more forms are found in South-eastern Asia, in the Indo-Malay Archipelago, and in Australia three or four species, of which *A. cirrhocephalus* most nearly represents the Sparrow-Hawk of Europe and Northern Asia, while *A. radiatus* and *A. approximans* shew some affinity to the Goshawks (*Astur*) with which they are often classed. The differences between all the forms above named and the much larger number here unnamed are such as can be only appreciated by the specialist, and could not possibly be pointed out within the limits of this article. It may be observed in conclusion that the so-called "Sparrow-Hawk" of New Zealand (*Hieracida*) does not belong to this group of birds at all, and by many authors has been deemed akin to the Falcons. For Hawking, see FALCONRY. (A. N.)

HAWKE, EDWARD HAWKE, BARON (1705–1781), an English admiral, was the son of a barrister and was born in 1705. He entered the navy at an early age, and in 1733 became commander of the "Wolf." In the engagement off Toulon in 1744, he broke from the line of battle in order to engage the "Poder," and although he succeeded in causing her to strike her colours, his breach of discipline was punished by dismissal from the service. He was, however, almost immediately restored by the king's commands, and in 1747 was promoted to the rank of rear-admiral of the white. In October of the same year he was sent in command of a squadron intended to intercept a fleet of merchant vessels bound for the West Indies under a convoy of nine men-of-war, and coming up with them on the 14th of the month near the isle of Aix, he succeeded after a severe struggle in capturing six of the men-of-war, but darkness coming on before the close of the contest the whole of the merchant vessels escaped. For his victory Hawke was created a knight companion of the Bath. In December of the same year he was chosen member of parliament for Bristol. In May 1748 he became vice-admiral of the blue, and in January 1755 admiral of the white. In the following year he succeeded Admiral Byng as commander of the fleet in the Mediterranean, but arrived too late to succour Minorca; and in none of the commands which he subsequently held did he have an opportunity of distinguishing himself till 1759, when he took charge of a squadron sent to cruise off Brest. On the morning of the 20th November he sighted the French fleet under Admiral Conflans off Belleisle, and

notwithstanding that the French, trusting to their knowledge of the rocks and shallows, retired towards the shore, he determined to engage them, which he did with such impetuosity that their fleet was only saved from total destruction by the approach of nightfall. As it was, more than half their vessels were either disabled, captured, or driven on shore. For this brilliant victory, gained in such circumstances of difficulty and danger, with the loss of only two vessels, Hawke received the thanks of the House of Commons and a pension of £2000 per annum. In 1765 he was appointed vice-admiral of Great Britain and first lord of the admiralty. In 1776 he was raised to the peerage by the title of Baron Hawke of Towton. He died at Shepperton, Middlesex, 17th October 1781.

HAWKESWORTH, JOHN (c. 1715-1773), an author of the last century, was born in London, according to one account in 1715, but according to another in 1719. He is said to have been apprenticed first to a clockmaker and afterwards to an attorney, but at any rate he was indebted for the education requisite for the prosecution of a literary career chiefly to his own perseverance. In 1744 he succeeded Dr Johnson as compiler of the parliamentary debates for the *Gentleman's Magazine*. Eight years later he started in company with Johnson, Bathurst, and Warton a periodical called the *Advertiser*. This journal had a great success, and ran to 140 numbers, of which 70 were from the pen of Hawkesworth himself. On account of what was regarded as its powerful defence of morality and religion, Hawkesworth was rewarded by the archbishop of Canterbury with the degree of LL.D. In 1761 he published a volume of fairy tales, and an edition of Swift's works and letters, with a life prefixed which Johnson has referred to in highly laudatory terms in his *Lives of the Poets*. This reputation he obtained by these and other works was such that he was commissioned by Captain Cook to edit his papers relative to his first voyage. The work appeared in 1773 in three volumes, and as a reward of his labours Hawkesworth received from the Government the sum of £2000. His descriptions of the manners and customs of the New World were, however, regarded by many critics as hostile to the interests of morality, and the severity of these strictures is said to have hastened his death, which took place November 17, 1773. He was buried at Bromley in Kent, where a monument has been erected to his memory. Hawkesworth was a close imitator of Johnson both in style and thought, but his independent literary talent is considerable.

HAWKINS, SIR JOHN (c. 1532-1595), was born in Plymouth about 1532, and was bred a sailor. Learning that negroes from the coast of Guinea were good merchandize for traffic in the West India, he made trial of this in three voyages, the first in 1562, the second in 1564. The third, made in company with young Drake in 1567, ended in disaster, the story of which is related by Hawkins himself. He was returned M.P. for Plymouth in 1572, and the next year he was made treasurer and comptroller of the navy. In the expedition against the Armada he was appointed vice admiral, hoisting his flag on board the "Victory," and for his services on that occasion he was afterwards knighted. His last expedition (1595) was undertaken, once more with Drake, mainly with a view to rescue his son Richard, who three years before had fallen into the hands of the Spaniards off the coast of Quito. It was unsuccessful, and, worn out with fatigue and broken-hearted, he died off Puerto Rico on the 12th of November 1595. Hawkins was the first to use chain pumps and fighting nettings for ships. Slow speaks of him as a very wise, vigilant, and true-hearted man. Along with Sir Francis Drake, he founded in 1588 the "Chest at Olatham," the forerunner of Greenwich Hospital, where

it is now preserved. A portrait of Hawkins once adorned the Armada tapestry in the House of Lords.

HAWKINS, SIR JOHN (1719-1780), will be permanently remembered as the author of an important work on the history of music. He was born March 30, 1719, in London, the son of an architect who destined his son for his own profession. Ultimately, however, Hawkins took to the law, devoting his leisure hours to his favourite study of music. A wealthy marriage in 1753 enabled him to indulge his passion for acquiring rare works of music, and he bought, for example, the collection formed by Di Pepuschi, and subsequently presented by Hawkins to the British Museum. It was on such materials that Hawkins founded his celebrated work on the *General History of the Sciences and Practice of Music*, in 5 vols. (republished in 2 vols., 1876). It was brought out in 1776, the same year which witnessed the appearance of the first volume of Dunsey's work on the same subject. The relative merits of the two works were eagerly discussed by contemporary critics. Burney no doubt is infinitely superior as a literary man, and his work accordingly comes much nearer the idea of a systematic treatise on the subject than Hawkins's, which is essentially a collection of rare and valuable pieces of music with a more or less continuous commentary. But by rescuing these from oblivion Hawkins has given a permanent value to his work. Of Hawkins's literary efforts apart from music it will be sufficient to mention his occasional contributions to the *Gentleman's Magazine*, his edition of the *Complete Angler*, and his biography of Dr Johnson, with whom he was intimately acquainted. He was one of the original members of the Ivy Lane Club, and ultimately became one of Dr Johnson's executors. If there were any doubt as to his intimacy with Johnson, it would be settled by the slighting way in which Boswell refers to him. Speaking of the Ivy Lane Club, he mentions amongst the members "Mr John Hawkins, an attorney," and adds the following footnote, which at the same time may serve as a summary of the remaining facts of Hawkins's life:—"He was for several years chairman of the Middlesex justices, and upon presenting an address to the king accepted the usual office of knighthood (1772). He is the author of a *History of Music* in five volumes in quarto. Dissuaduous attendance upon Johnson in his last illness, he obtained the office of one of his executors,—in consequence of which the booksellers of London employed him to publish an edition of Dr Johnson's works and to write his life." Sir John Hawkins died on the 21st of May 1780, and was buried in the cloisters of Westminster Abbey.

HAWKWOOD, SIR JOHN (ob. 1394), an English adventurer who attained great wealth and renown by his services as a condottiere in the Italian wars of the 14th century. According to the accepted if not the authenticated account of his life, he was the son of a tanner of Sible Hedingham in Essex, and was apprenticed to a tailor in London. Pressed into the army, he served with honour in France, obtained the favour of the Black Prince, and received knighthood from King Edward III. On the peace of Brétigny in 1360, he collected a band of men-at-arms, and moved southward to Italy, where we find him assisting the Pisans to defeat the Florentines in 1364. His services were sought in succession by Benabò Visconti, by the legate of Bologna, and by Pope Gregory XI. In 1375 the Florentines entered into an agreement with him, by which they were to pay him and his company of 130,000 gold florins in three months on condition that he undertook no engagement against them, and in the same year, the priors of the arts and the gonfalonier decided to give him a pension of 1200 florins per annum for as long as he should remain in Italy. His subsequent services to Florence as captain-

general of the city were numerous and important. Hawkwood married Donnana, an illegitimate daughter of Bonifacio Visconti, and one of his own daughters became the wife of the count of Fougère. His last years were spent in a villa in the neighbourhood of Florence. On his death in 1394 the republic gave him a public funeral of great magnificence and decreed the erection of a marble monument in the cathedral. This, however, was never executed, but Paolo Uccelli painted his portrait in terra verde on the inner facade of the building, where it still remains, though damaged by removal from the plaster to canvas. Richard II of England, probably at the instigation of Hawkwood's sons, who returned to their native country, requested the Florentines to let him remove the good knight's bones, and the Florentine Government signified its consent.

The fullest account of Sir John Hawkwood in English is in Nichol's *Elizabethan and English Historical Dictionary*, vol. vi. There is one of the last Johnson's *Antiquities of London* (published in *Illustrations*, 1803), and Fuller includes him in his *Worthies of England*. An elaborate life, by Mann is given in *Historical Review of the Reign of Henry V.* and Hawkwood is minutely described in *Armistice and the other Florentine chronicles*. The compact with the Florentines is printed in *Archæologia*, 1868.

HAWTHORN (Anglo-Saxon, *haga*, *hæg*, *hæy*, or *hege* *thorn*), *C. crataegus*, L., a genus of plants of the natural order *Rosaceæ* and sub order *Pinnæ*. The common hawthorn, termed also whitethorn, quickthorn, guilford, and May tree, May bush, or May (German, *Maydorn* and *Chridorn*, French, *Aubépine*), *C. oxyantha*, L., is a shrub or small tree having a smooth blackish bark, numerous branches, beset usually with thorns, which represent aborted twigs, alternate, long-stalked, obovate-wedge shaped, 3- or 5 lobed, incised or serrate smooth leaves, flowers sweet-scented, arranged in corymbs, and having adnate bracts, broad, white, pink, or scarlet petals, and 1 to 5 styles, and fruit or "haw" an oblong or nearly globular fleshy pome, commonly dark red, but occasionally yellow, black, or even greenish orange or dull white, and of 1 or 2 cells. The common hawthorn is a native of Europe as far north as 60° in Sweden, and of North Africa, Western Asia, and Siberia, and has been naturalized in North America and Australia. It thrives best in dry soils, and in height varies from 4 or 5 to 12, 13, or, in exceptional cases, as much as between 20 and 30 feet. There are several varieties of the plant. It may be propagated from seed or from cuttings. The seeds must be from ripe fruit, and if fresh gathered should be freed from pulp by maceration in water. They germinate only in the second year after sowing, in the course of their first year the seedlings attain a height of 6 to 12 inches. In England the hawthorn has been employed for enclosure of land since the Roman occupation, but for ordinary field hedges it is believed it was not generally in use till about the end of the 17th century. James I of Scotland, in his *Quair*, v. 14 (early 16th century), mentions the "hawthorn hedges knit" of Windsor Castle. The first hawthorn lodges in Scotland are said to have been planted by soldiers of Cromwell at Inch Buckling Brie in East Lothian, and Finlraig in Perthshire. On the planting and use of hawthorn fences, see *AGRICULTURE*, vol. i. pp. 296, 310. The wood of the hawthorn is white in colour, with a yellowish tinge. Fresh cut it weighs 68 lb 12 oz per cubic foot, and dry 67 lb 8 oz. It can seldom be obtained in large portions, and has the disadvantage of being apt to warp, its great hardness, however, renders it valuable for the manufacture of various articles, such as the cogs of mill-wheels, shafts and mallets, and handles of hammers. Both green and dry it forms excellent fuel. The bark possesses tanning properties, and in Scotland in past times yielded with ferrous sulphate a black dye for wool. The leaves are eaten by cattle, and have been employed as a substitute for tea.

Ands and deer feed upon the haws, which are used in the preparation of a fermented and highly intoxicating liquor, and for their astringency are sometimes resorted to in dysentery. The hawthorn serves as a stock for grafting other trees. As an ornamental feature in landscapes, it is worthy of notice, and the pleasing shelter it affords, and the beauty of its blossoms, have frequently been alluded to by poets. The custom of employing the flowering branches for decorative purposes on the first of May is of very early origin, but since the alteration in the calendar (see vol. iv p. 877) the tree is rarely seen in full bloom in England before the second week of that month. In Cornwall, however, in 1846, the flowers, though scarce, were gathered on the 18th April, and in the Scotch Highlands they may be seen as late as the middle of June. The hawthorn has been regarded as the emblem of hope, and its branches are stated to have been carried by the ancient Greeks in wedding processions, and to have been used by them to deck the altar of Hymen. The supposition that the tree was the source of Christ's crown of thorns gave rise doubtless to the tradition current among the French peasantry that it utters groans and cries on Good Friday, and probably also to the old popular superstition in Great Britain and Ireland that ill-luck attended the uprooting of hawthorn. Branches of the Glastenbury thorn, *C. oxyantha*, var. *pyracor*, which flowers both in December and in spring, were formerly highly valued in England, on account of the legend that the tree was originally the staff of Joseph of Arimathea (see *GLASTONBURY*, vol. x. pp. 674, 675). Sub species of *C. oxyantha* are *C. monogyne*, Jacquin, and *C. oxyanthoides*, Thuill. *C. pyracantha* and *C. Crus galli* are among the cultivated species of *C. crataegus*.

NATHANIEL HAWTHORNE

Copyright, 1876, by Richard Henry Stoddard

THE family name of Nathaniel Hawthorne was spelled Hathorne until it was changed by him in early manhood to its present form. The head of the American branch of the family, William Hathorne of Wilton, Wiltshire, England, emigrated with Winthrop and his company, and arrived at Salem Bay, Mass., June 12, 1830. He had grants of land at Dorchester, where he resided for upwards of six years, when he was persuaded to remove to Salem by the tender of further grants of land there, it being considered a public benefit that he should become an inhabitant of that town. He represented his fellow-townsmen in the legislature, and served them in a military capacity as a captain in the first regular troop organized in Salem, which he led to victory through an Indian campaign in Maine. Originally a determined "Separatist," and opposed to compulsion for conversion, he spiritualized himself when a magistrate by the active part which he took in the Quaker persecutions of the time (1657-62), going so far on one occasion as to order the whipping of Anne Coleman and four other Friends through Salem, Boston, and Dedham. He died, an old man, in the odour of sanctity, and left a good property to his son John, who inherited his father's capacity and intolerance, and was in turn a legislator, a magistrate, a soldier, and a bitter persecutor of witches. Before the death of Justice Hathorne in 1717, the destiny of the family suffered a sea-change, and they began to be noted as mariners. One of these seafaring Hathornes figured in the Revolution as a privateer, who had the good fortune to escape from a British prison-ship, and another, Captain Daniel Hathorne, has left his mark on early

American ballad hero. He too was a privateer, commander of the big "Fau American," which, cruising off the coast of Portugal, fell in with a British scow laden with troops for General Howe, which scow the bold Hathorne and his valiant crew at once engaged, and fought for over an hour, until the vanquished enemy was glad to cut the Yankee grapplings and quickly bear away. The last of the Hathornes with whom we are concerned was a son of this sturdy old privateer, Nathaniel Hawthorne. He was born in 1778, and about the beginning of the present century married Miss Elizabeth Clarke Manning, a daughter of Richard Manning of Salem, whose ancestors emigrated to America about fifty years after the arrival of William Hathorne. Young Nathaniel took his hereditary place before the mast, passed from the forecabin to the cabin, made voyages to the East and West Indies, Brazil, and Africa, and finally died of fever at Suva, in the spring of 1808. He was the father of three children, the second of whom, Nathaniel, was born at Salem, July 4, 1804.

After the death of his husband Mrs. Hathorne removed to the house of her father with his little family of children. Of the boyhood of Nathaniel no particulars have reached us, except that he was fond of taking long walks alone, and that he used to neglect his mother, that he would go to sea some time, and would never return. Among the books that he is known to have read as a child were Shakespeare, Milton, Pope, and Thomson, *The Castle of Indolence* being an especial favourite. In the autumn of 1818 his mother removed to Raymond, a town in Cumberland county, Maine, where his uncle, Richard Manning, had built a large and ambitious dwelling. Here the lad resumed his solitary walks, exchanging the narrow streets of Salem for the boundless, primeval wilderness, and its sluggish harbour for the fresh, bright waters of Sebago lake. He roamed the woods by day, with his gun and rod, and in the moon light nights of winter skated upon the lake alone till midnight. When he found himself away from home, and weary with his exercise, he took refuge in a log cabin where half a tree would be burning upon the hearth. He had by this time acquired a taste for writing, that showed itself in a little blank book, in which he jotted down his woodland adventures and feelings, and which was remarkable for minute observation and nice perception of nature.

After a year's residence at Raymond, Nathaniel returned to Salem in order to prepare for college. He amused himself by publishing a manuscript newspaper, which he called the *Spectator*, and which displayed considerable vivacity and talent. He speculated upon the profession that he would follow, with a sort of prophetic insight into his future. "I do not want to be a doctor and live by men's diseases," he wrote to his mother, "nor a minister to live by their sins, nor a lawyer and live by their quarrels. So I don't see that there is anything left for me but to be an author. How would you like some day to see a whole shelf full of books, written by your son, with 'Hawthorne's Works' printed on their backs?"

Nathaniel entered Bowdoin College, Brunswick, Maine, in the autumn of 1821, where he became acquainted with two students who were destined to distinction—Henry W. Longfellow and Franklin Pierce. He was an excellent classical scholar, his Latin compositions, even in his freshman year, being remarkable for their elegance, while his Greek (which was less) was good. He made graceful translations from the Roman poets, and wrote several English poems which were creditable to him. After his graduation three years later, he returned to Salem, and to a life of isolation. He devoted his mornings to study, his afternoons to writing, and his evenings to long walks along the rocky coast. He was scarcely known by sight to his townsmen, and he held so little communication with the

members of his own family that his meals were frequently left at his locked door. He wrote largely, but destroyed many of his manuscripts, his taste was so difficult to please. He thought well enough, however, of one of his compositions to print it anonymously in 1828. A crude melodramatic story, entitled *Fanshawe*, it was unworthy even of his immature powers, and should never have been rescued from the oblivion which speedily overtook it. The name of Nathaniel Hawthorne finally became known to his countrymen as a writer in *The Token*, a holiday annual which was commenced in 1828 by Mr. S. G. Goodrich (better known as "Peter Parley"), by whom it was conducted for fourteen years. This forgotten publication numbered among its contributors most of the prominent American writers of the time, none of whom appear to have added to their reputation in its pages, except the least popular of all—Hawthorne, who was for years the obscurest man of letters in America, though he gradually made admissions in a quiet way. His first public recognition came from England, where his genius was discovered in 1835 by the late Henry F. Chorley, one of the editors of the *Athenaeum*, in which he copied the see of Hawthorne's most characteristic papers from *The Token*. He had but little encouragement to continue in literature, for Mr. Goodrich was as much to a publisher as an author, that he paid him very little for his contributions, and still more wretchedly for his work upon an *American Magazine of Useful and Entertaining Knowledge*, which he persuaded him to edit. This author-publisher consented, however, at a later period (1837) to bring out a collection of Hawthorne's writings under the title of *Twice-told Tales*. A moderate edition was got rid of, but the great body of the reading public ignored the book altogether. It was generously reviewed in the *North American Review* by his college friend Longfellow, who said it came from the hand of a man of genius, and praised it for the exceeding beauty of its style, which was as clear as running water.

The want of pecuniary success which had so far attended his authorship left Hawthorne to accept a situation which was tendered him by Mr. George Bancroft, the historian, collector of the post of Boston under the Democratic rule of President Van Buren. He was appointed a weigher in the custom house at a salary of about \$1200 a year, and entered upon the duties of his office, which consisted for the most part in measuring coal, salt, and other bulky commodities. He sought for two years an alternate employment, but faithfully performed for two years, when he was succeeded through a change in the national administration. Master of himself once more, he returned to Salem, where he remained until the spring of 1841, when he wrote a collection of children's stories entitled *Grandfather's Chair*, and joined an industrial association at West Roxbury, Mass. Brook Farm, as it was called, was a social Utopia, composed of a number of advanced thinkers, whose object was so to distribute manual labour as to give its members time for intellectual culture. The scheme worked admirably—on paper, but it was suited neither to the temperaments nor the taste of Hawthorne, and after trying it patiently for nearly a year he returned to the everyday life of mankind.

One of Hawthorne's earliest admirers was Miss Sophia Peabody, a lady of Salem, whom he married in the summer of 1842. He made himself a new home in an old manse, at Concord, Mass., situated on historic ground, in sight of an old revolutionary battlefield, and devoted himself diligently to literature. He was known to the few by his *Twice-told Tales*, and to the many by his papers in the *Democratic Review*. He published in 1842 a second portion of *Grandfather's Chair*, and in 1845 a second volume of *Twice-told Tales*. He edited, during the latter year the

African Journals of Horatio Bridge, an officer of the navy, who had been in college with him, and in the following year he published in two volumes a collection of his later writings, under the title of *Mosses from an Old Manse*.

After a residence of nearly four years at Concord, Hawthorne returned to Salem, having been appointed surveyor of the custom-house of that port by a new Democratic administration. He filled the duties of this position until the incoming of the Whig administration again led to his retirement. He seems to have written little during his official term, but, as he had leisure enough and to spare, he read much, and pondered over subjects for future stories. His next work, *The Scarlet Letter*, which was begun after his removal from the custom-house, was published in 1850. If there had been any doubt of his genius before, it was settled for ever by this powerful romance.

Shortly after the publication of *The Scarlet Letter* Hawthorne removed from Salem to Lenox, Berkshire, Mass., where he wrote *The House of the Seven Gables* (1851) and *The Wonder-Book* (1851). From Lenox he removed to West Newton, near Boston, Mass., where he wrote *The Blithedale Romance* (1852) and *The Snow Image and other Twice-told Tales* (1852). In the spring of 1852 he removed back to Concord, where he purchased an old house which he called *The Wayside*, and where he wrote a *Life of Franklin Pierce* (1852) and *Tanglewood Tales* (1853). Mr. Pierce was the Democratic candidate for the presidency, and it was only at his urgent solicitation that Hawthorne consented to become his biographer. He declared that he would accept no office in case he was elected, lest it might compromise him, but his friends gave him such weighty reasons for reconsidering his decision that he accepted the consulate at Liverpool, which was understood to be one of the best gifts at the disposal of the president.

Hawthorne departed for Europe in the summer of 1853, and returned to the United States in the summer of 1850. Of the seven years which he passed in Europe five were spent in attending to the duties of his consulate at Liverpool, and in little journeys to Scotland, the Lakes, and also home, and the remaining two in France and Italy. They were quiet and uneventful, coloured by observation and reflection, as his note books show, but productive of only one elaborate work, *The Marble Faun*, which he sketched out during his residence in Italy, and rewrote and prepared for the press at Lexington, England, whence it was despatched to America and published in 1860.

Hawthorne took up his abode at *The Wayside*, not much richer than when he left it, and sat down at his desk once more with a heavy heart. He was surrounded by the throes of a great civil war, and the political party with which he had always acted was under a cloud. His friend ex-President Pierce was snubbed at a tutor, and when Hawthorne dedicated his next book to him—a volume of English impressions entitled *Our Old Home* (1863)—it was at the risk of his own popularity. His pen was soon to be laid aside for ever. For, with the exception of the unfinished story of *Septimus Felton*, which was published after his death by his daughter Una (1872), and the fragment of *The Dolliver Romance*, the beginning of which was published in the *Atlantic Monthly* in July 1864, he wrote no more. His health gradually declined, his hair grew white as snow, and the once stalwart figure that in early manhood flashed along the airy cliffs and glittering sands scattered idly on the little hill behind his house. In the beginning of April 1864 he made a short southern tour with his publisher Mr. William D. Ticknor, and was benefited by the change of scene until he reached Philadelphia, where he was shocked by the sudden death of Mr. Ticknor. He returned to *The Wayside*, and after a short season of rest joined his friend ex-President Pierce. He died at Plymouth, New Hamp-

shire, on May 19, 1864, and five days later was buried at Sleepy Hollow, a beautiful cemetery at Concord, where he used to walk under the pines when he was living at the Old Manse, and where his ashes moulded under a simple stone, inscribed with the single word "Hawthorne."

The writings of Hawthorne are marked by subtle imagination, curious power of analysis, and exquisite purity of diction. He studied exceptional developments of character, and was fond of exploring secret crypts of emotion. His shorter stories are remarkable for originality and suggestive ness, and his larger ones are as absolute creations as *Hamlet* or *Udine*. Lacking the accomplishment of verse, he was in the highest sense a poet. His work is pervaded by a womanly personality, and by an almost feminine delicacy and gentleness. He inherited the gravity of his Puritan ancestors without their superstition, and learned in his solitary meditations a knowledge of the night-side of life which would have filled them with suspicion. A profound anatomist of the heart, he was singularly free from morbidness, and in his darkest speculations concerning evil was robustly right-minded. He worshipped conscience with his intellectual as well as his moral nature, it is supreme in all he wrote. Besides these mental traits, he possessed the literary quality of style—a grace, a charm, a perfection of language which no other American writer has possessed in the same degree, and which places him among the great masters of English prose.

HAAKHAUSEN, AUGUST FRANZ LUDWIG MARIA VON (1792-1867), baron of Haxthausen-Abbenburg, was born on his father's estate near Paderborn in Westphalia, February 3, 1792. Educated at first at home, he proceeded in 1811 to the school of mining at Knausthal in the Harz, and after serving in the Hanoverian army in 1813-15, entered the university of Göttingen. On finishing his course there in 1818, he occupied himself with the management of his estates, and the study of the land laws and the legal rights of the peasantry. The result of his studies appeared in 1820 in *Die Agrarverfassung und ihre Konflikte*, a work which attracted much attention, and procured for him an official commission to investigate and report upon the land laws of the Prussian provinces with a view to a new code. After nine years spent in laborious collation, he published in 1829 an exhaustive treatise, *Die ländliche Verfassung in den Provinzen Ost- und West-Preussen*. In 1843-44, at the request of the emperor Nicholas, he undertook a similar labour for Russia. The fruits of his investigations in that country are contained in *Studien über die inneren Zustände, das Volksleben, und insbesondere die ländlichen Einrichtungen Russlands* (3 vols 1847-52), in *Die Kriegsmacht Russlands* (1852), and in *Die ländliche Verfassung Russlands* (1856). In 1836 he received the honorary title of privy state councillor, and afterwards of hiseditary chamberlain of the principality of Paderborn. In 1847-48 he sat as a member of the combined diet at Berlin, and afterwards of the first Prussian chamber. After travelling through a large part of Europe, Baron Haxthausen retired to his estate. He died at Hanover, January 1, 1867.

Besides the foregoing works, Haxthausen was the author of *The Alpine States*, a novel, and *Travels in the Alps of the Nations and Races before the Black Sea and the Caucasus*, in English, 1854. German, 1856, in 1861 he edited *Das Constitutionelle Prinzip*, a collection of political writings by various authors.

HAYDN, JOSEPH (1732-1809), one of the most celebrated composers of the 18th century, was born at Rohrau, a village in Lower Austria, March 31, 1732. Schindler relates that when Beethoven, not long before his death, received a picture of Haydn's birthplace, he exclaimed—"How wonderful that so great a man should have been born in a peasant's cottage." This cottage, which is still standing, had been built by Haydn's father, a worthy wheelwright, of whose twelve children the composer was

the soon! At an early age the child evinced so decided a talent for music that one Johann Matthias Frankh, a distant relation of the family, proposed to undertake his musical and general education, and for that purpose invited him to Haubing, a neighbouring town where Frankh kept a school. To Haubing accordingly young Haydn went in 1738, and there he received instruction in the elementary knowledge of his art, including a practical acquaintance with most instruments, at the hands of the musical schoolmaster. Having developed an agreeable soprano voice, young Haydn was by the intercession of the dean of Haubing promoted to a post amongst the choir boys of St Stephen's cathedral, Vienna, where he remained from 1740-50, doing duty in the church services, and at the same time enlarging his musical knowledge and experience. His artistic education was, however, all but exclusively practical, and it is said that he received only two theoretical lessons from Rauter the chapel-master. As a composer, therefore, Haydn was in every sense self taught. Of his zeal in acquiring information he was in the habit of talking with pride in later years, and several works of sacred music were the first fruit of his early studies. In 1749 or 1750 his beautiful boyish voice changed, and he lost his position accordingly. Being now thrown on his own resources, he had to undergo various forms of musical drudgery, such as giving lessons (at the moderate stipend of two florins per month) and even playing in the orchestra at dances and the like. His condition was somewhat improved by his acquaintance with Metastasio, the celebrated operatic poet, in fact the Scribo of the 18th century, who introduced him to Sofia Mattner, a Spaniard living in Vienna, whose daughter Haydn instructed for several years. It was through Metastasio also that Haydn came into contact with Porpora the composer, best known as the singing master of the great Faustini. For a considerable time Haydn remained in constant intercourse with him, acting as his accompanist, and occasionally it is said as his valet. In return he obtained a perfect acquaintance with Porpora's method, besides his knowledge of the Italian language, both invaluable to a composer in those days. The works of Emanuel Bach, son of the great Sebastian, at the same time became his model for chamber music. Fux's excellent work *Gradus ad Parnassum* was his guide in his studies of counterpoint. A mass in F, and a *Te Deum* *Unum Teufel*, both written in or about 1759, were Haydn's first important attempts at composition. The former is still in existence, but of the latter the libretto by Kutz only remains. It was produced early in 1762, and seems to have met with considerable success. Haydn's acquaintance with Gluck also dates from this period. An important event in Haydn's life was his acquaintance with Baron Füniberg, an accomplished amateur, for whose private concerts he wrote his first string quartet, a form of composition in which he gained some of his greatest and most permanent triumphs. It was in the key of B-flat, and was followed in rapid succession by seventeen other works of the same class, written during the years 1755 and 1756. To his new protector Haydn also owed his still more important acquaintance with Count Ferdinand Morzin. Count Morzin in 1759 appointed him conductor of his small but excellent band. The opportunities of hearing his own works performed by competent musicians Haydn did not neglect, and his first symphony in D belongs to the year 1759. Soon afterwards Count Morzin was compelled to dissolve his band, but Haydn's position was by this time sufficiently established, and very soon afterwards he found employment as second chapel-master to Prince Paul Esterházy, one of the richest Austrian nobles, whose love of art was as great as his wealth. The Esterházy family have been amongst the foremost patrons of music in Vienna from the days of Haydn to those of Beethoven and Schubert. Prince Paul

died in 1762, and left his title and fortune to his brother Nicholas, surnamed the Magnificent. He immediately enlarged his orchestra, and also increased the salaries of its members, including that of Haydn (from 400 to 600 forins), and on the death of his colleague Weisse, a scholarly but dry musician, appointed him first conductor. This position, or at least its title and emoluments, Haydn retained till his death, and his attachment to the Esterházy family remained unchanged by his subsequent fame and fortune. The events just referred to determined Haydn's career for the next twenty-eight years. During this period he was in the active service of his protector, residing at Esterházy, the splendid country seat of the family, described as a second Versailles, or in Vienna, conducting the orchestra of the prince, and writing for his concerts and theatre a number of works, including symphonies, cassations, quartets, sonatas, and numerous vocal compositions, including several operas, none of which, however, had any permanent success. Thus the opera *La vera Costanza*, written for the court theatre of Vienna in 1776, was withdrawn by the composer owing to intrigues against him, it is said, and we are not told that it met with a much better fate on its revival fourteen years later. Another dramatic work, *L'isola disabitata* (1779), procured for the composer the membership of the Accademia Filarmonica at Modena, and a gold snuff-box from the king of Spain. But with its companions it has not occupied oblivion. The truth is that Haydn was without the true dramatic spirit, and of this he was himself well aware. According to his own confession his operas were fitted only for the small stage at Esterházy, in a large theatre, and before a miscellaneous audience, they lost their effect. The scores of most of the operas are preserved in the archives of Eisenstadt, another seat of the Esterházy family. Of his life during this period little need be said. It was eventless and to a certain extent monotonous, but free from care and exclusively devoted to art. His own words, quoted by Herr Fohl, sum up all that it is necessary to relate: "My prince was always satisfied with my work, I not only had the encouragement of constant approval, but as conductor of an orchestra I could make experiments, observe what produced an effect and what weakened it, and was thus in a position to improve, alter, make additions or omissions, and be as bold as I pleased. I was cut off from the world, there was no one to confuse or torment me, and I was forced to become original." The only person that could have wished to "confuse or torment" the hapless composer was fortunately kept at distance by the strict order of the prince's household, that none of his musicians was to be accompanied by his wife. Haydn at an early age became attached to the daughter of a housemaid, Kellor by name, and after her death was persuaded to marry her sister, three years older than himself. The marriage was an unhappy one, and the pair separated soon after their union, Haydn's inflammable heart subsequently causing him more or less serious trouble on more than one occasion. In the meantime the composer's fame had begun to spread from an early period of his career. As early as 1768 a journal speaks of him as the "favourite of the nation," and foreign counts were not slow in acknowledging his merits. Thus one of his works, *The Seven Words of our Saviour on the Cross*, a series of orchestral interludes for the church service on Good Friday, was written by special invitation for the cathedral of Cadix. In Fux his works were performed with immense success at the Concert Spirituel, and a single English firm bought the copyright of no less than 129 of his works, including 82 symphonies. The appreciation of Haydn's work in England led to important results in his latter years. Several pressing invitations to visit that country had been declined by the composer on account

of his services being required at Estérel. But when in 1790 Prince Nicholas died, and his successor dissolved the orchestra, allowing Haydn a considerable pension, the latter was at last at liberty to accept a more than sufficient offer from Salomon, the violinist and entrepreneur, in whose company he staid for London, where Salomon occupied a leading position in the musical world. They left Vienna in December 1790, and travelled by way of Bonn, where Salomon had been born. There, accordingly, a halt was made, and Haydn was received by the elector with every honour due to his fame. The amusing description of a dinner given during his stay at Bonn may be read in Haydn's biography of Beethoven, who at that time was a member of the electoral chapel, and not unlikely made on this occasion Haydn's acquaintance. On the latter's return journey the young man submitted a cantata to the celebrated composer, whom he soon afterwards followed to Vienna to become his pupil. It is well known that the relations between the great master and his greater pupil were not altogether what might have been desired. Beethoven's claims as of too individual a type to bear the impress of a native so different as Haydn's, and the latter may not always have taken sufficient trouble to enter into the ways of his valiant pupil. Certain it is that, at one time of his career, Beethoven delighted in speaking slightly of "Papa Haydn," and, for instance, refused to call himself Haydn's pupil, because, as he bluntly said, he never learnt anything under his tutor. He even went so far as to suspect Haydn of wilfully trying to keep him back in his studies. It was only in his later years that this animosity gave way to the more general appreciation of his great predecessor, an expression of which is quoted at the beginning of this notice.

Haydn's visit to London was a succession of triumphs. Dr. Burney welcomed him with a laudatory poem, the various musical societies of the metropolis vied for his presence, and on July 8, 1791, he was created doctor of music by the university of Oxford. At court also he was received with every distinction, and the autonomy followed the royal example. Neither were more substantial rewards wanting. Haydn's engagement with Salomon was to write and conduct at the concerts in the Hanover Square Rooms six symphonies, and the success of these may be judged from the fact that at Haydn's benefit concert, for which £200 had been guaranteed to him, the receipts rose to £350. He also appeared at other concerts (one given by himself at Hanover Square Rooms, where amongst other works the *Suona Fonda* already referred to was performed), always with equal success. The same events were repeated in the following year, when the Salomon concerts began in February, and concluded with an extra concert in June. The symphonies known as the "Salomon Set," comprising some of Haydn's finest instrumental works, are the permanent record of the connexion of the two artists. In 1792 Haydn also went to hear the charity children at St. Paul's, whose singing produced on him as deep an impression as it did on Beethoven many years later. "I was more touched by this innocent and reverent music," he wrote in his diary, "than by any I ever heard in my life." Haydn left London in June 1792, but only to return in January 1794. In addition to his earlier works six new symphonies were played at the concerts of Salomon, which in the following year were given at the King's Concert-room and terminated on June 1, 1795, when Haydn appeared for the last time in England. In addition to valuable presents from royalty and other persons, he received £1200 by his second English visit, from which he returned to Vienna in the autumn of 1795, to resume once more his functions in the newly organized chapel of Prince Esterházy. He was now well stricken in years, and might have rested on his laurels. But so far from this being the case, the two works on

which—apart from his symphonies and sonatas—his immortality must mainly rest, belong to this last epoch of his life. These were the oratorio *The Creation*, and the cantata *The Seasons*. They were both written to German translations of English libretti, the former being compiled from *Paradise Lost*, the latter from Thomson's *Seasons*. *The Creation* was first performed in public on March 19, 1799, when its success was as immediate as it has since proved permanent. *The Seasons* was begun soon after the completion of *The Creation*, and finished in very little time. No one, delighted by the charm and spontaneity of its melodies, would suspect it to be the work of a feeble old man. Such, however, Haydn had now become. He wrote little after *The Seasons*, and his public appearances were few and far between. His old age was surrounded by the love of his friends and the esteem of the musical world, but his failing health did not admit of much active enjoyment. He was seen in public for the last time at a performance of *The Creation* in 1808. But his own music made so overpowering an impression on him that he had to be carried out of the hall. He died on May 31, 1809, during the occupation of Vienna by Napoleon's army, and many French officers followed his body to the grave.

Haydn's compositions comprise almost every form of vocal and instrumental music. Of his dramatic works, the operas are of infinitely less importance than *The Creation* and *The Seasons*. In the former there are points of grand and truly epical conception, surpassed by few masters except Handel, and the idyllic charm of the latter is as fresh to-day as it was eighty years ago. At the same time the great importance of Haydn in the history of music lies elsewhere. It was as an instrumental composer that he opened a new epoch of musical development. That amongst his 126 orchestral symphonies there are many extremely slight efforts is a matter of course. Even his finest symphonies, such as the celebrated *Suona Fonda*, or the one in E flat surmised in Germany "mit dem Paukenwirbel," on account of the characteristic drum-roll occurring in it, are pignions if compared with Beethoven's colossal efforts. At the same time it is true that without Haydn's modest subtraction Beethoven's mighty edifice would have been impossible. It was Haydn who first fixed the form of the symphony and gave it consistency of development. The lucid and harmonious treatment of his themes and the symmetrical structure of his symphonic movements remain still unsurpassed. And the same may be said in almost the same words of his string quartets, of which he wrote no less than eighty-three. It is by such works as these that Haydn has earned the name of father of instrumental music, generally and justly applied to him. At the same time it cannot be denied that there is in his works a certain want of intensity and depth. He avoids the high places of thought and passion, his path lies mostly in the smiling plains of humour and agreeable sentiment. In the former especially he excels, and it ought to be noted that his humour is of that peculiarly Viennese type which is as harmless as it is charming, and to the general influence of which even such serious composers as Beethoven and Brahms have had to submit. Some of Haydn's minuets especially seem to spring immediately from the consciousness of the people. How much he was at one with his nation is further proved by such a song as his "Gott erhalte Franz den Kaiser," which has become the Austrian national hymn, and is one of the rare instances in which a genuine Volkstied can be traced to a celebrated composer,—for generally the songs of the people as produced by the people. To sum up, Haydn's place in the history of his art will remain unassailed by all the changes musical taste has undergone since his time, or may still undergo. His melodies, though simple, are genuinely inspired, and will never lose their

charm, and his workmanship will remain an invaluable model of cleanness and symmetry. Haydn's life has been written by many pens and in many languages, Stendhal, the celebrated novelist, being amongst his French biographers. But all these earlier attempts have been thrown into the shade by the excellent works of HENRI C. F. POHL (*Mozart and Haydn in London*, 1867, *Joseph Haydn*, vol. 1, 1875, and the article "Haydn" in Grove's *Dictionary of Music and Musicians*), which are full of accurate and comprehensive research. To HENRI POHL all students of Haydn's life must confess themselves deeply indebted.

Two of Haydn's brothers acquired a certain amount of celebrity. JOHN MICHAEL HAYDN, born at Rohrau, September 14, 1737, and like his brother a chour-boy at St. Stephen's cathedral, became a prolific and able composer of masses and all kinds of church music. He lived during the greater part of his life at Salzburg, and his name is frequently mentioned in the biography of Mozart. Of his numerous compositions few have been printed. A mass in D is perhaps his masterpiece. He died August 10, 1806. The youngest brother, JOHANN HAYDN (born December 23, 1713, died May 20, 1805), had some reputation as a vocalist, and became, most probably by his brother's introduction, a singer in Prince Esterházy's chapel. (P. II.)

HAYDON, BENJAMIN ROBERT (1786-1846), historical painter and writer, was born at Plymouth, January 26, 1786. His mother was the daughter of the Rev. Benjamin Cobley, rector of Dordbrook, Devon, whose son, General Sir Thomas Cobley, signalized himself in the Russian service at the siege of Ismail. His father, a prosperous painter, stationer, and publisher, was a man of literary taste, and was well known and esteemed amongst all classes in Plymouth. Haydon, an only son, at an early date gave evidence of his taste for study, which was carefully fostered and promoted by his mother. At the age of six he was placed in Plymouth grammar school, and at twelve in Plympton St. Mary school. He completed his education in this institution, where Sir Joshua Reynolds also had acquired all the scholastic training he ever received. On the ceiling of the school room was a sketch by Reynolds in burnt cork, which it used to be Haydon's delight to sit and contemplate. Whilst at school he had some thought of adopting the medical profession, but he was so shocked at the sight of an operation that he gave up the idea. A perusal of Albinus, however, inspired him with a love for anatomy, and Reynolds's discourses aroused within him a smouldering taste for painting, which from childhood had been the absorbing idea of his mind. sanguine of success, full of energy and vigour, he started from the parental roof, May 14, 1801, for London, and entered his name as a student at the Royal Academy. He began and prosecuted his studies with such unwearied ardour that Fuseli, when asked when he ever found time to eat. At the age of twenty-one (1807) Haydon exhibited, for the first time, at the Royal Academy, *The Repose in Egypt*, which was bought by Mr. Thomas Hope the year after. This was a good start for the young artist, who shortly received a commission from Lord Mulgrave and an introduction to Sir George Beaumont. In 1809 he finished his well-known picture of *Dentatus*, which, though it brought him a great increase of fame, involved him in a life-long quarrel with the Royal Academy, whose committee had hung the picture in a small side room instead of the great hall. In 1810 his difficulties began through the stoppage of an allowance of £200 a year he had received from his father. His disappointment was embittered by the controversy in which he now became involved with Sir George Beaumont, for whom he had painted his famous picture of *Macbeth*, and Mr. Payne Knight, who had denied the beauties as well as the value of the *Elgin Marbles*. *The Judgment of Solomon*, his next

production, gained him £700, besides, £100 voted to him by the directors of the British Institution, and the freedom of the borough of Plymouth. To recruit his health and escape for a time from the cares of London life, Haydon joined his intimate friend Wilkie in a trip to Paris, he studied at the Louvre, and on his return to England produced his *Christ's Entry into Jerusalem*, which afterwards formed the nucleus for the American Gallery of Painting, which was erected by his cousin John Haviland of Philadelphia. Whilst painting *Lazarus* his pecuniary difficulties increased, and for the first time he was arrested but not imprisoned, the sheriff officer taking his word for his appearance. Amidst all these harassing cares he married in October 1821 a beautiful young widow, Miss Fyman, to whom he was devotedly attached. In 1822 Haydon was lodged in the King's Bench, where he received comforting letters from the first men of the day. Whilst a prisoner he drew up a petition to parliament in favour of the appointment of "a committee to inquire into the state of encouragement of historical painting," which was presented by Mr. Dighton. He also, during a second imprisonment in 1827, produced the picture of *The Mock Election*, the idea of which had been suggested by an incident that happened in the prison. The king (George IV) gave him £800 for this work. Among Haydon's other pictures were—1823, *Eacles*, and *Punch*, 1831, *Napoleon at St. Helena*, for Sir Robert Peel, *Xenophon*, on his Retreat with the "Ten Thousand," first seen at the Sea, and *Waiting for the Times*, purchased by the marquis of Stafford, 1832, *Falstaff*, and *Achilles playing the Lyre*. In 1834 he completed the *Reform Banquet*, for Lord Grey—this painting contained 197 portraits, in 1843, *Cutius Leaping into the Gulf*, and *Uziel and Satan*. When the competition took place at Westminster Hall, Haydon sent two cartoons, *The Curse of Adam*, and *Edward the Black Prince*, but had not the good fortune to gain a prize for either. He then painted *The Banishment of Aristides*, which was exhibited with other productions under the same roof where Tom Thumbe was then making his debut in London. The exhibition was unsuccessful, and the artist's difficulties increased to such an extent that, whilst employed on his last grand effort, *Alfred and the Trial by Jury*, overcome by debt, disappointment, and ingratitude, he wrote "Sketch me no longer on this rough world," and put an end to his existence with a pistol-shot, June 22, 1846, in the sixty-first year of his age. He left a widow and three children (various others had died), who, by the generosity of their father's friends, were rescued from their pecuniary difficulties and comfortably provided for, amongst the foremost of these friends were Sir Robert Peel, Count D'Orsay, Mr. Justice Talford, and Lord Campbell. Haydon began his first lecture on painting and design in 1835, and afterwards visited all the principal towns in England and Scotland. His delivery was energetic and imposing, his language powerful, flowing, and apt, and replete with wit and humour, and to look at the lecturer, excited by his subject, one could scarcely fancy him a man overwhelmed with difficulties and anxieties. The height of Haydon's ambition was to behold the first buildings of his country adorned with historical representations of her glory. He lived to see the acknowledgment of his principles by Government in the establishment of schools of design, and the embellishment of the new houses of parliament, but in the competition of artists for the carrying out of this object, the commissioners (amongst whom was one of his former pupils) considered, or affected to consider, that he had failed. Haydon was well versed in all points of his profession, and his *Lectures*, which were published shortly after their delivery, showed that he was as bold a writer as painter. It may be mentioned in this

connection that he was the author of the long and elaborate article, "Painting," in the 7th edition of the *Encyclopædia Britannica*.

To form a correct estimate of Haydon it is necessary to read his autobiography. This is one of the most natural books ever written, full of various and abundant power, and fascinating to the reader. The author seems to have dictated his feelings and sentiments without restraint as they rose in his mind, and his portrait stands in these volumes hunched to the life by his own hand. His love for his art was both a passion and a principle. He found patrons difficult to manage, and not having the tact to lead them gently, he tried to drive them fiercely. He failed, abused patrons and patronage, and intermingled talk of the noblest independence with acts not always dignified. His was self-willed to perversity, but his perseverance was such as to seldom associated with so much violence and passion. With a large fund of genuine self-reliance he combined a considerable measure of vanity. To the last he believed in his own powers and in the ultimate triumph of art. In taste he was deficient, at least as concerned himself. Hence the tone of self-assertion which he assumed in his advertisements, catalogues, and other appeals to the public. He proclaimed himself the apostle and martyr of high art, and believed himself to have on that account a claim on the sympathy and support of the nation. It must be confessed that he often tested severely those whom he called his friends. Every reader of his autobiography will be struck at the frequency and fervor of the short prayers interspersed throughout the work. Haydon had an overwhelming sense of a personal, overruling, and merciful providence which influenced his relations with his family, and to some extent with the world. His conduct as a husband and father entitles him to the utmost sympathy. In art his powers and attainments were undoubtedly very great, although his actual performances mostly fall short of the faculty which was manifestly within him; his general range and force of mind were also most remarkable, and would have qualified him to pursue in almost any path of intellectual exertion or of practical work. His eager and combative character was partly his enemy, but he had other enemies actuated by motives as unworthy as his own were always high pitched and on sublimated grounds laudable. Of his three great works—the Solomon, the Entry into Jerusalem, and the Lazarus—the second has generally been regarded as the finest. The Solomon is also a very admirable production, showing his executive power at its loftiest, and of itself enough to place Haydon at the head of British historical painting in his own time. The Lazarus, now in the National Gallery, is a more unequal performance, and in various respects open to criticism and censure, yet the head of Lazarus is so majestic and impressive that, if its author had done nothing else, we must still pronounce him a potent pictorial genius.

The chief authorities for the life of Haydon are *Life of B. R. Haydon, from his Autobiography and Journals*, edited and compiled by Tom Teylor, 8 vols., 1858, and *B. R. Haydon's Character, opinions, and Public Works*, with a memoir by his son, F. W. Haydon, 2 vols., 1870.

HAY FEVER, or **HYPERASTHMA**, or **SUMMER CATARRH**, a term applied to a catarrhal affection of the respiratory mucous membrane occurring in some individuals during the hay season, and generally believed to be due to the inhalation of the emanations from the spring grass (*Anthoxanthum odoratum*). It is an ailment of comparatively rare occurrence. The symptoms are those commonly presented in the case of a severe cold or influenza, consisting of headache, violent sneezing, and watery discharge from the nostrils and eyes, together with dry hard cough, and occasionally severe asthmatic paroxysms. The attack usually runs a course of from two to six weeks, unless cut

short by appropriate treatment, to which the complaint is in a considerable measure amenable. There is generally an annual recurrence of the disorder in those liable to it if they are exposed to its exciting cause, namely, the presence of hay. Symptoms of a similar character are produced in certain persons by the aroma of various flowers, by peacocks, and by the odour from cats, dogs, and rabbits. All such cases are examples of idiosyncrasy, and the individual is in general permanently susceptible to the influence of the excitant. In not a few instances an hereditary liability is traceable. The most efficient method of treatment in hay fever is to avoid the exciting cause, namely, the neighbourhood of grass fields, during the particular season. Removal to the seaside often succeeds in putting an end to an attack, and many persons who are liable to the complaint make such a change annually before its expected onset, and thus escape. For those who are unable to accomplish this, and must remain exposed to the noxious emanation, the use of a respirator is recommended. Of medicinal agents for affording relief during an attack, the usual remedies for asthma may be advantageously resorted to (see **ASTHMA**), while the use of the nasal douche with a weak solution of quinine and the employment of creosote or carbolic acid inhalations have been suggested.

HAYLEY, WILLIAM (1748–1820), the friend and biographer of Cowper, and grandson of William Hayley, dean of Chichester, was born in that city on the 9th November 1748. On account of mismanagement during a fever which he had while in a boarding school at Kingston, he was reduced to such prostration that the preservation of his life appeared to present only the promise of hopeless lameness and idiocy, but by careful nursing his health was gradually completely restored, and after some years' private tuition he pursued his studies at Eton and at Trinity College, Cambridge. In 1768 he procured a certificate of admission to the Middle Temple, London, but a short trial of legal studies was sufficient to dissipate the unexperienced preference which he had cherished for the profession of law. After his marriage in 1769 he stayed for some years chiefly in London, but in 1774 he retired to his paternal estate of Embsay in Sussex, resolved to spend the remainder of his days in rural quiet, with only such an amount of literary activity as might defray annuities and give a zest to life. Hayley made more than one attempt to succeed as a dramatic author, but first won fame by his poetical *Essays on Painting, History, and Epic Poetry*, and by his poem the *Triumph of Temper*. The success of these poems was partly attributable to the general dearth of poetic talent at the time, but they had also certain external qualities fitted to secure for them at least a temporary popularity, and his notes to his poetical essays also displayed very extensive reading, and exerted considerable influence in directing attention in England to the literature of Italy and Spain. On the death of Warton, Hayley was offered the laureateship, but declined it. In 1792 he made the acquaintance of the poet Cowper, and this acquaintance opened into a friendship which remained unbroken until Cowper's death in 1800. This beavement was separated by only a week from that caused by the death of Hayley's natural son Thomas Alphonso, who had given great promise of excellence as a sculptor, and, shunning from the associations now connected with Earsham, Hayley retired to what he called a "maime hermitage," which he had built at Felsham, and there resided till his death, November 20, 1820. Besides the *Life of Cowper*, published in 1803, Hayley was the author of a number of works in prose, which were not, however, so successful as his early poetical productions. Indeed the estimation in which he was held even during his lifetime depended perhaps more on his acquisitions and widely-cultivated tastes and his position

in society than on his achievements in literature. *The Memoirs of Hayley*, 2 vols. for writing which, to be published posthumously, he received a considerable allowance during the last twelve years of his life, appeared in 1833.

HAYNE, ROBERT YOUNG (1789-1810), American statesman, was born in St Paul's parish, Colleton district, South Carolina, on November 10, 1791. He studied law at Charleston, S C., and in his twenty-first year was admitted to the bar there, but in the same year (1812) served for a short time as a soldier in the war with Great Britain. Returning to practise in Charleston, Hayne was elected a member of the State legislature in 1814, and four years later became speaker. Shortly afterwards he accepted the post of attorney-general for his native State, though he declined the same office for the United States. On being elected a senator of the United States, Hayne at once showed himself an active foe to protective legislation, and vigorously combated the tariff of 1821 and 1828. A bill having been passed in 1832 removing the duty from those imports only which were not in competition with home manufactures, the state of South Carolina passed an ordinance nullifying the bill, on the ground that it was unconstitutional. President Jackson denounced this proceeding, and South Carolina, appointing Hayne governor, was preparing to defend its position by arms, when Congress made the desired change in the tariff, and South Carolina repealed its act. Hayne, on retiring from the governorship in 1834, was elected mayor of Charleston, and continued to take an active interest in public affairs till his death at Ashville, North Carolina, September 24, 1840. See *Life and Speeches of R. Y. Hayne*, 1845.

HAYTER, SIR GEORGE (1789-1871), principal painter in ordinary to the queen, was the son of a popular drawing-master and teacher of perspective who published a well-known introduction to perspective and other works. The son was born in London, and in his early youth went to sea. He afterwards studied in the Royal Academy, became a miniature painter, and was appointed in 1815 miniature-painter to the Princess Charlotte. He passed some years in Italy, more especially in Rome, returned to London towards 1826, resumed portrait painting, went chiefly in oil colour, executed many likenesses of the royal family, and attained such a reputation for finish and refinement in his work that he received the appointment of principal painter, and teacher of drawing to the princesses. In 1842 he was knighted. He painted various works on a large scale of a public and semi-historical character, but essentially works of portraiture, such as *The Trial of Queen Caroline* (189 likenesses), *The Meeting of the First Reformed Parliament*, now in the National Portrait Gallery, Queen Victoria taking the Oath of Abjuration (accounted his finest production), *The Marriage of the Queen*, and *The Trial of Lord William Russell*. The artistic merits of Hayter's works are not, however, such as to preserve to him with posterity an amount of *prestige* corresponding to that which court patronage procured him. He is not to be confounded with a contemporary artist, John Hayter, who produced illustrations for *The Book of Beauty*, &c.

HAYTI

Copyright, 1880, by John D. Chapman, jun.

PLATE
XIII HAYTI, HAITI, SANTO DOMINGO, or HISPAÑOLA, the largest, excepting Cuba, of the West India Islands, is situated between 17° 37' and 20° 0' N lat and 68° 20' and 74° 28' W long. Its greatest length, from Cape Engaño on the east to Cape Tiburon on the west, is 407 miles, its greatest breadth, from Cape Beate on the south to the farthest point on the north coast, is 160 miles, and its area is 28,000 square miles, or about the same as that of Ireland. From Cuba on the W.N.W. and from Jamaica

on the W.S.W. it is separated by the Windward Passage,—being distant from the former about 70 miles and from the latter about 130 miles,—and from Puerto Rico, which lies about 60 miles to the east, by the Mona Passage. In general form Hayti somewhat resembles a turtle, its eastern projection forming the head and the two western peninsulas the hinder limbs of the animal. The coast-line, which is estimated at about 1250 miles in length, has numerous projections and indentations. Of the peninsulas, the largest, on the south-west, of which Cape Tiburon forms the extremity, is 150 miles long by 20 to 40 wide, and the next largest, on the north-west, is 50 miles long with an average breadth of about 40 miles. Between these lies the Gulf of Gonave, a triangular bay, at the apex of which is the city of Port au Prince. The island of Gonave, about 27 miles from the city, is 36 miles long by 8½ miles broad. It divides the entrance to Port au Prince into two channels, both good, and forms within a safe anchorage of about 200 square miles in extent, but coral reefs near the coast oblige vessels of large draught to lie out about 1½ miles. Other ports in the Gulf of Gonave, north of Port au Prince, are St Marks, frequented for trade in coffee, and Gonaves, a large bay 4 miles deep, divided by a small island. At the extremity of the north-west peninsula is St Nicolas Mole, with an outer and an inner harbour, the latter landlocked and with good anchorage. Beyond, on the north coast, are Port de Paix, Anse Bay, Cape Haiti or Gnanaco, the Bay of Capaco (or Port Royal), and Port Liberté or Port Dauphin. From Port Liberté to Samana there is no good harbour on the north coast, Port Isabella being little more than an indentation in the coast, and the harbour of Puerto Plata being very shallow and beset with coral reefs. The Bay of Samana is formed by the peninsula of Samana, a mountain ridge projecting into the sea at the north-east extremity of the island. It is about 35 miles in length and from 6 to 10 miles in breadth. The bay is 30 miles long east and west, 10 miles broad north and south, and has an area of about 300 square miles. From the south coast a chain of coral reefs stretches across its mouth to within 1½ miles of the north shore, and the entrance is still further narrowed to about ⅓ of a mile by islets at the north extremity of the reef. There is, however, a good passage for ships of the deepest draught, and the bay inside is safe in all weathers. Beyond Samana, on the east and south coast, there is no port until Santo Domingo is reached, which has about 12 feet of water. West of Santo Domingo are the adjoining bays of Ocoa and Neiba, the former with an inlet called Caldesa Bay, which would be a good harbour if the coral reefs were removed. Jacmel, a nearly landlocked bay, open to the south-east, the Bay of Bassett, the ports of Aquin and St Louis, and the landlocked Anx Cayes. Between Anx Cayes and Port au Prince are Jérémie and the Bay of Baradères, the latter a good harbour. Besides Gonave, the principal islands are La Tortue or Tortuga, to the north, 23 miles long and 5 broad, once the stronghold of the buccanniers, La Saône or Adamant, off the south-east end of the island, 15 miles long by 3½ broad, Île de Vache, off Anx Cayes, 9 miles long by 2 broad, Great Cayemite, in the Bay of Baradères, 5 miles long by 3 broad, and La Beate, off the cape of the same name, 5 miles long by 2 broad. There are also many islets. Navassa, in the Windward Passage, is claimed by Hayti, but the title to it is not settled. It has been occupied since 1855 by a guano company from the United States.

Hayti is essentially a mountainous country, but there are many large and fertile plains between the several ranges. There are three distinct mountain formations,—the north range, the central, and the southern,—all of which have a general east and west direction. The northern chain, commonly called the Sierra de Monte Crista, extends from Cape

Samana on the east to the Sella de Caballo (3900 feet high) on the west, near Point Angata. The highest peak in this chain is Mount Diego Campo, near the middle part, which has an elevation of about 4000 feet. The central range begins near Point Macao on the east, extends west to about 70° 20' long, with an average height of about 1000 feet, and then divides into two distinct chains, the northernmost of which pursues a north-westerly course to Cape St Nicolas, while the other turns south west to Mount Ocoa, and then curves westward to the sea, which it reaches near St Marc. Near the west end of the island these two chains are connected by a secondary S shaped ridge. The northern limb of this central chain is called the Sierra del Cibao, and is the backbone of the island. The name Cibao is properly limited to the middle part, where, though there are occasional peaks more than 1000 feet higher, the average height is 7000 feet. At the east and are still higher elevations, Loma Tina and Pico del Yagui being each more than 9000 feet high. These are the two highest points on the island. The third or southernmost range of mountains begins near the Bay of Neiba, and runs due west to Cape Tiburon, forming the backbone of the south west peninsula. This range has no general name, but is called Babuaco at the east end, La Sella in the middle, from the peak of that name (nearly 9000 feet high), and La Motte towards the west end. The largest and finest of the great plains is La Vega Real (Doy le Plain), as it was named by Columbus, which lies between the middle part of the Cibao and the Monte Cristi ranges. It stretches from Samana Bay to Manzaniello Bay, and is about 140 miles long, with an average breadth of 14 miles. This valley is now commonly called the valley of Cibao, the name La Vega being confined to the eastern half, while the western is distinguished as the valley of Santiago. It is watered by the North or Gran Yagui river and the Yuna river and their affluents. The plain of Soybo stretches eastward from the river Ozama about 95 miles, with an average breadth of 16 miles, and is abundantly watered by the Ozama, Socu, Micoiri, Quabon, and Yuna rivers. Most of the large valleys and plains are in a state of nature, part savanna and part wooded, and well adapted for cattle raising. Of the rivers, the Gran Yagui rises in the Pico del Yagui, and after a tortuous course in a generally north-westerly direction falls into the Bay of Manzaniello. Its mouth is obstructed by shallows, and it is navigated only by canoes. The South Yagui, called also the Neiba or Nevra, rises in the Pico del Yagui and the Embre del Rio, and flows south into the bay of Neiba. The Yuna rises on Loma Tina, and flows east into Samana bay, it is navigable by vessels of light draft as far as its junction with the Ozama, and above that as far as Concepcion de la Vega by loaded canoes. The Ozama also is navigable for small vessels for 3 or 4 miles above its mouth. The largest lake is that of Enriquillo or Xaragua, which is 37 miles long by 8 broad. Though about 25 miles from the sea, its water is salt, as indicated in its French name Etang Sale, and has the same specific gravity as the ocean. It swarms with fish and with caymans. Other lakes are Lago de Fondo or Etang Samuñe, 16 miles long by 4 broad, which has brackish water, Ictea de Limon, 5 miles long by 2 broad, which has fresh water and no visible outlet, and the smaller Rincon and Miragoane.

The coast line of Hayti forms a portion of a considerable area of elevation. There are no active volcanoes in the island, but earthquakes are not infrequent. Rocks of various kind Secondary data have not yet been discovered, the most ancient, consisting of slates, conglomerates, and limestones, and forming as it were the core of the island, have been disturbed and intersected by intrusive masses of a syenitic character. Flanking the slates and other rocks of

the Sierra there is in the northern and in part of the southern side of Hayti a broad development of Tertiary deposits, which are skated by more recent limestones and gravels. The Sierra, forming the central mountain mass that runs the length of the eastern republic, and constituting in the main the peninsula of Samana, and also a small outlier near Porto Plata, is throughout composed of much-uplifted and usually strongly folded metamorphic rocks, which appear to have originally been clay shales, sandstones, sandstone conglomerates, and limestones. These are most disturbed in the western two thirds of the island, where they are broken in places by dykes. The quartz veins occurring in the slates near eruptive masses are auriferous, occurring in the sands of streams running through the metamorphic rocks, if in the neighbourhood of syenite. Thus the waters of the Nigua, Jaina, Nivao, Ocoa, and most of the tributaries of the Yagui that descend from the northern flank of Cibao carry gold, though rarely in any notable quantity. The lignite found in the Upper Miocene beds is exceedingly impure, and nowhere more than 3 or 4 inches in thickness. The mineral products include gold, platinum, silver, mercury, copper, iron, tin, manganese, antimony, sulphur, marble, opal, calcined lime, rock-salt, and bitumen, and mineral springs—ferrous, sulphurous, and of other kinds—abound. The fossil forms of the Miocene strata are allied to those of the west coast of South America, and forcibly suggest the conclusion that during some portion of the Miocene period the Pacific and Atlantic freely intercommunicated. For details concerning the geology of Hayti see Professor Gebb, *Trans Amer Phil Soc*, xv 49, and, on the Miocene fossils, Cuppy, *Quart Jour Geol Soc Lond*, xxxii, 1876, p 516.

The fauna of Hayti is not extensive. The agents is the largest wild mammal. Birds are few, excepting water fowl and pigeons. Snakes abound, though few are venomous. Lizards are numerous, and insects swarm in the low parts, with tananulas, scorpions, and centipedes. Lizards are found in the lakes and rivers, and the waters teem with fish and other sea food. Wild cattle, hogs, and dogs, descendants of those brought from Europe, roam at large on the plains and in the forests. The wild hogs furnish much sport to the natives, who hunt them with dogs trained for the purpose.

In richness and variety of vegetable products Hayti is not excelled by any other country in the world. All tropical plants and trees grow there in perfection, and nearly all the vegetables and fruits of temperate climates may be successfully cultivated in its highlands. Among its indigenous productions are cotton, rice, maize, tobacco, cocon, ginger, native indigo (*indigo maron* or *saurange*), arrowroot, manioc or cassava, pine-apple, banana, plantain, pine-apple, artichoke, yam, and sweet potato. Among its important plants and fruits are sugar cane, coffee, indigo (called *indigo franc*, to distinguish it from the native), melons, the legumes, cabbage, lucerne, guinea grass, bamboo, and the breadfruit, mango, casimite, orange, almond, apple, guape, mulberry, and fig. Most of the imported fruits have degenerated from want of care, and the bamboo has been attacked by an insect which prevents its wide diffusion, but the mango, now spread over nearly the whole island, has become almost a necessary article of food, the breadfruit has likewise become common, but is not so much esteemed. Hayti is also rich in woods, especially in cabinet and dye woods, among the former are mahogany, mimbrineal, satinwood, rosewood, cinnamon wood, yellow corno, and gr-gr, and among the latter are Brazil wood, logwood, fustic, and safflower. On the mountains are extensive forests of pine and a species of oak, and in various parts occur the locust, ironwood, cypress or Bermuda cedar, palmetto, and many kinds of palms.

Hayti possesses a great diversity of climate. In the plains, where it is generally hot and moist, the thermometer often rises to 96° and sometimes to 100°, but in the high lands the readings are seldom above 76° or below 60°. In the most elevated parts a fire is sometimes agreeable. The seasons are divided into the wet and dry. Rains are heaviest and most frequent in May and June, when the rivers, some of which have but a scanty supply of water in the dry season, flood portions of the plains. Hurricanes are not so frequent as in the Windward Islands, but violent gales often occur. The prevailing winds are from the east.

Agriculture is very backward, and the implements used are rude. The staple productions for which the island was once famous are now imperfectly cultivated or neglected altogether. Mining, once profitably carried on, is generally abandoned from lack of capital, though some gold washing still continues in the northern streams. Some mahogany and dyewoods are cut in the interior, and hides, wax, and honey are collected for export, but on a comparatively small scale. The business of the country is chiefly in the hands of foreigners, settled in the cities and larger towns.

The population of the island is about 700,000, of which 550,000 are subjects of the Haytian republic in the west, and 150,000 of the Dominican republic in the east. Of the Haytian population nearly 500,000 are of African descent, of the Dominican about 26,000. Of the mixed race about 125,000 are of Spanish, and 50,000 of French descent. There are also a few Germans, Italians, and natives of the United States, settled chiefly in the coast towns. The language of the eastern end of the island is Spanish, that of the western an impure French patois.

The history of Hayti begins with its discovery by Columbus who landed at St. Nicolas Mole, Dec. 6, 1492, having left Cuba the day before. The island was then occupied by about 2,000,000 people of a low type of humanity, who are described by the Spanish historians as feeble in intellect, and morally and physically defective. The natives called the island Haiti (mountainous country) and Quisqueia (vast country). Columbus named it Española (Little Spain), which was Latinized into Hispaniola. Adventurers from Europe, attracted chiefly by the exaggerated stories of gold, flocked thither, and the natives were reduced to slavery, although many made a gallant resistance. After about 30 years of grinding servitude, nearly all the aborigines had disappeared. A few negroes were brought into the colony as early as 1500, and in 1517 a royal edict authorized the importation from Africa of 4000 negroes a year. The blacks, stronger and better able to bear the labour which had been death to their predecessors, multiplied to such a degree that the island has finally passed into the hands of their descendants. About 1630 a mixed colony of French and English, who had been driven out of St. Christopher by the Spaniards, established themselves in the island of Tortuga, where they soon grew formidable under the name of buccaniers. They at last obtained a footing on the mainland of Hayti, into which they had previously made only predatory excursions, and by the treaty of Ryewick (1697) the part of the island which they held was ceded to France. This colony, called Saint Domingue, languished for a while under the restrictions imposed on its trade by the mother country, but after 1722, when these were removed, it attained a high degree of prosperity, and it was in a flourishing state when the French Revolution broke out in 1789. The population was then composed of three classes,—whites, free people of colour (mostly mulattoes), and slaves. The free people of colour, some of whom were wealthy proprietors, demanded that the principles of the Revolution should be extended to them, this was opposed by the whites, who had previously engrossed all the public honours, and the two classes were

already violently inflamed against each other when the national convention (1791) passed a decree giving to the mulattoes all the rights of French citizens. The whites adopted at once the most violent measures, and appealed to the mother country for a reversal of the decree. But when the mulattoes took up arms for their defence at the time of the insurrection of the plantation slaves (August 23, 1791), the whites endeavoured to conciliate them. In the meantime the home Government reversed the decree granting them political rights. The mulattoes now took part with the blacks, and a most destructive war raged for several years, during which each party seemed to study to outdo the other in acts of cruelty. Commissioners were sent out from France, with full power to settle the quarrel, but could effect nothing. In 1793 the abolition of slavery in the colony was proclaimed. In September of the same year a British force invaded the island, but, though some partial advantages were gained, the climate made sad havoc among the troops, and prevented any solid success. Toussaint l'Ouverture, the leader of the blacks, came to the aid of the French, the home Government having in the meantime ratified the act of the commissioners in freeing the slaves. He was made commander-in-chief of the French army, and in 1798 forced the British to evacuate the island. By the treaty with Spain, made at Basel in 1795, France had acquired the title to the entire island, which now received the name of Saint Domingue.

In 1801 Toussaint, then master of the whole country, adopted a constitutional form of government, in which he was to be president for life. Bonaparte, then first consul of France, determined to reduce the colony and restore slavery, sent to Hayti 25,000 troops under General Leclerc. The blacks were compelled to retire to the mountains, but kept up a desultory war under Toussaint's able leadership. Leclerc, wearied of the war, enjoined the negro chiefs to a suspension of arms, and having invited Toussaint to an interview, seized him and sent him to France, where he died in prison in 1803. The blacks, infuriated by this act of treachery, renewed the struggle under Dessalines with a barbarity unequalled in the previous contests. The French, further embarrassed by the appearance of a British fleet off the coast, now gradually lost ground, and in 1803 agreed to evacuate the island. On the 30th of November of that year, 8000 French troops surrendered to the British squadron. In 1804 independence was declared, and the aboriginal name of Hayti was revived. Dessalines was made governor for life, but in October of the same year he proclaimed himself emperor, and was crowned with great pomp. He soon began to display the cruelty of a tyrant, and in 1806 he was assassinated. His position was now contended for by several chiefs, one of whom, Christophe, established himself in the north, while Pétion took possession of the southern part. The Spaniards re-established themselves in the eastern part of the island, retaining the French name, modified to Santo Domingo. Civil war now raged between the adherents of Christophe and Pétion, but in 1810 hostilities were suspended. Christophe declared himself king of Hayti under the title of Henry I., but his cruelty caused an insurrection, and in 1820 he committed suicide. Pétion had died in 1818, and was succeeded by Gen. Boyer, who, after Christophe's death, made himself master of all the French part of the island. In 1821 the eastern end of the island proclaimed its independence of Spain, and Boyer, taking advantage of dissensions there, invaded it, and in 1822 the dominion of the whole island fell into his hands. Boyer held the presidency of the new government, which was called the republic of Hayti, until 1843, when he was driven from the island by a revolution. In 1844 the people of the eastern end of the island again asserted their independence, and estab-

The enumeration of 1868, which extended over an area of 3000 square miles (including the feudist territory of Jambh, showed a population of 807,218 (in 1861, 1,012,422, females, 175,795). The Mohammedans numbered 816,112; Hindus, 18,668; Sikhs, 972; "others," 1370. The gross income, in 1875-76 was £26,392. In the same year the police force numbered 5100 men, besides 380 village watchmen, and there were 24 schools with 1042 pupils. The principal crops consist of wheat, barley, oil seeds, maize, rice, indigo, millets, and cotton. Out of a cultivated area of 893,018 acres, 56,380 were artificially irrigated by means of wells and embankments on the rivers and hill torrents. Hazara has not suffered from any calamity since the famine of 1783, which affected it as well as the rest of Upper India. The chief occupations are English cloth, salt, indigo, and the exports *ghee*, mustard oil, barley, wheat, rice, and live stock. In 1875-76 there were 878 miles of unenclosed roads within the district. The average rainfall for the eight years ending 1873-74 amounted to 47 inches. The station of Abbottabad is the headquarters of the Punjab frontier force. *History*—The name *Hazara* probably belonged originally to a Turki family which settled in India with Timur in the 13th century, and subsequently settled in the remote region. During the prosperous period of the Mughal dynasty, the population included a number of mixed tribes, which each began to assert its independence, so that the district gradually prevailed until the time when *Hazara* attracted the attention of the young Sikh monarchy. Ranjit Singh first obtained a footing in the district in 1818, and, after eight years of constant aggression, became master of the whole country. During the minority of the young Maharaja Durbh Singh, the Sikh capital fell into a state of complete anarchy, and the people seized the opportunity for asserting their independence, and rose in 1818 in rebellion. They stormed the Sikh forts, laid siege to Haunpur, and drove the governor across the border. In the following year a great part of the district was included in the territory ceded to *Ghalib Singh* by the British, at the conclusion of the first Sikh war. On the outbreak of the second Sikh war the troops in *Hazara* were ordered to the frontier. The British government, however, did not permit Abbottabad to be taken by the Sikhs, and the insurrection was soon quelled. Since then *Hazara* has passed under direct British rule, and has enjoyed for more than quarter of a century uninterrupted peace.

HAZARAS

See ARITHMETIC.

HAZARD, a game played with dice. The player or "caster" calls a "man" (that is, any number from five to nine inclusive). He then throws with two dice. If he "throws in," or "nicks," he wins the sum played for from the banker or "setter." Five is a nick to five, six and twelve are nicks to six, seven and eleven to seven, eight and twelve to eight, and nine to nine. If the caster "throws out" by throwing aces, or deuce, ace (called *clabs*), he loses. When the man is five or nine the caster throws out with eleven or twelve, when the man is six or eight he throws out with eleven, when the man is seven he throws out with nine, the caster neither nicks nor throws out, the number thrown is his "chance" and he keeps on throwing till either the chance comes up, when he wins, or till the man comes up, when he loses. When a chance is thrown, the "odds" for or against the chance are laid by the setter to the amount of the original stake.

Suppose, for example, 7 is the man. If the caster throws 7 or 11 he wins, if he throws ace, deuce, or 12 he loses. If he throws any other number, that is his chance. Say 7 is the man and 4 the chance, the odds against the caster are now 2 to 1 (it will appear from the table below). If the stake were £1, the setter would lay £2 to £1 in addition. The caster goes on throwing till either 7 or 4 appears, when he loses £2 or wins £3.

In trying the odds, the setter gains no advantage, as can easily be shown, examining the various ways in which two dice can be thrown.

	2 and 1,	3 and 2,	4 and 3,	5 and 4,	6 and 5,	7 and 6,	8 and 7,	9 and 8,	10 and 9,	11 and 10,	12 and 11,	12 and 12,
2	1											
3	2	1										
4	3	2	1									
5	4	3	2	1								
6	5	4	3	2	1							
7	6	5	4	3	2	1						
8	5	4	3	2	1							
9	4	3	2	1								
10	3	2	1									
11	2	1										
12	1											

in all 36 ways. The table shows that there are six ways in which 7 can be thrown, three ways in which 4 can be thrown. Hence the odds are 6 to 3, or 2 to 1.

That there is always an advantage in favour of the setter on the stake just played for. The least disadvantageous man for the caster to call is 7.

Take the case in which 7 is the man and £18 (to avoid fractions) the stake. The odds are 2 to 1 therefore the setter calls 7. Then he calls 7 or 11 is thrown the caster wins. There are eight ways out of 36 in his favour, therefore his expectation on making is $\frac{8}{36}$ of £18=£4. (2) If the chance is 6, in order to win he must throw 6 or 12 he gets the stake &c. There are five ways of throwing 6 and six ways of throwing 7. His expectation on 6 is therefore $\frac{11}{36}$ of £18=£4.5 5/6. (3) The expectation on a chance of 8 is the same as on 6, viz. £4.5 5/6. (4 and 5) If the chance is 9 or 3 the expectation is $\frac{4}{36}$ of £18=£2. (6 and 7) If the chance is 10 or 4 the expectation is $\frac{3}{36}$ of £18=£1. (8 and 9) The total expectation of the caster is all the separate expectations added together, viz. £17.14s. 11d. If his expectation is less equal to the stake &c, it should amount to £18. Therefore the caster's expectation is 6s. 10d. less than it would be if the probabilities of his winning or losing were equal. This makes his disadvantage, when 7 is the man equal to £1 and half a farthing in the pound.

The calculations applied to the man of 7 can easily be made use of for any other man, when it will be found that the caster's expectation of loss when 6 or 9 is the man is £1 and 1/2 in the pound, when 6 or 9 is the man, £1 and nearly half a farthing in the pound.

HAZARIBAGH, a British district in the lieutenant-governorship of Bengal, India, lying between 23° 25' and 24° 48' N lat. and between 84° 29' and 86° 38' E long. It is bounded on the N by the districts of Gaya and Monghyr, on the E by the Santal Parganas and Mamhatra divisions, on the S by Lohardaga, and on the W by Chota Nagpur division, and has an area of 7020 square miles.

The physical formation of Hazaribagh exhibits three distinct features—(1) a high central plateau occupying the western section, the surface of which is undulating and cultivated, (2) a lower and more extensive plateau stretching along the north and eastern portions, to the north, the land is well cultivated, while to the east the country is of a more varied character, the elevation is lower, and the character of a plateau is gradually lost, (3) the central valley of the Damodar river occupying the entire southern section. Indeed, although the characteristics of the district are rocky hill, and wide spreading jungle, fine patches of cultivation are met with in all parts, and the scenery is generally pleasing and often picturesque. The district forms a part of the chain of high land which extends across the continent of India, south of the Nerbudda on the west, and south of the Són river on the east. The most important river of Hazaribagh is the Damodar, with its many tributaries, which drains an area of 2450 square miles. The only other river of any importance is the Bakania. The jungle gives shelter to wild animals of all sorts. Game birds are plentiful.

The census of 1875 showed a population of 771,875 (males, 397,045; females, 374,830). Belonging to aboriginal tribes there are 87,120, semi-Hindustani aborigines, 210,712, Hindus, 421,032, persons of Hindu origin not recognizing caste, 2664, Mahomedans, 23,338, non-Aryans, 1862, and naturalised, 67. The principalities contained more than 6000 inhabitants—Hazaribagh, 11,060, Jhark, 3999, and Chatra, 8118. The only place of special interest is Purneah Hill, a celebrated place of pilgrimage, which is annually visited by large numbers of devotees who stampede there in 1870 amounted to £28,841, and the expenditure to £21,887. The regular police force (1873) numbered 867 men of all ranks, municipal force, 65, and local police, 3384 men, maintained at a total cost of £74,788. There were 1873, 868, 67. The principal crops are rice, wheat, and the staple crop, and the three principal kinds are grown. Amongst the other crops are wheat, barley, Indian corn, the usual pulses and green crops of Bengal, jute, &c., also, sugarcane, opium, cotton, &c. The trade is concentrated at Chatra, the great central market. The chief exports are jute, metal cooking utensils, *ghee*, iron, and cattle, and the imports, rice, salt, cattle, and tobacco. There are 400 miles of road, but coal has not been known to exist in the district, the most important being that of Karharbari, which is capable of supplying 260,000 tons a year for 800 years. In 1877 there were three tea plantations containing mature plants, and one on Purneah Hill which promises well. The average mean temperature for 1874 was 74° F., the average

only a small, 52 1/2 inches. The climate is very healthy, but the rainfall, 50, and country are not uncommon, choleric and.

The history of the district is involved in obscurity until 1766, about which time a certain Blackett Smith was chief of the country. In a few years he was succeeded by a Tyi Sank, who had gained the assistance of the British. In 1780 Hainburg, along with the surrounding territory, passed under direct British rule.

HAINBURG, the chief town and administrative head-quarters of the above district, is picturesquely situated on the high central plateau of the district, at an elevation of 2000 feet above sea level, and in the midst of a group of conical hills, 23° 59' 21" N lat and 85° 34' 32" E long. The town is little more than a cluster of villages, with intervening cultivation, which have sprung up round the military *ba* di. Hainburg has been the military head-quarters of the district since 1780, and the seat of civil administration since 1834. The continent lies south-east of the town. Population in 1872, 11,050 (6312 mil., 4738 females).—Hindus, 7210, Mahometans, 3381, Christians, 52, "others," 371.

HAZEBROUCK, a town of France, capital of an arrondissement of the same name in the department of Nord, is situated on the Douie, 32 miles W N W of Lille, in a district formerly covered with marshes. It stands on the Lille and Calais Railway, at the junction of the branch from Dunkirk. The town is governed by a sub-prefect, and has a court of primary instance with two judges de paix, besides various offices of justice and inland revenue. There are numerous religious and charitable societies, including the Frères des Ecoles Chrétiennes, Sociés de Chant, and Dames de la Sainte Union. The convent of Capuchins, built near the town in 1861, is now occupied by a school. Hazebroeck contains some handsome public buildings, as the church of St Nicolas, with a tower 200 feet high, of fine open work, built about 1520, the hôtel de ville (1807-1813), the prison for the department, two theatres, and the communal college. The Augustinian convent, built in the 16th century, with a façade of the 17th century, is now occupied in its several parts by the hospital, a tobacco warehouse, a market, and college lecture room. A chamber of agriculture meets in the town, where there are also a small public library and a secondary school. The principal manufactures are linen cloth, thread, soap, beer, oil, lime, and salt. There are also tanneries, salt refineries, corn-mills, and dye works. Trade in country produce, cattle, timber, and hops is also carried on. Population (1876) of the district 9857, of the town 6363.

HAZEL (Anglo-Saxon, *Hasel*;¹ German, *Hasel*, French, *Haselier*, *Coudier*), *Corylus*, Tournem., a genus of shrubs or low trees of the natural order *Umbelliferae* and sub order *Coryleae*. The common hazel, *Corylus Avellana*, L., is distributed throughout Europe, in North Africa, and in Central and Russian Asia, except the northernmost parts. It is commonly found in hedges and coppices, and as an undergrowth in woods, and reaches a height of some 12 feet, occasionally, as at Eastwell Park, Kent, it may attain to 30 feet. According to Evelyn (*Sylva*, p. 85, 1664), hazels "above all affect cold, barren, dry, and sandy soils, also mountains, and even rocky ground produce them, but most plentifully if somewhat moist, dankish, and mossy." In Kent they flourish best in a calcareous soil. The bark of the older stems is of a bright brown, mottled with grey, that of the young twigs is ash-coloured, and glandular and hairy. The leaves are alternate, from 2 to 4 inches in length, downy below, roundish-ovate, pointed, and shortly petiolate, occasionally they are found with the margins ciliate at the base, or with the disk so depressed as to

form a pitcher-like structure (Mastons). In the variety *C. purpurea*, the leaves, as also the peltide of the leaf and the husk of the nut, are purple, and in *C. heterophylla* they are thickly clothed with hairs. In autumn the rich yellow tint acquired by the leaves of the hazel adds greatly to the beauty of landscapes. The flowers are monoecious, and appear in Great Britain in February and March, before the leaves, and sometimes in October (London). The cylindrical, drooping, and yellow male catkins (see BOTANY, vol. iv p. 123, fig. 161) are 1 to 2 1/2 inches in length, and occur 2 to 4 in a raceme, when in unusual numbers they may be terminal in position. The female flowers are small, subglobose, and sessile, resembling leaf-buds, and have protruding crimson stigmas, the minute inner bracts, by their enlargement, form the palmately lobed and cut involucre or husk of the nut. The ovary is not visible till nearly midsummer, and is not fully developed before autumn. The nuts have a length of from 1/2 to 2 inch, and grow in clusters. Double or triple nuts are the result of the equal development of two or all the three carpels of the original flower, of which ordinarily two become abortive. Fusion of two or more nuts is not uncommon, and Mastens gives an instance of the union of as many as five. From the light brown or brown colour of the nuts the terms *hazel* and *hazelly*, i.e., "in hue as hazel nuts" (Stuckesbury, *Flora of the Silesia*, ii. 1), derive their significance.² The seed of the hazel is whitish red, close in texture, and plant, and has within it a weight of 40 lb per cub foot, it has been used in cabinet making, and for toys and turned articles. Curiously veined veneers are obtained from the roots, and the root shoots as a largely employed in the making of crates, coal coives or baskets, handles, with bands, whip-handles, and other objects. The rods are reputed to be most durable when from the driest ground, and to be especially good where the bottom is chalky. The light charcoal afforded by the hazel serves well for crayons, and is valued by gunpowder manufacturers. An objection to the construction of hedges of hazel is the injury not infrequently done to them by the nut-gatherers, who "with active vigour crushes down the tree" (Thomson's *Seasons*, "Autumn"), and otherwise damages it.

The filbert,³ among the numerous varieties of *Corylus Avellana*, is extensively cultivated, especially in Kent, for the sake of its nuts, which are readily distinguished from cob nuts by their ample involucre and greater length. It may be propagated by suckers and layers, by grafting, and (see ARBORICULTURE, ii. 322) by sowing. Suckers afford the strongest and earliest bearing plants. Grafted filberts are less liable than others to be encumbered by suckers at the root. By the Maidstone growers the best plants are considered to be obtained from layers. These become well rooted in about a twelvemonth, and then, after pruning, are bedded out in the nursery for two or three years. The filbert may be economically grown on the borders of plantations or orchards, or in open spots in woods. It thrives most in a light loam with a dry subsoil, rich and, in particular, wet soils are unsuitable, conducing to the formation of too much wood. Plantations of filberts are made in autumn, in well-drained ground, and a space of about 10 feet by 8 has to be allowed for each tree. Ground good for hops is good also for filberts, according to Williamson, who recommends old woollen rags as the best manure for the latter ("On the Cultivation of the Filbert," *Trans Hort Soc*, iv. 145). In the third year after planting the trees may require root pruning, in the fifth or sixth they should bear well. The nuts grow in greatest abundance on the extremities of second year's branches, where light and air have

¹ Derived, it has been supposed, from Ang. Sax. *Has*, a basket, connoted with *Hasen* = German, to give others the hazel-wood was the sceptre of authority of the Saxon chieftain (*trough* *Hasel*) of olden times. See Grimm, *Gesch. d. deutsch. Sprache*, p. 1016, 1848.

² On the expression "hazelly eyes," see *Notes and Queries*, 2d ser., xii. 337, and 3d ser., i. 18, 39.

³ For derivations of the word see Latham's *Johnson's Dictionary*.

whose temper was fitful and moody, and the intensity of whose passions rendered him for the time unsensible to the feelings and rightful claims of those who might stand in the way of their gratification. The dissolution of the ill-assorted union was nevertheless deferred for fourteen years, during which much of his best literary work had been produced. After three or four years, during which he almost disappeared from observation, he came forward prominently as a writer in the *Edinburgh* and as a lecturer at the Surrey Institution, bringing out in rapid succession his *Round Table*, a collection of essays on literature, men, and manners; his *View of the contemporary English stage*, and his lectures on the poets, the English comic writers, and the dramatic literature of his age of *Shakspeare's Plans* (1817), and his *Table Talk* (1821), his reputation as a critic and essayist was mainly be-sure. Next to Coleridge, Hazlitt was, perhaps the most powerful exponent of the dawning perception that Shakspeare's art was no less marvellous than his genius, and Hazlitt's criticism did not, like Coleridge's, remain in the condition of a series of brilliant but fitful glimpses of insight, but was elaborated with steady care. His lectures on the Elizabethan dramatists performed a similar service for the reader, sweeter, and simpler among them, such as Dekker, till then unduly eclipsed by later writers, better playwrights, but worse poets. The passing of the contemporary drama, he successfully vindicated for Edmund Kean (whom, however, he had at first disparaged) the high place which he has retained as an actor, while his criticisms on the English comic writers and men of letters in general are masterpieces of ingenious and felicitous exposition, though rarely, like Coleridge's, penetrating to the inmost core of the subject. As an essayist Hazlitt is even more effective than as a critic, for this style of composition allows more scope to the talking individuality of his character. Being enabled to select his own subjects, he escapes dependence upon others either for his matter or his illustrations, and presents himself by turns as a metaphysician, a moralist, a humanist, a painter of manners, and characteristics, but always, whatever his ostensible theme, darning the essence of his commentary from his own bosom. This combination of intense subjectivity with strict adherence to his subject is one of Hazlitt's most distinctive and creditable traits. Intellectual truthfulness is a passion with him. He stoops his topic in the hues of his own individuality, but never uses it as a means of self-display. The first reception of these admirable essays was by no means in accordance with their deserts. Hazlitt's political sympathies and antipathies were vehement, and he had taken the unfashionable side. The *Quarterly* attacked him with deliberate malignity, stopped the sale of his writings for a time, and blighted his credit with publishers. He had become estranged from his early friends, the Lake poets, by what he uncharitably but not unnaturally regarded as their political apostasy, as well as by an escape of his own, obscurely related, but apparently not creditable. His inequalities of temper separated him for a time even from Leigh Hunt and Charles Lamb, and on the whole the period of his most brilliant literary success was that when he was most soured and broken. Domestic troubles enveloped, his marriage, long little more than nominal, was dissolved in consequence of the infatuated person he had conceived for a servant girl, a most ordinary person in the eyes of every one else. It is impossible to regard Hazlitt as a responsible agent while he continued subject to this influence. His own record of the transaction, published by himself under the title of *Love Amour, or the New Pygmalion* (1823), is a most remarkable psychological curiosity, and one of the most signal examples extant of the power of

genuine passion, not merely to palliate what is wrong, but to dignify what is odious. "His idolatry," says Mrs. Jameson, "in its intense earnestness and reality assumes something of the sublimity of an act of faith." The business-like dissolution of his marriage under the law of Scotland is related with amazing naïveté by the family biographer. Rid of his wife and cured of his mistress, he shortly afterwards astonished his friends by marrying a widow. "All I know," says his grandson, "is that Mrs. Bridgewater became Mrs. Hazlitt." They travelled on the Continent for a year, and then parted never to meet again. Hazlitt's study of the Italian masters during this tour, described in a series of letters contributed to the *Morning Chronicle*, had a deep effect upon him, and perhaps conduced to that intimacy with the cynical old painter Northcote which, shortly after his return, engendered a curious but eminently readable volume of conversations with him. The respective shares of author and artist are not always easy to determine. During the recent agitations of his life he had been writing essays, collected in 1828 under the title of *The Plain Speaker*, others subsequently written were published after his death. They are in no respect inferior to his earlier performances. *The Spirit of the Age* (1825), a series of criticisms on the leading intellectual characters of the day, reveals that he was long qualified to assign their true place to contemporaries than to revise the verdicts of the past, but is in point of style perhaps the most splendid and copious of his compositions. It is eager and animated to impetuosity, with no trace of carelessness or disorder. He now undertook a work which was to have crowned his literary reputation, but which can hardly be said to have even enhanced it—*The Life of Napoleon* (1828–30). The undertaking was at best premature, and was inevitably disfigured by partiality to Napoleon as the representative of the popular cause, excusable and even becoming in a Liberal politician writing in the days of the Holy Alliance, but preposterous now that the true tendencies of French imperialism are recognised. Owing to the failure of his publishers Hazlitt received no recompense for this laborious work. Pecuniary anxieties and disappointments may have contributed to hasten his death, which took place on September 18, 1830. Charles Lamb was with him to the last.

With many serious defects both on the intellectual and the moral side, Hazlitt's character in both had at least the merit of sincerity and consistency. He was a compound of intellect and passion, and the refinement of his critical analysis is associated with vehement eloquence and glowing imagery. He was essentially a critic, a disector, and, as Bulwer justly remarks, a much better judge of men of thought than of men of action. But he also possessed many gifts in no way essential to the critical character, and transcending the critic's ordinary sphere. These, while giving him rank as an independent writer, frequently perturbed the natural clearness of his critical judgment, and seduced him into the paradoxes with which his works abound. These paradoxes, however, never spring from affectation, as they are in general the sallies of a mind so agile and ardent as to overrun its own goal. His style is perfectly natural, and yet admirably calculated for effect. His diction, always rich and masculine, seems to kindle as he proceeds, and when thoroughly animated by his subject, he advances with a succession of energetic, hard-hitting sentences, each carrying his argument a step further, like a champion dealing out blows as he presses upon his enemy. Although, however, his grasp upon his subject is strenuous, his insight into it is rarely profound. He can amply satisfy men of taste and culture, he cannot, like Coleridge or Burke, dissatisfy them with themselves by showing them how much they would have missed without him. He belongs to the

class of critics that exhibits the beauties of an author, rather than to the class that reveals them. He was somewhat backward in appreciating contemporary merit, he venerated Coleridge's intellect, but his estimate of his poetry is ridiculously low, his review of Shelley's posthumous poems, though rhetorically fine, is critically poor, and he did little to vindicate the fame of Keats. As a moralist and observer of manners his chief merit consists in the extreme felicity of his occasional observations. But all shortcomings are forgotten in the genuineness and fervour of the writer's self-portraiture, and the bold relief in which he stands out from the crowd of mankind. The intensity of his personal convictions causes all he wrote to appear in a manner autobiographic. Other men have been said to speak like books, Hazlitt's books speak like men. To read his works in connexion with Leigh Hunt's and Charles Lamb's is to be introduced into one of the most attractive of English literary circles, and this alone will long preserve them from oblivion.

The most copious source of information respecting H is his biography by his grandson (1867), a ready rather than a memoir, yet full of interest. A slight but appropriate sketch had previously been provided by his son to the posthumous essays published in 1886, accompanied by elegant but partial estimates of his intellectual character by Bulwer and Talfourd. Valuable biographical particulars have been preserved in Bray's Cornhill's notices of Lamb, and in the reminiscences of Mr P G Patmore, Hazlitt's most intimate associate in his latter years. A full bibliographical list of his writings, with a collection of the most remarkable critical judgments upon them from foreign quatuors, has been lastfully and industriously prepared by Mr Alexander Ireland (1888). (R G)

HEAD, SIR EDMUND WALKER, BART, (1805-1868), a popular writer on art, was born in 1805 at Watton Place, near Maidstone in Kent. He was educated at Winchester school and Otter College, Oxford, and taking his degree with first-class honours in classics, he became in 1827 fellow of Merton College, and in 1834 university examiner in classics. Two years later he married, and on his father's death in 1838, he succeeded to the baronetcy as eighth baronet. His services as poor-law commissioner, to which post he was appointed in 1841 after three years as assistant-commissioner, procured for him in 1847 the office of lieutenant-governor of New Brunswick, whence he passed in 1854 to the governor-generalship of Canada, which he retained till 1861. The following year, having returned to England, Head was nominated a civil-service commissioner. In 1857 he was sworn of the Privy Council, and in 1860 was decorated as K C B, while in the course of his career he received the degrees of D C L at Oxford and LL D at Cambridge. He died in London, January 28, 1868.

Sir Edmund Head wrote the title "Painting," in the *Penny Cyclopædia: A Handbook of the Spanish and French Schools of Painting*, 1845, *Shall and Will*, or two chapters on future *Availability*, 1856, and *Ballads and other Poems, original and trans late*, 1, 1868. He also edited *A Handbook of Painting of the German, Flemish, Dutch, Spanish, and French Schools*, 1864. His translation from the Icelandic of *Viga Glum's Saga* appeared in 1865.

HEAD, SIR FRANCIS BOND, BART (1793-1876), soldier, traveller, and author, son of James Roper Head of the Hermitage, Kent, was born there January 1, 1793. He served with the Royal Engineers at the battles of Waterloo and Fleurus, and when he returned from the army he had risen to the rank of major. In 1825 he accepted the charge of an association formed to work the gold and silver mines of Rio de la Platte. In connexion with this enterprise he made several rapid journeys across the Pampas and among the Andes, his *Rough Notes* of which, published in 1826, and written in a clear and spirited style, obtained for him the name of "Galloping Head." In 1835 he was appointed governor of Upper Canada, where he manifested similar energy in dealing with the discontents from which the colony was at that time suffering. He resigned his

office in 1837, and in recognition of his services he was in 1838 created a baronet. His narrative of his administration in Upper Canada was published by him in 1839. In 1867 he became a privy councillor. He died at his residence at Choydon, July 20, 1875. Some time previously a pension of £100 per annum was conferred upon him for his "services to literature."

Sir Francis Head was the author of a considerable number of works, chiefly of travel, written in a clever, amusing, and graphic fashion, and displaying both acuteness and a personal touch, which have all gone through more than one edition, are *Bubbles from the Bottom of Niagara*, 1838, *Life of Brierley*, 1844, *The Emigrant, May, Stokers and Poets*, 1850, *The Lays of the State of Great Britain*, 1850, *A Faggot of French Stick*, 1851, *A Fortnight in Ireland*, 1852, *Demerits of Demerit*, 1855, *The House and the India*, 1860, *The Royal Engineers*, 1870.

HEAD, SIR GEORGE (1782-1855), brother of the preceding, was born in 1782. He was educated at the Charterhouse. In 1808 he received an appointment in the commissariat of the British army in the Peninsula, where he was a witness of many exciting scenes and important battles, of which he gave an interesting account in "Memoirs of an Assistant Commissary-General" attached to the second volume of his *Home Town*, published in 1837. In 1814 he was sent to America to take charge of the commissariat in a naval establishment on the Canadian lakes, and he subsequently held appointments at Halifax and Nova Scotia. Some of his Canadian experiences were narrated by him in *Poor Society and Incidents in the Wilds of North America*, published in 1829. In 1831 he received the honour of knighthood. He published in 1835 *A Home Town through the Manufacturing Districts of England*, and in 1837 a sequel to it, entitled *A Home Town through various parts of the United Kingdom*. Both works are amusing and instructive, but his *Home, a Town of Many Days*, published in 1849, is somewhat dull and tedious. He also contributed several articles to the *Quarterly Review*, and translated *Historical Memoirs of Cardinal Pacca*, 1850, and the *Metamorphoses of Apuleius*, 1861. He died in London, May 2, 1855.

HEARNE, SAMUEL (1745-1799), an English explorer, was born at London in 1745. At the age of eleven he entered the Royal Navy as midshipman in the vessel of Lord Hood, but at the conclusion of the war he took service with the Hudson's Bay Company as quartermaster. In 1768 he was appointed to examine portions of the coast of Hudson's Bay with a view to the improvement of the cod-fishing, when he executed his task with such ability that it was resolved to employ him in the discovery of the north-west passage, and of certain mines of copper whose existence was asserted by the Indians. His first attempt, upon which he set out on November 6, 1769, was unsuccessful owing to the desertion of the Indians, and his second, entered upon on 23d February 1770, was by the breaking of his quadrant likewise rendered abortive, but in his third expedition, upon which he started in December 1770, he was completely successful, as he not only discovered the existence of copper on the banks of what is now known as Coppermine river, but traced the course of that river till it joined the Arctic Ocean. After an absence of eighteen months and twenty-three days he arrived at Fort Churchill, of which he was subsequently promoted to be the governor. He returned to England in 1787, and died there in 1792. An account of his journey from Prince of Wales Fort to the Northern Ocean was published posthumously in 1795.

HEARNE, THOMAS (1678-1795), an English antiquary, was born in 1678 at Littlefield Green, in the parish of White Waltham, Berkshire, where his father, the parish clerk, in payment of the rental of the vicarage house in which he lived, taught ten boys yearly. Thomas, after

receiving the rudiments of education from his father, was sent by the kindness of a gentleman to the free school of Bray, "on purpose to learn the Latin tongue." The gentleman in 1695 took him into his house, and his education was continued at Bray till the Easter of 1696, when he was sent to study at Edmund Hall, Oxford. There his diligence and scholarship attracted the attention of Dr John Mili, the editor of the Greek Testament with various readings, who employed him to compare several MSS. He afterwards took the degree of B.A. in 1699, and on account of the reputation he had acquired for his knowledge of books he was in 1701 appointed assistant-keeper of the Bodleian Library. There at his own option he set himself diligently to correct the catalogue, and prepared an epilogue, which was afterwards incorporated in the new catalogue without acknowledgment. His interest in the antiquarian treasures of the library induced him to refuse many valuable preferments, and in 1713 he was appointed second keeper, with the stipulation made by himself that he should also be junior, so as to obtain access to the library at any time he pleased. In 1714 or 1715 he was elected archi-typographer and esquire in a beadle of civil law in the university, but, an objection being taken to his holding this office along with that of second librarian, he resigned it in the November following. In January 1718 he was compelled, on account of his refusal to take the oath to the Government, to resign also the appointment of librarian, but he continued to reside principally at Oxford, where he occupied himself chiefly in preparing for publication the works of old English authors. His judicious and inappropriate insertion of Jacobite sentiments in his prefaces awakened, however, the hostility of the university magistrates, and subjected him to several prosecutions. He died 10th June 1736. Though Heame was somewhat indiscriminate in his antiquarian taste, and tumbling and desultory in his style of composition, his persevering diligence and minute accuracy enabled him to do valuable service in bibliography.

His publications were nearly all printed by subscription at Oxford. The principal of them are—*Quædam Hæc sunt, Reliquæ Bodleianæ*, an edition of Lapp, Spelman's *Life of Alfred the Great*, *Polinici's Itinerary*, *Polinici's Collections*, *Alia Apostolorum*, *Titus Livii Per Julianum*, *Vita Joannis Quendi*, *Regis Angliæ*, *Alia de Dantiæ Annæ*, *Gulielm. Roperis Vita*, *D. Thomas Mori Erythæ Auctori*, *Gulielm. Camdens Annales Roman Anglicanæ et Hibernicæ*, *Joannis Elshabetti Gulielm. Noddingensis Historiæ*, *Thomas Spelman's A Collection of some Decrees written by Eminent Antiquaries upon English Antiquities*, *Roberti de Arosbury Historiæ in duobus libris*, *Georgii Sædæ in duobus libris*, *Johannis de Fordens Synchronicæ Generum*, *Willelmi et Anthonii de Gloucestria, Roberti de Gloucestria, et Henrici de Gloucestria, et Anthonii de Gloucestria*. Most of these have been reprinted. His MSS were left by him to Dr William Bradford, of whom they were bought by Richard Rawlinson and bequeathed to the Bodleian Library. *Edinburgh: Hæc sunt, Reliquæ Bodleianæ*, the remains of Thomas Heame, of Edmund Hall, being extracts from his MSS data, collected with a few notes by Philip Bliss, was published in two volumes, Oxford, 1867, 2d ed., London, 1869.

See *Imperial Memoirs of the Life and Works of Thomas Heame* M.A., by several hands. London: The Library of the British Museum, 1771, and Nichols's *Literary Anecdotes*. Letters addressed to T. Heame edited by T. Gutter, were privately printed at London, 1771. *Edinburgh: Life of T. Heame*, with notes, notes, in the library of the British Museum.

HEART, DISEASES OF THE, form a large proportion of the most serious disorders that afflict mankind, in youth as well as in advanced life. For the structure and functions of the organ the reader is referred to **ANATOMY** and **PHYSIOLOGY**.

In the early ages of medicine, the absence of correct anatomical, physiological, and pathological knowledge prevented diseases of the heart from being recognized with any certainty during life, and almost entirely precluded them from becoming the objects of medical treatment. But no sooner did Harvey (1628) publish his discovery of the circulation of the blood, and its dependence on the heart

as its central organ, than derangements of the circulation began to be recognized as signs of disease of that central organ. The earliest indications of this important step in the diagnosis of these diseases are to be found in the instructive records contained in the writings of the great pathologists of the beginning of the 18th century, of whom the chief in this respect are Lancisi, Morgagni, Senac, and Meckel. There is, however, a limit to the information obtainable in this way, and, though its range has been largely increased in our day by the invention of such instruments as the phrygmograph and cardiograph, etc., it was very easily exhausted in those early times, when men had only their unaided senses to depend upon, and but little experience to guide them. We need not wonder, then, that after the first great step was taken there was but little further progress made, and medicine had to wait till the beginning of another century, when Corvisart (1806) first made practical use of Auenbrugger's (1761) invention of percussion to determine the size of the heart, enlargement of that organ bulking largely in those days as a substantive disease. Corvisart was also in the habit of listening to the sounds made by the heart, and he may therefore be regarded as the first practical exponent of our modern methods of physical exploration, though scarcely as their founder. Then as Auenbrugger invented percussion, so Laennec (1819) was undoubtedly the first to make a valuable application of mediate auscultation to the diagnosis of diseases of the chest, and it is to him we trace all the benefits derived from this method of inquiry, though it is to Bouilland (1824) that we are chiefly indebted for its extension to the diagnosis of diseases of the heart, while it is to the clinical experience, and above all to the practical experiments, of James Hope (1832) that we owe much of that precision we have now attained in our diagnosis of those diseases from abnormalities in the sounds produced during the cardiac movements, just as we have learned from M. Forget (1851) the doctrine of retro-dilatation, which rightly interpreted is capable of greatly informing us as to the origin and progress of heart disease, and from William Stokes (1854) some instructive views on defective heart power as a cause of certain symptoms simulating disease of the brain, which have proved most valuable and suggestive in the diagnosis of diseases of the heart as well as in their treatment.

The half dozen works just alluded to by no means exhaust the literature of this subject during the past ages, but each of them marks an era, and by their means we may readily trace the progress of cardiac diagnosis during the 180 years intervening between Lancisi and Stokes, but during the twenty odd years that have since elapsed the literature of this subject has become so unusually copious and exhaustive that it would occupy too much space merely to enumerate the authors' names. Fortunately this further development need not concern us here.

As in former so in recent times the progress made in the diagnosis of diseases of the heart has been entirely based on physics and on physiology, and the heart is an organ so situated and so connected as to render it singularly amenable to these methods of investigation. Resting on the diaphragm, and projected against the anterior chest wall, the heart is partly within reach, and is otherwise so completely surrounded on three sides by resonant organs (the lungs) that any change in its position or in its size is readily made out by palpation and percussion, while by listening over the cardiac area—auscultation—we can ascertain whether the valves of the heart remain intact, have an unusual strain thrown upon them, or have been rendered incompetent by disease.

As the four openings of the heart lie so close together that a superficial area of half a square inch includes a part

of each, it is only by taking advantage of certain well-known laws regulating the conduction of sound that we are able to differentiate the sounds produced at each of these openings respectively, and to assign to each a definite position on the chest wall, where it is heard at its maximum intensity. Physiology, on the other hand, teaches us that each individual cardiac pulsation, the time of which is marked for us by that impulse against the chest wall of which we are all more or less conscious, consists of alternate acts of contraction and dilatation affecting the four cavities of the heart. Some of these acts precede this impulse, some accompany it, and others follow it, and the relation of any sound produced within the heart to these physiological acts is termed its rhythm.

The functional perfection of the heart is thus easily determined by ascertaining that it is of a normal size, that its impulse is neither too strong nor too weak, and that its sounds are normal when listened to, each in its own position of maximum intensity. When these conditions are present, any abnormal cardiac phenomena, such as palpitation, irregular action, &c., are to be regarded as entirely due to abnormal innervation, and not to any actual disease of the heart. On the other hand functional imperfection is readily detected by the occurrence of any abnormality in the phenomena already referred to, especially if accompanied by a blowing sound instead of the usual valve sound in any of the normal auscultatory areas. And an intelligent appreciation of these facts, together with a correlation of the physical with the physiological phenomena, that is, a correct determination of the rhythm of the sounds heard, enables us to ascertain with certainty, not only the valve implicated, but also the mode in which the lesion has affected or is likely to affect the heart and, through it, the circulation. Having found the heart to be functionally imperfect, we have two alternatives presented to us—either the valves are actually deformed from previous disease, or they are merely functionally imperfect from over distention of the cardiac cavities, a state of matters which may arise from various causes, and which is always susceptible of great relief and very often of perfect cure.

The great function of the heart is to keep up such a pressure within the arterial section of the vascular canals as will suffice for the maintenance of the circulation and of all the organic functions of the body dependent upon it. The tendency, however, of all the extrinsic forces connected with the circulation is to equalize the blood pressure throughout the vascular system, and so to bring the circulation to a stand-still, and indeed it is in this way that death at last occurs, whether it happen suddenly or slowly the cause is still the same—cessation of the circulation brought about by equalization of the blood pressure throughout the whole of the vascular system, or, as it may be otherwise put, from decline of the arterial (aortic) blood pressure.

Valvular lesions of the heart, however produced, tend, as may be readily understood, to neutralize the cardiac function and to lower the arterial blood pressure, either by permitting an unnatural escape of the blood backward (regurgitation) or by obstructing its onward flow (obstruction). And this action is further intensified by the interference with the cardiac nutrition which necessarily results, first of all directly, from the heart being flushed with blood at a low pressure, and secondly indirectly, from the imperfect performance of all those functions, such as digestion, &c., upon which the formation of healthy blood depends, arising from the same cause.

Valvular disease thus gives the heart more work to do, while it takes from it the power of doing it, putting the organ in a vicious circle. In this way curable disease if neglected may easily lapse into incurability, while in incurable disease there can be but one ending, though, apart

from such accidents as embolism or asystole from violent emotion or exertion, that is, neither so sudden nor so speedy as is commonly supposed, and indeed usually occurs from gradual action, often accompanied by dyspnea, and preceded by a life of more or less active exertion, averaging in many cases not less than twenty years from the primary onset of the disease. During this comparatively long period the disease may have been entirely mute, that is, the valve lesion has progressed so slowly from its tugging commencement that the residual accumulation in the cavity primarily affected has gone on *guttatim*, and has spent itself lackadaisically over the other sections of the circulation in the same gradual manner, the resulting dilatation being so gradually followed by compensating hypertrophy that the sufferer has never been aware of any derangement of his functions. A time comes at last, however, when, from a failure of nutrition due to physical causes, the increase in the heart's bulk ceases to be muscular, it becomes fibrous, then indeed the diaphragm is no longer mute, serious rupture of the compensation sets in, and all that can do is to make the inevitable declension as gradual as possible. Up to this period any accidental rupture of the compensation, which readily enough occurs from over exertion, imperfect nutrition from any cause, or from any febrile attack, is at first perfectly amenable to appropriate treatment, though the residual compensation is always less stable than it had been previously.

Baptized compensation is often attended by very alarming symptoms, such as great general droop and extreme irregularity of the heart's action, but the true measure of the patient's danger lies less in these symptoms than in the condition of the cardiac muscle, and in the circumstances which threaten asystole, that is, arrest of the heart's action.

If in early times the diagnosis of diseases of the heart was a matter of great difficulty, this seemed of less importance as that treatment was so infelicitous that it scarcely penetrated, says Senac, "dans les maladies du cœur, la médecine paraît plus stérile, que peut-on espérer des médicaments, par exemple, dans les dilatations du cœur?" But modern science, which has rendered the heart so accessible from all sides that there is nowadays probably no organ of the body whose diseases can be so readily detected or so accurately discriminated, has not only pointed out the true source of danger in these diseases, but has also put into our hands a remedy by which some are cured who were formerly thought incurable, and as a result we acquire here these downward progress so successfully arrested that they feel themselves to be practically cured. And yet DIGITALIS (q v) was all but unknown 100 years ago, while so little was known of its real action—*atto medicum*—that within the last thirty years a living author wrote that the use of digitalis as a diuretic in heart disease was quite "indefensible," as "the failing heart is absolutely incapable of sustaining the depressing influence of the drug." Nowadays we know digitalis to be the only drug that can be relied on for increasing the power of the heart's contractions, and it also slows them, the result being that the blood pressure is increased throughout the whole arterial system, and that, time being given for the heart itself to be flushed by blood at an increased pressure, its nutrition is improved. The heart not only acts more powerfully under the immediate influence of the drug, but it becomes more able to act, so that by and by the drug may be left off, though indeed, should the muscular degeneration determinately threaten a rapid progression, tonic doses of the drug may be safely given daily for many years continuously, in spite of all our forebodings creaking as to the dangers of accumulation. But however much allows the effects of tonic doses of digitalis may be, the virtues of the drug in larger doses are even more wonderful in appropriate cases, for by means of large doses the skilled physician has it in his power

permanently to contract many dilated hearts, and so to cure what seemed an incurable disease not only to Sane but even to many of his more modern successors.

There are many other drugs employed in the treatment of diseases of the heart, but there is no other deserving of special mention. Other medicines are employed to relieve pain, aid digestion, dispel flatulence, unload the bowels, improve the blood, or simply as general tonics, and may be catalogued as nuxipha, chloroform, belladonna, peysane, arsenoid, aloes, rhubarb, iron, &c.

ANGINA PECTORIS (*p*) is a painful disease of the heart which has already been described. *Palpitation* is an extremely rapid and sometimes forcible action of the heart. *Intermittent* and *Irregular Action* are sufficiently described by their names, irregular action may be tumultuous or so peculiar as to denote the name of a venial *debilitas cordis*, intermission consists in the dropping of a beat every second, third, or fourth time, or seldom. Sometimes the intermission only applies to the pulse, the heart acting regularly, and is caused by that particular systole not being forcible enough to propel the blood to the periphery, occasionally we have two beats of the pulse and then an intermission, constituting what has been termed a *pulsus bigeminus*, or the rhythm of the intermission may be even more varied. All those forms of perverted action of the heart may accompany valvular lesions, or they may occur in hearts whose valves are sound, the walls of such hearts are, however, almost invariably more or less feeble, imperfectly nourished, and the blood often poor and watery. They are rarely indicative of any real danger, though sufficiently troublesome and alarming to the sufferer, they arise from abnormal innervation, and are part of the penalties we pay for our present state of organization. We could enjoy nothing if we could not also suffer, and the bluish of sensitiveness, the quickened pulse of affection, are paid for by the throbs of anxiety, and the fatal inhibition of the heart's action due to overwhelming emotion. Most of these cases, however, own a much more ignoble origin, a debilitated distention of the stomach, a cramp-like dyspnoea, the abuse of alcohol and tobacco, &c., are frequent sources of nervous heart trouble, so frequent that in some parts where young men most do congregate the tobacco heart

especially is quite a proverbial ailment. Overwork, worry, or excess of any kind is sufficient to bring on heart trouble of this character, as we can readily understand when we reflect that the heart does about one-fifth of the whole mechanical work of the body—a work equivalent to raising its own weight over 13,000 feet an hour, that it takes its rest only in short snatches as it were, its action as a whole being continuous, and that it must necessarily be the earliest sufferer from any improvidence as regards nutrition, mental emotion being in this respect quite as potential a cause of constitutional bankruptcy as the most violent muscular exertion. Fortunately, to a skilled physician there is no difficulty of determining the true nature of these cases, and they are all more or less amenable to appropriate treatment. *Syncope*, or fainting, is an affection somewhat similar to those just described, it essentially consists in an emotional inhibition of the cardiac systole, so that the blood pressure within the brain falls below that necessary for the maintenance of consciousness, as the heart's action fortunately does not in these cases entirely cease, the best plan is to favour the flow of blood to the head by maintaining the sufferer with a lowered and slightly depending head until the effects of the momentary inhibition have passed off. The inflammatory affections of the heart, *Carditis*, *Endocarditis*, and *Pericarditis* are most important and serious affections, but their history and treatment are more suited for a work on practice of physic, in any of which full information regarding them may be found. They are mainly rheumatic and gouty in character, and they are to be regarded as varieties of these diseases, the mere fact of their affecting the heart is of but little consequence as to their immediate result, however important it may be and by become from the valvular lesions to which they so often give rise. There are but few exceptions to this rule, and amongst them are those rare cases in which acute endocarditis blocks the coronary vessels and gives rise to fatal angina. *Fatty Degeneration* of the heart, which bulks so largely in the popular mind as a cause of sudden death, is an almost hypothetical lesion of most infrequent occurrence, probably never found apart from disease of the coronary arteries, impossible of diagnosis, and very rarely of itself proving suddenly fatal. (A W B)

H E A T

By SIR WILLIAM THOMSON

Read at a meeting of the Act of Parliament of Canada, in the year 1880, by WILLIAM THOMSON, Esq., Glasgow, Scotland, on the office of the Minister of Agriculture

H EAT is a property of matter which first became known to us by the aid of very distinct senses

1. *Sense of Heat*—The sense of touch, as commonly met with, has two distinct objects—force and heat. If a person establishes out his hand till it meets anything solid, or holds it out while something solid is placed upon it, he experiences a sensation of force. He perceives resistance to the previous motion of his hand in one case, in the other case the necessity of resisting to prevent his hand from being forced downwards, the immediate object of this perception in each case is force¹. But there is another very distinct sensation, that of heat or cold, which he may or may not

¹ The sense of smoothness, and toughness, to which physiologists have sometimes given the special name "tactile sense" is as clearly a sense of force as is what they call the muscular sense. The sense of touch next is a sense of force at places of application distributed over the skin of the finger, while in the muscular sense of force the place of application on a finger is distinguished by the position of the hand perceiving the force. The internal mechanism of sense and nerve in one case and that of muscles in the other, through which the perception of places of application of force is obtained, are no doubt different, but the thing perceived is essentially the same—force—the complete determination of the nerves involves magnitude of the force, its place of application, and its direction.

perceive in either of those cases, and which he may also perceive, still by what is commonly called the sense of touch, in other cases even when no sense of force is also experienced. Thus, in the first case, if the solid be a fixed can of warm water, or of cold water, the person perceives a sense of heat or of cold, and, supposing him to have performed the operation with his eyes shut, his mind is informed by the double sense of touch that his hand has met with a hot fixed body or a cold fixed body, in the other case he may perceive that a hot heavy solid, or a cold heavy solid, has been laid upon his hand. But if he dips his hand gently into a can of water, or if he holds it towards a fire, or if he exposes it to a gentle current of air, or waves it about through the air, he perceives heat or cold without any accompanying sense of force.

The earliest scientific thoughts respecting these sensations of heat and cold must have led to the true conclusion that the sense of some property of external matter on which the sensations depend, and a little advance on the natural philosophy of the subject has suggested and proved that this property is also possessed by the living body, and that the sensation of heat or cold in the hand, in the instances

referred to above, depends on the change produced in the hand in respect to this property by a change of circumstances which preceded the sensation. We now call heat the property of matter concerned in these sensations, and temperature a certain variable quality of matter varying according to its temporary condition in respect to heat.

In the slightest modern scientific language (compare § 3 below) the word heat is used to denote something communicable from one body or piece of matter to another, and temperature a definite variable quality of matter, varying generally in any particular piece of matter when heat is communicated to it or taken from it, varying also as we shall see (§§ 8 and 9 below, also THERMODYNAMICS) in consequence of operations which can take place within the body itself, or which may be performed upon it from without, but which cannot be described as communication of heat to it or drawing off of heat from it.

§ 2 *Latent Heat*.—There are exceptional cases in which temperature does not vary in a mass of matter when heat is communicated to it from, or taken from it to, external matter. For instance, when the body is ice at the melting point, heat communicated to it does not raise its temperature, or if the body be water at the freezing point with ever so small a piece of ice in it (see MITTET, PROPERTIES OF), heat taken from it does not cause its temperature to fall, or if the whole mass considered be ice and water well mixed, heat may either communicate to it or taken from it without altering its temperature, or if the body be water at the boiling point in the open air, heat very slowly communicated to it in however great quantities does not raise its temperature sensibly, but causes it to disappear by evaporation from its surface, or if the body be steam in a cylinder with a little water in the bottom and with a frictionless piston above it for roof (fig. 1), under atmospheric pressure, heat taken from it very slowly does not cool it until the whole steam has become condensed into water, and heat communicated to it very slowly does not warm it until the whole water has become evaporated into steam, or if the body be ice (or frozen water), in place of the liquid water of the last case, and if the pressure on the upper side of the piston, instead of atmospheric pressure of about 1033 grammes per square centimetre (14.7 lb per square inch), be anything less than $\frac{1}{10}$ of a gramme per square centimetre, the same statement will still apply with "ice" substituted for water.

Fig. 1

Black's celebrated doctrine of latent heat is merely the declaration of a class of phenomena of which the preceding illustrations sufficiently indicate the character. Modern mysticism has been much exercised in respect to the terms sensible heat and latent heat, whether in denying them, or in continuing to use them, but with aggravating haziness, instead of the clear wrongness of the old doctrine. It has become of late years somewhat the fashion to decry the designation of latent heat, because it had been very often stated in language involving the assumption of the materiality of heat.¹ Now that we know heat to be a mode of motion, and not a

material substance, the old "impressive, clear, and wrong" statements regarding latent heat, evolution and absorption of heat by compression, specific heats of bodies, and quantities of heat possessed by them, are summarily discarded. But they have not yet been generally enough followed by equally clear and concise statements of what we now know to be the truth. A combination of impressions surviving from the old erroneous notions regarding the nature of heat with imperfectly developed apprehension of the new theory has somewhat liberally perplexed the modern student of the thermodynamics with questions unanswerable by theory or experiment, and propositions which escape the merit of being false by having no assignable meaning. There is no occasion to give up either "sensible heat" or "latent heat", and there is a positive need to retain the term latent heat, because if it were given up a term would be needed to replace it, and it seems impossible to invent a better. Heat given to a substance and warming it is said to be sensible in the substance. Heat given to a substance and not warming it is said to become latent. Those designations express with perfect clearness the relation of certain material phenomena to our sensory perception of them. Thus when heat given to a quantity of water warms it, the heat becomes sensible to a hand held in the water. When a basin of warm water and a basin of water and ice are placed side by side, a hand dipped first in one and then in the other perceives the heat. If now the warm water be poured into the basin of ice and water, and stirred for a few seconds of time (unless there is enough of warm water to melt all the ice), the hand perceives no warmth, on the contrary, it perceives that the temperature is the same as it was in the basin of ice and water at the beginning. Thus the heat which was sensible in the basin of warm water has ceased to be sensible in the water that was in that basin, and has not become sensible in the other. It is therefore well and to have become latent.

CALORIMETRY

§ 3 *Calorimetry by Latent Heat*.—The doctrine of latent heat leads us very smoothly to a most important measurement in thermal science, the measurement of quantities of this wonderful property of matter which we call heat, and thus without our knowing anything of what the nature of heat is, whether it be a subtle elastic fluid, or a state of motion, or possibly some modification of matter related to action of force. Without, in the first place, admitting into our minds any definite idea as to the nature of heat, we may agree to measure quantities of heat by quantities of ice melted into water without change of temperature. Thus if a kilogramme of ice is melted by a large quantity of water at a lukewarm temperature, or by a comparatively small quantity of very hot water, the same quantity of heat has certainly gone from the warm water to the ice in each case, supposing that the result in each case is the ice and warm water left all in a state of ice-cold water. The measurement of quantities of heat, whether thus by the melting of ice, or by any other means, received the name of "Calorimetry," when the essence of heat was supposed to be a fluid, and thus fluid called caloric. The name calorimetry is still by general consent retained to designate measurement of quantities of heat, as distinguished from thermometry, or

¹ A hundred years ago these deeper philosophers who in their judgment anticipated, or tried to anticipate, what we now know to be the true theory of the nature of heat, had indeed good grounds to be jealous of even the phrase latent heat. Maxwell says—"It is worthy of remark that Fahrenheit, though one of the greatest chemical discoverers of his time, would not accept the phrase latent heat. He refused to speak of the generation of heat when steam is condensed, a phrase inconsistent with the notion that heat is matter, and objects to Black's term as relating 'to a hypothesis depending on the supposition that the heat of bodies is owing to their containing more or less

of a substance called the matter of heat, and, as I think Sir Isaac Newton's opinion that heat consists in the internal motion of the particles of bodies much the most probable, I chose to use the expression heat is generated" (*Phil. Trans.*, 1758, quoted by Forbes). We shall not now be in danger of any error if we use latent heat as an expression meaning neither more nor less than this.

² DEFINITION.—Latent heat is the quantity of heat which must be communicated to a body in a given state in order to convert it into another state without changing its temperature.—"Maxwell's Theory of Heat," pp. 72, 73.

the measurement of temperature (§ 10-87). As long as the truth or falsity of the materialistic hypothesis seemed an open question, the word calorie was held to imply the materiality of heat. Thus Davy, after discussing some of the fundamental dogmas of the "Calorists," as he called them, and describing his own experiments which proved beyond all doubt the falsity of their fundamental hypothesis that heat is matter, varied the statement of his conclusion by saying, "or caloric does not exist." While accepting Davy's conclusion, however, we need not accept this way of stating it, and as most of our best modern writers still use the word caloricity, and as French writers have, in comparatively recent times, introduced the word "calorie" to designate a unit quantity of heat, it is decidedly convenient still to retain the name caloric to denote definitely the measurable essence of heat. This is convenient scientifically in tending to give precision to language and ideas respecting the two classes of measurement, caloricity and thermicity, and it has the advantage of leaving the more popular word heat available for that sometimes less general use, from which we cannot altogether displace it, in which it may sometimes mean high temperature, as when we speak of great heat, or summer heat, or blood heat, sometimes a measurable quantity of heat, as in the term latent heat, and sometimes a branch of study or science dealing with the transmission of heat by conduction and radiation, as in the title of Fourier's great work *Théorie analytique de la Chaleur*, or the whole province of science connected with heat, including caloricity and thermicity, and conduction and radiation of heat, and generation of heat, and dynamical relations of heat, as in English titles of separate books such as Dulong's, Dufour Stewart's, and Maxwell's, or of chapters or divisions of larger treatises, such as even the present article.

§ 4. *Caloricity by Melting of Ice*—Caloricity was first first retained by means of the melting of ice as explained above, and the first thermal unit, or unit quantity of heat, or "caloric," although not then called caloric, was the quantity of heat required to melt unit weight of ice. Thus, for example, is the unit on which Fourier founds his reckoning illustratively when he explains the fundamental principles of his theory of the conduction of heat. Ice seems to have been first used for caloricity by Willeke, a Swede. For the systematic application of this method for the measurement or quantities of heat in various physical inquiries Laplace and Lavoisier constructed an instrument, the first to which the name of calorimeter was applied, and described it in the memoirs of the French Academy of Sciences for 1780.¹ Though in the hands of Laplace and Lavoisier it gave good results, it had a great inconvenience, which with less careful and less scientific experimenters might lead to great inaccuracies, on account of the water adhering by capillary attraction to the broken ice, instead of draining away from it completely and showing exactly how much ice had been melted. To avoid this evil Sir John Herschel suggested that, instead of draining away the water from the ice, the water and ice should all be kept together, and the whole bulk measured. The diminution of bulk of the whole thus gives an accurate measurement of the quantity of ice melted, because ice melting into water comes to occupy just 91.675 per cent of its original volume. This suggestion is admirably carried out by Bunsen's burner in his ice calorimeter, an instrument possessing also other novel features of remarkable beauty and scientific interest. It is particularly valuable for the measurement

of small quantities of heat. Its inventor, for example, by means of it succeeded in making satisfactory determinations of the specific heat of some of those rare metals, such as indium, of which only a few grammes have been obtained.

§ 5. *Caloricity by the Evaporation of Water*—By another application of Black's doctrine of latent heat, the evaporation of water may be used for caloricity with great advantage in many scientific investigations. It is used generally in engineering practice, particularly for testing the heating power of different qualities of coal and the economy of various forms of furnaces. The thermal unit, which presents itself naturally in this system, is the quantity of heat required to evaporate unit weight of water when the pressure of the atmosphere is measured by the barometric in some conventional standard amount, such as that called one atmosphere, or one atmo, being that for which the barometer, with its mercury column at zero centigrade (or the temperature at which ice melts), stands at 76 centimetres in the latitude of Paris, 48° 50', or at

$$76 \times (1 - 0.0031 \sin^2 48^\circ 50') \\ = 1 - 0.0031 \sin^2 48^\circ 50'$$

in any latitude l . This thermal unit (see THERMODYNAMICS), according to Regnault's observations, equal to 6.8 times the ice caloricity unit.

§ 6. *Thermometric Caloricity*—The most prevalent mode of caloricity in scientific investigation has been hitherto, however, neither that by the melting of ice, nor that by evaporation of water, nor indeed anything founded on the doctrine of latent heat at all. It has been founded on the elevation of temperature produced in water by the communication to it of the heat to be measured, and, for the sake of distinction from caloricity by latent heat or otherwise, it may be called thermometric caloricity. We can only consider it now in anticipation, as we have not yet reached the foundation of any thermometric scale, but even now we can see that, in any way we fix upon any two particular determinate temperatures, the quantity of water warmed from the lower to the higher of them by the heat to be measured is a perfectly definite measure for the quantity of this heat. The two temperatures chosen for thermometric caloricity are those marked 0° and 1° on the centigrade scale. The first of these we can understand at present, being the temperature at which ice melts under ordinary atmospheric pressure. The second is fully defined in §§ 35, 37, 61, 67. The quantity of heat required to raise unit mass of water (1 kilogramme, or 1 gramme, or 1 milligramme, or 1 lb, as the case may be) from zero to 1° C is called the thermal unit centigrade, and sometimes, especially by French writers, the "calorie."

§ 7. *Comparison of Caloricity to Units*—Observations by Prevost and Desmurs, and by Regnault, on the latent heat of fusion of ice, show it to be 79.25 thermal units centigrade, a result differing but little from Black's original determination, which made it 143 thermal units Fahr.—thus being equal to 78.9 thermal units centigrade. Thus if one kilogramme of ice be put into 79½ kilogrammes of water at 1° C., and left till the whole is melted (the process may be accelerated by not too violent stirring, § 9), the result will be 80½ kilogrammes of water at 0° C.

Regnault's experiments on the latent heat of steam show that the quantity of heat required to convert into steam unit

* This is chosen because all the most accurate experimental determinations depending on a conventional standard for atmospheric pressure, such as measurements of thermal expansions and specific heats of gases, of latent heat of melting solids in terms of a caloricity unit depending on the centigrade thermometric scale, of latent heats of vapours, and thermal expansions of mercury and glass, and comparisons of mercury and air thermometers, are those of Regnault, and were made in Paris and calculated and given to the world according to an absolute standard atmosphere corresponding to 76 centimetres of mercury there.

¹ The instrument itself is preserved in the *Conservatoire des Arts et Métiers* in Paris. It is described and explained in Maxwell's *Theory of Heat*, chap. vi.

Bunsen's ice calorimeter.

mass of water at the boiling temperature, under standard atmospheric pressure (§ 5), is 5338 thermal units centigrade. This number, which is no doubt very accurate, differs but little from Watt's final result, 960 thermal units Fahrenheit (equal to 533.8 thermal units centigrade), obtained by him, in a repetition in 1781 of experiments which he had commenced in 1765 at the invitation of Black, whose pupil he was.

§ 8 *Preliminary regarding the Nature of Heat*—*Dynamical Calorimetry*—From the dawn of science till the close of last century two rival hypotheses had been entertained regarding the nature of heat, each with more or less of plausibility but neither on any sure experimental basis—one that heat consisted of a subtle elastic fluid permeating through the pores or interstices among the particles of matter, like water in a sponge, the other that it was an inextinguishable commotion among the particles or molecules of matter. In the year 1799 Davy, in his first published work entitled *An Essay on Heat, Light, and Combinations of Light*,¹ conclusively overthrew the former of these hypotheses, and gave good reason for accepting as true the latter, by his celebrated experiment of converting ice into water by rubbing two pieces of ice together, without communicating any heat from surrounding matter. A few years earlier Rumford had been led to the same conclusion, and had given very convincing evidence of it in his observation of the great amount of heat produced in the process of boring cannon in the military arsenal at Munich, and the experimental investigation on the extinction of heat by friction² with which he followed up that observation. He had not, however, given a perfect logical demonstration of his conclusion, nor even quite a complete experimental basis on which it could be established with absolute certainty. According to the materialistic doctrine it would have been held that the heat excited by the friction was not generated,³ but was produced, squeezed out, or let flow out like honey from a broken honeycomb, from those parts of the solid which were out or broken into small fragments, or rubbed to powder in the frictional process. If this were true, the very small fragments or powder would contain much less heat in them than an equal mass of continuous solid of the same substance as theirs. But unhappily the caloric doctrine, besides its fundamental hypothesis, which we now know to be wrong, had given an absurd and illogical test for quantity of heat in a body, of which a not altogether innocuous influence still survives in our modern name "specific heat," and Rumford actually, in trying to disprove the materialistic doctrine, was baffled by this sophism. That is to say, he measured the specific heat capacity for heat" of the powder, and he found that the powder took as much heat to warm it to a certain degree as did an equal mass of the continuous solid, and from this he concluded that the powder did not contain less heat than the continuous solid at the same temperature. This conclusion is so obviously unwarranted by the premises that it is difficult to imagine how Rumford could have for a moment put forward the "capacity for heat" experiment as proving it, or could have rested in the conclusion without a real proof, or at least the suggestion of a real proof. All that Rumford's argument proved was that the fundamental hypotheses of the "caloricists" and their other altogether gratuitous doctrine of equality of "specific heat" as a test for equality of whole quantities of heat in matter could not be both true, and any one not inclined to give up the

materialistic hypothesis might have cheerfully abandoned the minor doctrine, and remained unmoved by Rumford's argument. If Rumford had but melted a quantity of the powder (or dissolved it in an acid), and compared the heat which it took with that taken by an equal weight of the continuous solid, he would have had no difficulty in proving that the enormous quantity of heat which he had found to be excited by the friction had not been squeezed, or rubbed, or pounded, out of the solid matter, but was really brought into existence, and therefore could not be a material substance. He might even, without experiment, have pointed out that, if the materialistic doctrine were true, it would follow that sufficiently long continued pounding of any solid substance by pestle and mortar, whether by hand or by aid of machinery, would convert it into a marvellous powder possessing one or other of two properties about equally marvellous. Either the smallest quantity of it thrown into an acid would constitute a freezing mixture of unlimited intensity,—the longer it had been pounded, the more intense would be its frigorific effect on being dissolved,—or the powder would be incapable of being warmed by friction, because it had already parted with all the heat which friction could rub out of it. The real effect of Rumford's argument seems to have been to save the intellectual consciences of those who were not inclined to give up the materialistic doctrine, and to save them from the trouble of reading through Rumford's paper and thinking for themselves, by which they would have seen that his philosophy was better than his logic, and would inevitably have been forced to agree with him in his conclusion. It is remarkable that Davy's logic, too, was at fault, and on just the same point as Rumford's, but with even more transparently logical fallaciousness, because his argument is put in a more definitely logical form.

"Let heat be considered as matter, and let it be granted that the temperature of bodies cannot be increased unless the matter is diminished from some cause, a heat added to them from some bodies in contact."⁴

"Experiment II.—I procured two parallelepipedons of ice, of the temperature of 20°, 6 inches long, 2 wide, and $\frac{1}{2}$ of an inch thick, they were fastened by wires to the base of iron. By a peculiar mechanism their surfaces were placed in contact and kept in a continued and violent friction for some minutes. They were almost entirely converted into water, which water was collected and its temperature ascertained to be 86° after remaining in an atmosphere of a lower temperature for some minutes. The fusion took place only at the plane of contact of the two pieces of ice, and no bodies were in friction with ice. From time to time new experiments were made, in which ice was converted into water, and, according to the supposition, its capacity is diminished, but it is a well known fact that the capacity of water for heat is much greater than that of ice, and we must have an absolute quantity of heat added to it before it can be converted into water. Friction consequently does not diminish the capacities of bodies for heat."—Davy's *Essay on Heat, Light, and Combinations of Light*, pp. 10-12.

[Deletes from "and, according to the supposition," to "greater than that of ice" inclusive, and delete the lame and impotent conclusion stated in the last eleven words. The remainder constitutes an unanswerable demonstration of Davy's negative proposition that heat is not matter.]

§ 9 *Joule's Dynamical Equivalent of Heat*—It is remarkable that, while Davy's experiment alone sufficed to overthrow the hypothesis that heat is matter, and Rumford's, with the addition of just a little consideration of its relation to possibilities or probabilities of inevitable alternatives, did the same, fifty years passed before the scientific world became converted to their conclusion,—a remarkable instance of the tremendous efficiency of bad logic in confounding public opinion and obstructing true philosophic thought.

⁴ "The result of the experiment is the same if we say, talow, steam, or any substance fusible at a low temperature be used, even if may be fused by collision, as is evident" by the first experiment."

Joule's great experiments from 1840 to 1849, creating new provinces of science in the thermodynamic of electricity, and magnetism, and electro-chemistry, called attention to Davy and Rumford's doctrine regarding the nature of heat, and supplied several fresh proofs, such like Davy's absolutely in itself complete and cogent, that heat is not a material substance, and each advancing with exact dynamical measurement on the way pointed out by Rumford in his measurement of the quantity of heat generated in a certain time by the action of two hammers not urged to overwork themselves. The full conversion of the scientific world to the kinetic theory of heat took place about the middle of this century, and was no doubt an immediate consequence of Joule's work, although Rumford and Davy's demonstrative experiments, and the ingenious and penetrating speculations of Mohr, and Seguin, and Mayer, and the experimental thermodynamic measurements of Colding, all no doubt contributed to the result. Each of the several subjects of thermodynamic measurement undertaken by Joule gave him a means of estimating the quantity of work required to generate a certain quantity of heat, but after several years of trials he was led to prefer to all others the direct method of simply stirring a quantity of water by a paddle, and measuring the quantity of heat produced by a measured quantity of work, and this method he has accordingly used in all his experiments on the mechanical equivalent of the "dynamical equivalent of heat" from the year 1845 to the present time. By this he found his final result of 1849,² which was 772 Manchester foot pounds for the quantity of work required to warm by 1° Fahr, a lb of water weighed in vacuum. In 1870 he commenced work for a fresh determination of the dynamical equivalent of heat at the request of the British Association, and the result was communicated to the Royal Society³ about the end of 1877, with the following preface:

"The committee of the British Association on studies of electricity, having judged it desirable that a fresh determination of the mechanical equivalent of heat should be made by observing the thermal effects due to the transmission of electrical currents

through resistances measured by the unit they had issued, I made such experiments with this view, resulting in a large figure (782.6, *Lab. Assoc. Report*, Dundee, 1867, p. 522) than that which I had obtained by the friction of fluids (772.6, *Phil. Trans.*, 1860, p. 82).

"The only way to account for this discrepancy was to admit the existence of error either in my thermal experiments or in the unit of resistance. A committee, consisting of Sir William Thomson, Professor P. G. Tait, Professor Clerk Maxwell, Professor B. Stewart, and myself, was appointed at the meeting of the British Association in 1870, and with the funds thus placed at my disposal I was charged with the present investigation, for the purpose of giving greater accuracy to the results of the direct method."

The result of this final investigation of Joule's is 772.43 Manchester foot pounds for the quantity of heat required to warm from 60° to 61° Fahr, a pound of water weighed in vacuum, which is about $\frac{1}{10}$ per cent greater than the final result of 1849 expressed in the same terms. According to Regnault's measurements¹ of the thermal capacity of water at different temperatures from 0° to 230° C, it must be about 0.01 per cent greater at 60° Fahr than at 32°.

According to this, Joule's thermodynamic result would be 771.81 Manchester foot pounds, for the work required to warm a pound of water from 60° to 61° Fahr, or 1859.26 *man* 1859.26 feet to metres, we have 423.437 metres. At Paris the force of gravity is about $\frac{1}{10}$ per cent less than in Manchester. Hence for about the middle of France and the southern latitudes of Germany, Joule's result, according to the ordinary reckoning of French and German engineers, may be stated as 423.5 kilogramme metres for the amount of work required to warm 1 kilogramme of water from 0° to 1° C. The force of gravity at Manchester is 981.84 dynes (centimetres per second per second). Multiplying 123.437 by this, we find accordingly 41,053.00 centimetres dynes, or "ergs," for the amount of work in C.G.S. measure required to warm 1 gramme of water from 0° to 1° C.

THERMODYNAMICS

§ 10 *Preliminary for Thermodynamics—Sense of Heat* (resumed from § 1)—The sense of heat and cold is not simply dependent on the temperature of the body touched. If a person takes a piece of iron, or a stone, or a piece of wood, or a ball of wrosted, or a quantity of finely carded cotton-wool, or of eider down, in his hand, or touches an iron column, or a stone wall, or a wooden beam, or a mass of wool or of down, he will perceive the iron cold, the stone cold, but less cold than the iron, the wood but slightly cold—much less cold than the stone, the wool or down decidedly warm.

We now know that if all the bodies before being touched were next one another in similar exposure, they must have been at the same temperature, and from the iron and stone being felt cold we know that this mean temperature is lower than the temperature of the hand. Each of the bodies touched must at the first instant have taken some heat from the hand, and therefore, if the perception was quick enough, all at the very instant of being touched would have seemed cold to the sense. The iron by its high thermal conductivity (§§ 76, 78, 80) keeps drawing off heat from the hand and lowering its temperature, till after many seconds of time an approximately permanent temperature is reached, which may be considerably lower than the temperature of the hand before contact, but somewhat higher than the previous temperature of the iron, because of the internal forces (see THERMODYNAMICS) generating heat in the hand. A similar result, but in less time and with less ultimate lowering of temperature of the hand, takes place when stone is touched. When wood is touched its comparatively small conductivity (§ 76) allows its surface to be warmed again after the first few seconds, sometimes to a higher tem-

¹ *Relation des Experiences*, vol. 1, p. 748, Paris, 1847.

perature than that of the hand before contact, and thus, if the sensation could be perfectly remembered, it would be perceived that the wood was first felt to be cold, and afterwards to be warm. This latter warmth is rendered very perceptible by first holding the hand in contact with a piece of wood, as for instance a mahogany table, for a considerable time, half a minute or more, and then suddenly removing it; a sense of cold is immediately perceived in consequence of the exposure of the hand to the air. The foot is similarly sensitive. If, after holding a bare foot for some time in the air, it be placed on a varnished wooden floor, the floor is perceived to be cold, and if, after standing some time with it pressed to the floor, the foot be suddenly lifted, the air now seems cold by contrast. If a person walks with bare feet on a wooden floor, a continued sense of cold is experienced, and if, immediately after doing so, he sits down, and holds his feet in the air, the air seems to be warm by contrast. The same sensations are perceived even on a carpeted floor, but much less markedly than on a plain wooden floor, and much less markedly on a plain wooden floor than on a varnished wooden floor, and much less markedly on a varnished wooden floor than on a stone floor. In the case of touching soft wool, or finely carded cotton-wool, or eider down, the first instantaneous sensation of cold is scarcely if at all perceived, and that which first provokes consciousness is the subsequent heating, and it is very startling to find a body which we know to be so cold on a frosty day feeling positively warm to the first consciously perceptible sensation after it is touched. In this case the small thermal conductivity or great thermal resistance of the substance is such that heat is carried off by it from the hand slower than it was carried off by radiation and aerial convection (§§ 70, 71) before contact, and thus, after the first momentary cooling of the hand by the initial extraction of heat from it to the cold body touched, in a small fraction of a second of time a higher temperature is attained by the hand than it had before contact.

§ 11 *Sense of Temperature*—The sense of heat is in reality somewhat delicate the real test when properly used. Even an unskilled hand after repeatedly dipped into two beams of water will, as we have found by experiment, detect a difference of temperature of less than a quarter of a degree centigrade, and there can be no doubt that bath and hospital attendants, and persons occupied with hot liquors in various manufactures, such as dyeing, can detect much smaller differences of temperature than that, and, what is still more remarkable, can remember permanently sensations of absolute temperature sufficiently to tell within less than a degree centigrade that the temperature of a bath, or a pontice, or dyeing liquor is "blood heat," or "fever heat," or some other definite temperature to which they have become accustomed.

§ 12 *The method by Sense of Heat—such arbitrary Centigrade Scale deduced from Mixtures of Hot and Cold Water*—Without knowing anything of the nature of heat we might find a complete system of thermometry on the mixing of hot and cold water with no other thermometer (§ 13) than our sense of heat, if we had but two definite constant temperatures of reference. These in practical thermometry are supplied by the melting-point of ice and the temperature of steam from water boiling in air at a definite pressure (the "atmo" or standard atmosphere, § 5). Thus, suppose perfectly abundant supplies of ice and water and of water at the boiling temperature to be available, and suppose it to be desired to measure the temperature of a liver, or lake, or sea. Take measured quantities of the boiling and of the ice-cold water, and mix them by trial until, tested by the hand, the mixture is found to have the same temperature as that of the mass of water of which the temperature is to be determined. Suppose, for example, the mixture giving the required temperature to consist of 86.6 parts by weight

of ice-cold water, and 13.4 parts by weight of boiling water. An equivalent temperature is 13.4 on a perfectly definite arbitrary scale of thermometry in which the temperature of ice-cold water is called zero, that of boiling water 100, and other temperatures are reckoned according to the law of proportion of mixtures of water in the manner indicated by the example, and defined generally in § 31 below. For temperatures within the range of sensibility of the hand this method would give more accurate results than many common thermometers sold by instrument makers for ordinary popular purposes. It may be relied upon for absolute accuracy within $\frac{1}{100}$ ths of a degree centigrade, provided the mixing of hot and cold water is performed with sufficiently large quantities of water, and with all proper precautions to obtain in that part of the process all the accuracy obtainable by the living thermometer.

We shall see (§ 25) that with the most accurate mercury or air thermometer, made for scientific investigation and carefully tested, absolute determinations can scarcely be depended upon within $\frac{1}{10}$ ths of a degree centigrade. The method of mixtures with only the sensory thermometer is not limited to the range of temperature directly perceptible with unimpaired sensibility, but when the temperature to be tested is beyond this range an indirect method must be followed, as thus—

A large quantity of water too warm for the hand is to be tested. Mix it with six times its weight of ice-cold water, thus giving a convenient temperature for the hand, then find by trial what proportions of ice cold and boiling water give a mixture of the same temperature as tested by the hand, suppose these proportions to be 20.2 of boiling water and 79.8 of ice-cold water. The temperature of the mixture is by definition 26.2, and on the same principle the required temperature is three times this, or 78.6.

This system of thermometry is, however, strictly limited to the range between the freezing and boiling points of water, for we do not at present consider the possibilities (see LIQUID, STEAM, MATTER, PROPERTIES OF, THERMODYNAMICS) of obtaining and using thermometric quantities of water below the freezing point and above the boiling point. It is described here, not only because it is very instructive in respect to the principles of thermometry, but because it is in point of fact the thermometric method used through a large range of processes not only in the arts but in scientific investigation. In many cases the hand is a more convenient and easy test than a common mercury thermometer, and it has just about the same sensibility, the commonest thermometers in popular use being in fact scarcely to be read to a quarter of a degree centigrade. In respect to accuracy a common cheap thermometer, though perhaps a degree or two wrong in its absolute indications, may still be used as an accurate indicator of equality of temperatures just as in the hand in the method of mixtures.

In many cases the hand is more convenient than the thermometer, in other cases the thermometer is more convenient than the hand, but in many cases the thermometer is applicable when the hand is not. When the quantities of water tested are abundant, the hand is always the quickest test, but there must be abundance of water to allow it to be satisfactorily and accurately applicable.

THERMOSCOPES DIFFERENTIAL AND INTERMIXING.

Differential Thermoscopes essentially continuous—Intermixture Thermoscopes discontinuous and continuous—Single and Multiple Intermixture Thermoscopes (discontinuous)—Continuous Intermixture Thermoscopes

§ 13 A thermometer is an indicator of temperature. A differential thermometer is a thermometer which shows difference, or tests equality, of simultaneous temperatures in two places. Its action is essentially continuous, de

pending on difference of temperature between the two places, and showing zero continuously when the temperatures of the two places are varied, provided they are kept exactly equal. Every kind of differential thermoscope, and of continuous intrinsic thermoscope, must be founded on some property of matter, continuously varying with the temperature, as density of a fluid under constant pressure, pressure of a fluid in constant volume, volume of the liquid part of a whole mass of liquid and solid kept in constant volume,¹ steam pressure of a solid or liquid,² shape or density of an elastic solid under constant stress, stress of an elastic solid in a constant state of strain, viscosity of a fluid, electric current in a circuit of two metals with their junctions at unequal temperatures, electric resistance of a conductor, in a given moment of a steel or loadstone magnet.

Examples—(1) *Leak's*, differential air thermometer, (§ 99-141 below), (2) steam pressure differential thermoscopes (§§ 99-141 below), (3) *Jenli's* hyd. bulb and piston differential thermoscopes (*American Chem. Soc.*, vol. vi p. 201, *Proc. Am. and Phil. Soc. Manchester*, vol. iii p. 14, *ibid.*, vol. viii p. 32), (4) *Wright's* differential thermoscope (*Philosoph. R. S. E.*, April 5, 1880), (5) thermo-electric differential thermoscopes, (6) *Barnes's* electric resistance differential thermoscopes, (7) *Wright's* viscous differential thermometer (*see Proc. Roy. Soc. E.* for April, 1880).

§ 14. *Intrinsic Thermoscopes*.—An intrinsic thermometer is an instrument capable of indicating one definite temperature or several definite temperatures, or all temperatures within the range of the instrument, whatever it may be—the temperature or temperatures indicated being intrinsically determined by the constitution of the instrument and indicated by some recognizable feature of the instrument which changes discontinuously or continuously, as the case may be, and which is always the same when the instrument is brought back again and again to the same temperature, whatever changes it may have experienced in the mean time. Discontinuous intrinsic thermoscopes show only a limited number of temperatures. A continuous intrinsic thermoscope shows any temperature whatever throughout the range of efficiency of the instrument, ideally any temperature whatever, though in practice every thermoscope is limited, some with both inferior and superior limit, as the mercury thermometer by the freezing of mercury at about -39°C , and the bursting pressure of mercury steam a little above $+380^{\circ}\text{C}$, others with only a superior limit, as metallic thermoscopes, whether thermo-elastic, or thermo-electric, or electric resistance, or thermo-magnetic, by the melting of their substances at very high temperatures, or, in the case of the thermo-magnetic instrument, by the total or partial loss of its magnetism at some temperature much below the melting point of its substance. A continuous intrinsic thermoscope, when applied to a body whose temperature is changing, shows continuously every variation of temperature within its range of efficiency.

§ 15. *Discontinuous Intrinsic Thermoscopes*.—A single intrinsic thermoscope is a thermometer which shows whether the temperature of the body to which it is applied is higher or lower than some one definite temperature depending on the intrinsic quality of the instrument.

Examples—(1) a mass of ice, or of wax, or of fusible metal, (2) an apparatus for boiling water, or other liquid under a perfectly constant pressure, (3) an apparatus for boiling water under the natural atmospheric pressure, and a barometer to measure exactly what the pressure is at the time.

A multiple intrinsic thermoscope might be made by preparing a graduated series of metallic alloys, numbering them in order of their melting points, and arranging them together conveniently for use. The temperature might be reckoned numerically, according to the number of the alloys that melt, when the whole series is exposed to the temperature to be tested. This discontinuous numerical reckoning of temperature is perfectly analogous to the Birmingham

reckoning of wires and sheet metals by numbered gauges. Ideally it may be made infinitely nearly continuous by making a series of alloys with fine enough gradation of composition, but the method is in its essence discontinuous. It is useful for many special applications in science and in the arts, as for instance in that very fundamental one (§ 12) of giving one of the fixed points in the ordinary thermometric scale, the "freezing point", also in a form of safety valve for boilers or hot-water pipes, in which a plug fixed by solder is released by the melting of the solder when the temperature reaches a certain limit, also an exceedingly useful guard against overheating in the fire of a stove, by which a stopper is allowed to fall by the melting of a leaden support, and stop the draught, before the temperature reaches the highest limit judged permissible.

§ 16. *Continuous Intrinsic Thermoscopes*.—Continuity of indication requires, as said above (§ 18), choice of some property or properties of matter varying continuously with temperature, such as those enumerated in § 13. A continuous intrinsic thermoscope must have a feature, depending on the chosen property of matter, which shall vary with perfect continuity when the temperature is gradually changed, and shall always be the same when the instrument is brought to the same temperature again and again, whatever variation of temperature it may have experienced in the mean time. The accuracy of an intrinsic thermometer, whether discontinuous or continuous, depends upon permanence of quality of the material and of the mechanical constitution of the instrument, according to which the recognized features shall always be very accurately the same for the same temperature. The sensibility or delicacy of a continuous intrinsic thermometer depends upon the recognizability of change in its indicating feature with very small change of temperature.

§ 17. The property of matter chosen as the foundation of almost all ordinary continuous intrinsic thermoscopes in common use is interdependence of the density, the temperature, and the pressure of a fluid. The only other thermoscopes which can be said to be in common use at all as "metallic thermometers" (see THERMOMETRY, MATTER, PROPERTIES), these depend upon the change of shape of a rigid elastic solid under a stated stress, or on the change of shape of a compound solid, composed of two elastic solids of different substances melted or soldered together. For the present we confine our attention to the former and much larger class of instruments. The general type of all these instruments, except the steam-pressure thermometer (§§ 59-46 below), is a glass measure, measuring the bulk of a fluid. To give the requisite practical sensibility to the measurement, the glass, except for the case of the constant-pressure gas thermometer (§§ 64-67 below) and of the steam-pressure thermometer, is made of a shape which may be generally described as a bottle with a long narrow neck. The body of the bottle, which may either be spherical or of an elongated form, is called the bulb, and the neck is called the tube or stem (stem we shall most frequently call it, to obviate ambiguities without circumlocutions). The thermometric fluid may be all liquid, as mercury, or oil, or alcohol, or ether, or glycerine and water, or it may be all gas, as common air, or hydrogen, or carbonic acid, or it may be partly liquid and partly steam (steam being a name which we shall invariably use to designate the less dense portion of a fluid substance at one temperature and pressure throughout, and in equilibrium with two pairs of different densities). This last case is different from the two preceding, in respect to the character of the thermometric indication: the whole volume of the thermometric substance may be changed from that of all liquid to that of all steam without changing the temperature or the pressure, and the pressure cannot be changed without changing the

¹ This is the principle of the ordinary mercury or spirit thermometer.

² For definition of steam see § 17 below.

thermo-
meter

temperature, provided the substance is kept in the double condition of part liquid and part steam, or, other words, in this case the pressure depends upon the temperature alone and is independent of the volume. In the steam-pressure thermometer, therefore, there is no debate measuring of volume of the thermometric substance, and the vessel containing it is not in the shape of bulb and stem, but the instrument consists essentially of a means of measuring the pressure of the thermometric substance, with a test that it is really in the twofold condition of part liquid and part steam, whether by seeing it through a glass containing vessel, or by a proper hydraulic appliance for ascertaining that the pressure is not changed by rarefaction or condensation when the temperature is kept constant. Realized thermometers of this species, quite convenient for many practical purposes, with steam of sulphurous acid, of water, and of mercury, to serve for different ranges of temperature, from below -80°C to above $+520^{\circ}\text{C}$, are described in §§ 39-44 below.

§ 18 In respect to general conveniences for large varieties of uses, whether for scientific investigation, or for the arts, or for ordinary life, liquid thermometers are generally and with good reason preferred, but the general preference of either mercury or spirits of wine for the liquid, which is so much the rule, is not (§ 20 below) so clearly reasonable. For ordinary uses in which the thermometer has to be moved about and placed in various positions, gas thermometers are much less convenient, because they require essentially an accurate measurement of pressure, and generally for this purpose a column of liquid. But when the thermometer is to be kept always in one position, as for instance when it is devoted to testing the temperature of the air indoors or out of doors, Amontons' air or gas thermometer is really as convenient and as easily read as any liquid thermometer can be, and even, if simple as it is, involves a triple division of the hermetically sealed space, with three different conditions of occupation,—one part occupied by the thermometric substance, another by the pressure-measuring vapourless liquid,¹ and the third vacuum and it is by so much the less simple than the liquid thermometer that in the liquid thermometer the enclosed space is divided into only two parts, one occupied by the thermometric liquid, and the other by its steam, with

FIG. 2

¹ An instrument closely resembling that shown in the drawing (Fig. 2), but with common air instead of hydrogen, was made for the writer of this article, by Cassell, about fifteen years ago, and has been used for illustrations in the natural philosophy class in Glasgow unvaryingly ever since. It is probably an exceedingly accurate air thermometer. When it was set up in the new lecture room after the migration to its present locality in 1870, the tube above the manometric liquid column was closed at air. To do this the instrument must be held in such a sloping position, with the closed end of the tube down, as to allow the bubble of air always found in it to rise and burst in the bulb. If now the instrument is placed in the upright position, the liquid rushes to leave the top of the tube, and it would remain filling the tube (probably, for ever) if left in that position. No violence of knocking which has been ventured to try to bang it down has succeeded. To bang it down a bubble of air must be introduced. The bubble must be very small, so that the pressure of the air which fills it may become reasonable when this air expands into the space of the tube left above the manometric column after it descends to its proper thermoscopic position. Special experiments made for the article in September 1879 showed

on without some admixture of common air. For accuracy the air or gas thermometer is superior, we might almost say incomparably superior, to the mercury thermometer, and, though in a much less degree, still decidedly superior to even the most accurate liquid thermometer, on account of the imperfect constancy of the glass containing-vessel.

§ 19 If we were quite sure of the bulk measurement given by the glass bulb and tube, liquid thermometers would be quite as accurate as gas thermometers. For there is no difficulty in giving any required degree of sensibility to the instrument by making the bulb large enough, and the quality of the liquid itself, hermetically sealed in glass, may be regarded as being as constant as anything we know of in the material world. But, alas for thermometry, the glass measure is not constant! In fact, glass is a substance of very imperfect elasticity (ELASTICITY, § 4, vol. vii p. 797), and it is found that the bulb of a thermometer is not always of the same volume at the same temperature, but that, on the contrary, it experiences uncertain changes exceedingly embarrassing in thermometry. In the course of a few months after a thermometer is filled and sealed, the bulb generally shrinks by some uncertain amount of from $\frac{1}{1000}$ to $\frac{1}{10000}$ of its bulk, sometimes even in the course of years to almost $\frac{1}{1000}$. This has been discovered by a general ranging of the freezing point, in new mercury thermometers generally as much as from 1° to $1^{\circ} 30'$ $^{\circ}\text{C}$, sometimes to as much as 1° , which corresponds to a shrinkage of $\frac{1}{10000}$, as the bulk expansion of mercury is when its temperature is raised from 0° to 100°C (Table II below) $\frac{1}{1000}$, or 0.0015, of its bulk at 0° . After a few months or a few years this progressive shrinkage ceases to be sensible, but if the thermometer at any time is exposed to the temperature of boiling water or any higher temperature, an abrupt sub-permanent enlargement of the bulb is produced, and the freezing point, if tested for by placing the thermometer in ice and water, is found to be lowered, then again for weeks or months or years there is a gradual shrinkage, as shown by a gradual rising of the freezing point when the thermometer is tested again and again by placing it in ice and water! A very delicate mercury thermometer, which has been kept for years at ordinary atmospheric pressures when out of use, and never when in experimental use exposed to any temperature higher than about 80°C , or much lower than the freezing point, becomes very constant, and probably may never show any change of as much as $\frac{1}{1000}$ of a degree. The freezing point or in its indication any other absolutely definite temperature, within some such range as from -20° or -10°C to $+80^{\circ}$ or $+40^{\circ}\text{C}$. But the abrupt and irregular changes, produced by exposing the thermometer to temperatures much above or much below some such limited range as that, constitute a very serious difficulty in the way of accurate thermometry by the mercury-in-glass thermometer

that in the nine years during which the instrument had remained undisturbed in the lecture-room a very sensible quantity of air (enough to render the temperature indication about 8°C too low) had leaked from the bulb through the sulphuric acid into the tube above the liquid column. This air was detected, and the instrument reset up for use, an operation completed in a minute at any time if need be. Some careful experiments were then made by Mr. Macfarlane to ascertain if the pressure of vapour or gas from the sulphuric acid, in the tube, was sensible, with a happily decisive result in the negative. The bulb, as kept at a very constant temperature by cold water, the uppermost few centimetres of the liquid column, and the whole of the tube above it, was heated to about 100°C by steam blown through a glass neck-tube, tilted round it for the purpose. The height of the manometric column remained sensibly unchanged! Further experiments must be made to ascertain whether or not there is enough of variation of absorption of the air by the sulphuric acid with variation of temperature, and enough of the consequent variation of pressure in the bulb, to vibrate sensibly the thermometric use of the instrument. If, as seems improbable, the answer to this question be unhappily affirmative, a satisfactory negative might be found by substituting hydrogen for common air.
